14585. KOEHLER, R. Description de deux Dorocidaris papillata anormaux provenant de Monaco. *Bull. Inst. Océanogr.* [*Monaco*] 1930(552): 1-10. 8 fig. 1930.—Detailed descriptions of an almost regular tetramerous specimen, and a strongly deformed pentameric specimen of *D. papillata* (Leske) [*Cidaris cidaris* (L.)] from off the coast of Monaco, depth unknown.—*E. Deichmann.*

14586. MERRIAM, CHARLES W. Notes on a brittle-star limestone from the Miocene of California. *Amer. Jour. Sci.* 21(124): 304-310. 2 fig. 1931.—This limestone, Santa Margarita in age, is composed of ophiuran skeletal debris deposited under littoral conditions. The name **OPHIURITES** (p. 306) is proposed for fossil vertebral ossicles. The low $MgCO_3$ content is compared with that of fossil crinoids.—*D. L. Frizzell.*

14587. MORTENSEN, TH. Bothriocidaris and the origin of echinoids. *Vidensk. Meddel. Dansk. Naturhist. For. Köbenhavn* 86: 93-122. 12 fig. 1928.—Discussion of the morphological structures of the Ordovician spp., *B. globulus* Eich. and *B. pahleni* Schmidt, which have been re-examined from specimens in the Mus. of Leningrad and Revel Mus., Dorpat, Esthonia. *B. archaica* Jackson is regarded as a synonym of *B. globulus. Bothriocidaris,* formerly considered an echinoid, is referred to Cystoidea, whereas the echinoids are considered as derived from primitive Edrioasteroidea.—*E. Deichmann.*

14588. PARKER, G. H. On certain feeding habits of the sea-urchin Arbacia. *Amer. Naturalist* 66(702): 95-96. 1 fig. 1932.—Record of *A. punctulata* capturing and devouring live fish (*Fundulus*).

14589. WANNER, JOH. Neue Beiträge zur Kenntnis der Permischen Echinodermen von Timor. *Wetenschapp. Mededeel. Dienst Mijnbouw Ned.-Indië. No. 11. I. Allagecrinus.* 1-34. 4 pl. II. Hypocrinites. 35-116. 7 pl., 16 fig. 1929.—Based on the collections of J. Venema, Basleo, Timor, now in Bandoeng, Java. The morphology of *Allagecrinus* is treated, comparison made with the Scottish forms, and diagnosis and key to 9 spp. given. *A.* jakovlevi* (p. 15); *A.* inflatus* (p. 18); *A.* acutus* (p. 19); *A.* procerus* (p. 21); *A.* quinquelobus* (p. 21); *A. indoaustralicus** Wann.; *A.* excavatus* (p. 24); *A.* quinquebrachiatus* (p. 25); *A.* ornatus* (p. 26).—A key to the 14 genera of the section Hypocrinites Wann., diagnosis, genotype, etc., given for some of the genera, and description of the examined spp. *Hypocrinus schneideri* Beyr. (p. 40); **CRANOCRINUS** (p. 41), with *C.* timoricus* (type) (p. 42), *C. turbinatus** Wann., and var. minor* (p. 48); **TENAGOCRINUS** (p. 48), *T.* sulcatus* (*Embryocrinus s.* Wann.) (p. 49); *Allosycocrinus* Wann., *A. pusillus** Wann.; *Monobrachiocrinus ficiformis** Wann., var. *elongata** Wann., var. carinata* (p. 62), var. *granulata* Wann.; *Abrachiocrinus* Wann., *A.* conicus* (p. 63), *A.* timoricus* (p. 64); *Embryocrinus hanieli** Wann.; *Acariaiocrinus* Wann., *A. clavulus** Wann., *A.* angulosus* (p. 74); *Hemistreptacron* Jak., *H.* carinatum* (p. 75), var. ornata (p. 78); *Coenecystis* Girty, *C.* angulosus* (p. 79), *C.* perforatus* (p. 80); **ATREMACRINUS** (p. 82), *A.* calyculus* (p. 83). A list of all known spp. of Hypocrinites with their occurrence, the morphological features of the group, and a table with their supposed genetic relations are given.—*E. Deichmann.*

On Doliopsis c. and its occurrence in the Adriatic.]** *Atti R. Ist. Veneto Sci. Lett. ed Arti* 90(3/4): 147-153. 2 pl. 1930/1931.—*D. crosseana**, described from a single specimen, is maintained as valid, and a 2nd specimen* is described.

14591. **CRICKMAY, COLIN H. The Jurassic rocks of Askcroft, British Columbia.** *Univ. California Publ. Bull. Dept. Geol. Sci.* 19(2): 23-74. 1 map., 6 pl. 1930.—Description of Up. Triassic and Middle and Up. Jurassic rocks and their fossils in a small area in the interior plateau of southern Brit. Columbia and elsewhere. Faunal lists follow. Up. Triassic: *Paratropites* **spepsumensis*** (p. 60) (Cephalopoda). Early Middle Jurassic—Sonninian, *"discitae"* (date according to Buckman biological chronology); **KRATEROSTROBILOS** (Coelenterata, Anthozoa, Turbinoliidae), type *K.* **bathys*** (p. 40); *Isocrinus californicus* Clark (Echinodermata); *Kallirhynchia* sp. and *Ewidothyris* **francescalaurae*** (p. 42) (Brachiopoda); (Mollusca) *"Trigonia"* sp.; *Chlamys* **paideios*** (p. 54); **PARAPECTEN** (Pectinidae), type *P.* **ntlakapamuxanus*** (p. 55); *Entolium* **semlini*** (p. 56); *Gryphaea* **minutula*** (p. 49); *Goniomya* sp.; *Homomya* **jurozephyriensis*** (p. 58); *Fontannesia* cf. *carinata* Buckman. Early Middle Jurassic—Sonninian, pre-*sauzei: Vaugonia* sp.; *Entolium semlini* Crickmay; *Modiolus* sp.; *Pleuromya* **rhynchophora*** (p. 57); *Pseudomelania* sp. Early Middle Jurassic—Sonninian, *sauzei:* **ARCHAEODON** (Pelecypoda, Parallelodontidae), type *A.* **phylarchus*** (p. 42); **ASHCROFTIA** (Parallelodontidae), type *A.* **inversidentata*** (p. 43); **GILBERTWHITEA** (Parallelodontidae) type *G.* **similima** (*Arca s.* Whiteaves) (p. 46); *G.* **micromorpha*** (p. 46); *Grammatodon* **semiornatus*** (p. 46); *G.* **sonninianus*** (p. 47); *Pinna* **amblyrhyncha*** (p. 47); *Gervillia* **ashcroftensis*** (p. 48); *Gryphaea* **patera*** (p. 51); **SCHAPHOGONIA** (Trigoniidae), type *S.* **argo*** (p. 52); *Entolium* cf. *semlini* Crickmay; *Modiolus* **sphenoproratus*** (p. 56); *Pleuromya* **scutalisensis*** (p. 57); *P.* **chlutosensis*** (p. 58); *Astarte* **sonniniarum*** (p. 59); *Pseudomelania* sp.; *"Fontannesia"* sp.; *"Sphaeroceras"* sp.; *Kallistephanus* sp. Early Upper Jurassic—Proplanulitan: *"Aucella"* sp.; *"Torricellites"* sp.; *"Gowericeras"* sp.; *"Catasigaloceras"* sp. Early Up. Jurassic fossils from northern Brit. Columbia: **VAUGONIA** (Trigoniidae), type *V.* **veronica*** (p. 53); *V.* **mariajosephinae*** (p. 54). Pedaliidae is substituted for Pedelionidae Stephenson, olim Pernidae. **HAIDAIA** (Trigoniidae), type *Trigonia dawsoni* Whiteaves, is also proposed. Discussion of catamorphism, with examples from Parallelodontidae, etc. Discussion of micromorphism with example of *Gryphaea minutula.*—*C. H. Crickmay.*

14592. **DELÉPINE, G. Sur la présence de Cymaclymenia camerata Schindewolf dans la zone d'Etroeungt à Sémeries (Nord de la France).** *Ann. Soc. Geol. du Nord* 54: 99-103. 1 pl. 1 fig. 1929.

14593. **DUTERTRE, A. P. Metoicoceras pontieri dans le Sud du Boulonnais.** *Ann. Soc. Geol. du Nord* 55: 220-221. 1 fig. 1930.—Describes this ammonite from the Touronian at Boulonnais, North of France.—*W. Berry.*

14594. **FINLAY, H. J. On Turbo postulatus Bartrum; Does it indicate a Pliocene connection with Australia?** *Trans. and Proc. New Zealand Inst.* 62(1): 1-6. 1931.—*Heligmope* **postulatus** (*Turbo p.* Bartrum) (p. 5) permits the fixing of a Lower Pliocene base-line from which the correlations of higher and lower beds on either side of the Tasman may be surveyed. *Heligmope* **pehuensis** (*Lippistes p.* Marwick) (p. 5). *Heligmope* is referred to the Ianthinidae.

14595. **FINLAY, H. J. On Austrosassia, Austroharpa, and Austrolithes, new genera; with some remarks on the gasteropod protoconch.** *Trans. and Proc. New Zealand Inst.* 62(1): 7-19. 1931.—**AUSTROSASSIA** (p. 7), an Eocene genus in Cymatiidae, still existing, type *Septa parkinsonia* Perry; *A.* **procera** (p. 10), n. n. for *Triton minimus* Hutton; *A.* **reticulata** (*Streptosiphon* (*Streptopelma*) *reticulatum* Suter=*Cymatium marwicki* Finlay) (p. 10); *Austrotriton maorium, insignitum, cyphoides,* and *decagonia* are referred to *Austrosassia* (p. 10); **AUSTROHARPA** (p. 11) (Harpidae), type *Harpa pulligera* Tate; *H. punctata* Verco, *H. spirata* Tate, *H. abbreviata* Tate, *H. tenuis* Tate, and ? *H. clathrata* Tate are referred to *Austroharpa; A.* **tatei** (p. 14), older Pliocene, So. Australia; **AUSTROLITHES** (p. 14) (Colidae), type *Fusus bulbodes* Tate as restricted by Pritchard. *Clavella platystropha* Pritch., *F. tateanus* T.-W., and *F. incompositus* are referred to *Austrolithes* (p. 15); *Pelicaria* **marwicki** (p. 17), "older Pliocene" of So. Australia. The writer finds the scaphelloid or pseudoscaphelloid apex more common in Mollusca than was thought, and here discusses it in Cymatiidae, Harpidae, Colidae, and Struthiolariidae. He regards the protoconch as of considerable importance in palaeontology. Types are in author's coll.

14596. **FLETCHER, HAROLD O.** (Introduction by **W. S. DUN.**) **Contributions on the Permo-Carboniferous Aviculopectinidae of New South Wales.** *Rec. Australian Mus.* 17(1): 1-34. 16 pl. 6 fig. 1929.—The introduction describes Varney Parkes collection, of which the material here described is a part, and other collections, and notes large size of aviculopectens and deltopectens from Australia. Dun also discusses differences between *Deltopecten* and *Aviculopecten* and gives registration numbers of specimens of Avidulopectinidae in the Mining and Geol. Mus. at Sydney, and in the Australian Mus. Fletcher describes 21 spp. from "Nowra grits," Up. Marine series of the Permo-Carboniferous, from N. S. Wales (specimens of *Deltopecten comptus* (Dana) are also from western Australia and of *Aviculopecten squamuliferus* (Morris) also from Tasmania) including: *Aviculopecten* **extensus*** (p. 6); *A.* **multicostatus*** (p. 8); *A.* **gracilis*** (p. 11); *A.* **parkesi*** (p. 13); *Deltopecten* **media*** (*Aviculopecten m.* Laseron (part)) (p. 15); *D.* **depressus*** (p. 18); *D. leniusculus** Dana (=*D. rienitsi* Mitchell); *D.* **comptus*** (*Pecten c.* Dana) (p. 23); *D.* **clarkei*** (p. 28); *Deltopecten* sp.*, probably new (p. 29); *D. subquinquelineatus* v. **delicatula*** (p. 31); *D.* **lata*** (p. 32). The remaining 9 spp. belong either to *Aviculopecten* or *Deltopecten* and 4 of them are redescribed. Types of new spp. in Australian Mus., Sydney.—*J. S. Williams.*

14597. **FLETCHER, HAROLD O.** (Introduction by **W. S. DUN**). **A revision of the genus Astartila.** *Rec. Australian Mus.* 17(2): 53-75. 5 pl. 1929.—The introduction gives history and diagnosis of the genus; 18 spp. are described and figured, all from Permo-Carboniferous (Up. Marine series) of New So. Wales. Types of new spp. in Australian Mus., Sydney. *A.* **danai** (*Pachydomus d.* DeKoninck) (p. 55); *A.* **compressa*** (p. 58); *A. cyprina** Dana and *A. polita** Dana, placed in the genus *Pachydomus* by DeKoninck, are referred back to *Astartila* by Fletcher. *A.* **obliqua*** (p. 61); *A.* **parkesi*** (p. 63); *A. intrepida** Dana (=*Pachydomus*

ovalis (?) McCoy); *A.* **ovata*** (p. 69); *A.* **quadrata*** (p. 70); *A.* **delicatula*** (p. 71); *A.* **pusilla*** (*Pachydomus pusillus* McCoy) (p. 72); *A.* **centralis*** (p. 73); *A.* **subcarinata*** (p. 74); *A.* **subgemma*** (p. 74). Additional notes are given on the following which comprise the remainder of the 18 spp. treated: *A. cytherea** Dana; *A. corpulenta** Dana; *A. cyclas** Dana; *A. transversa** Dana.—*J. S. Williams.*

14598. **GAMBETTA, LAURA. Risultati zoologici della Missione inviata dalla R. Società Geografica Italiana per l'esplorazione dell'oasi di Giarabub (1926-1927). La Malacofauna del lago Arrascía. [Zoological results from the oasis of Jarabub. The mollusks of Lake Arrascia.]** *Ann. Mus. Civ. Storia Nat.* [*Genova*] 53: 265-298. 2 Maps, 8 fig. 1928-1930.—Three living marine mollusks from Lake Arrascia are described: *Pirenella conica* v. *fusca* Pallary, *Mytilus minimus* v. **coeni*** (p. 271), *Cardium edule-rectidens* v. **arrasciensis*** (p. 294). The shell modifications of the new varieties are attributed to the action of environmental waters. Maps show the distribution of *C. edule* in the Atlantic and (contrary to some) in the Mediterranean.—*L. Gambetta* (*transl. by H. Federighi*).

14599. **GATLIFF, J. H., and C. J. GABRIEL. Additions to and alterations in the catalogue of Victorian Marine Mollusca.** *Proc. Roy. Soc. Victoria* 43(2): 202-232. 1931.—The synonymy of 168 spp. is brought up to date. *Marita* Hedley is removed from *Guraleus* and raised to generic rank; *Xenophalium* Iredale (=*Xenogalea* Iredale).

14600. **GRIMPE, G. Teuthologische Mitteilungen. XIII. Über die Cephalopoden der Sunda-Expedition Rensch.** *Zool. Anz.* 95(5/8): 149-174. 14 fig. 1931.—*Abralia* **renschi*** ♀ (p. 149), Sumatra; **STENABRALIA** (p. 150, 164), n. subg. in *Abralia*, erected for *A. renschi, A. steindachneri, A. astrolineata,* and *A. astrosticta; Idiosepius pygmaeus* ssp. **hebereri*** (p. 165), Lombok Isl., compared with *I. p. pygmaeus** and *I. p. paradoxus.* Types in Zool. Mus. Berlin.

14601. **JACOT, ARTHUR PAUL. Rheotropism and evolution.** *Peking Soc. Nat. Hist. Bull.* 5(3): 39-40. 1931.—The mollusks *Eulota ravida* and *Cathaica pyrrhozona* are essentially plain forms and are not strongly rheotropic, ascending under other stimuli; *C. yantaiensis* though active during rains does not ascend at all. On the other hand certain species found in the hills appear to be rheotropic.

14602. **KENNARD, A. S., A. E. SALISBURY, and B. B. WOODWARD. The types of Lamarck's genera of shells as selected by J. G. Children in 1823.** *Smithsonian Misc. Coll.* 82(17): 1-40. 1931.—The dates of Children's rare little work "Lamarck's genera of shells, etc." are given as Oct. 1822 to Jan. 1824. Children used "type" in the modern sense, but some of his designations are not valid, because of earlier designations or non-inclusion in the original description. The writers comment on Children's fixations of the types of 212 genera found in Lamarck's "Histoire" (1818-22) and settle the status of each genus. The following designations must date from Children: *Clavagella* Lam., type *C. echinata; Gastrochaena* Sprengl., type *G. cuneiformis; Glycimeris* Lam. (1818) not Da Costa (1778), type *G. siliqua; Solemya* Lam. (=*Solenomya* Lam.), type *S. togata* Poli (=*S. mediterranea* Lam.); *Amphidesma* Lam., type *A. variegata; Saxicava* Fleur., type *Mytilus rugosus* L., *Venerupis* Lam., type *Venus perforans* Montag.; *Psammobia* Lam., type *P. feroensis* (Gmelin); *Psammotaea* Lam., type *P. donacina; Corbis* Lam., type *C. fimbriata; Cyrena* Lam., type *C. cor; Venericardia* Lam., type *V. planicosta; Cardita* Brug., type *C. sulcata; Hyria* Lam., type *H. avicularis; Etheria* Lam., type *E. semilunata; Podopsis* Lam., type *P. truncata; Gryphaea* Lam., type *G. angulata; Helicina* Lam., type *H. neritella; Navicella* Lam., type *N. tessellata; Tornatella* Lam., type *T. flammea* Gmel.; *Planaxis* Lam., type *P. sulcata.* The authors are responsible for the selection of the type of *Avicula* Brug. as *A. hirundo.*

14603. **KURODA, TOKUBEI. New Japanese shells (3).** *The Venus* [*Japan*] 2(6): 314-318. 1 pl. 1931.—The following spp. were illustrated and named in vol. II, no. 1, May 30, 1930, plate I from which publication they will date, but they are here described for the first time: *Thais* (*Mancinella*) *lata, T.* (*M.*) *siro,* and *Coralliophila sugimotonis.*

14604. **KURONUMA, KATSUZÔ. On the Japanese ship-worms, with descriptions of three new species.** *The Venus* [*Japan*] 2(6): 294-304. 2 pl. 1931.—Reports on 9 spp., including *Teredo* (*Lyrodus*) **hibicola*** (p. 295), *T.* (*Teredops*) **tateyamensis*** (p. 295), *Bankia* (*B.*) **nakazawai*** (p. 296).

14605. **LAIDLAW, F. F. Note on Ariophanta (Microcystis) normani, Smith, from Christmas Island.** *Proc. Malac. Soc. London* 19(4): 176. 1931.—Anatomical and radular notes are given; these show that the species belongs in the Durgellinae, near *Sitala.*—*H. B. Baker.*

14606. **LAIS, ROBERT. Die Molluskenfauna des Alpersbacher Stollens im südlichen Schwarzwald. I. Beitrag zur Molluskenkunde Südwestdeutschlands.** *Arch. Molluskenk.* 63(2): 53-70. 1 pl. 1931.—A list of mollusks from non-calcareous soils is given and the problem of the population of isolated calcareous areas is discussed.—*H. B. Baker.*

14607. **LAMY, ED. Sur une coquille de la Mer Rouge: Prasina borbonica Deshayes.** *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(4): 272-277. 1 fig. 1928.—A review of the literature on *P. borbonica**, which is compared with *P. cornuta**.

14608. **LAMY, ED. Les Pinnidés de la Mer Rouge (d'après les matériaux recueillis par le Dr. Jousseaume).** *Bull. Mus. Nation. Hist. Nat. Paris* 1928(5): 352-354. 1928.—Notes on 5 spp. of *Pinna.*

14609. **LAMY, ED. Les Avicules de la Mer Rouge (d'après les matériaux recueillis par le Dr. Jousseaume).** *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(1): 111-116. 1929.—Notes on 12 spp. of *Pteria: P.* **aegyptiaca** (*Avicula a.* Chemn) (p. 111); *P.* **zebra** (*A. z.* Reeve) (p. 112); *P.* (*Electroma*) **ala-corvi** (*Mytilus a.* Dillwyn) (p. 112); *P.* (*E.*) **spadicea** (*Avicula s.* Dunker) (p. 112); *P.* (*Pinctada*) **margaritifera** (*Mytilus margaritiferus* L.) (p. 113); *P.* (*P.*) *m.* var. **eythraensis** (Jameson) n. comb. (p. 113); *P.* (*P.*) **reentsi** (*A. r.* Dunker) (p. 113); *P.* (*P.*) **vulgaris** (*Perlamater v.* Schumacher) (p. 114); *P.* (*P.*) **lentiginosa** (*A. l.* Reeve) (p. 115); *P.* (*P.*) **cetra** (*A. c.* Reeve) (p. 115); *P.* (*P.*) **crocata** (*A. c.* Swainson) (p. 115); *P.* (*P.*) **nigra** (*A. n.* Gould) (p. 116); *P.* (*P.*) **placunoides** (*A. p.* Reeve) (p. 116).

14610. **LAMY, ED. Les Malleacea de la Mer Rouge. (D'après les matériaux recueillis par le Dr. Jousseaume.)** *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(2): 150-156. 1929.—Synonymical and distributional data on *Malleus savignyi, M.* (*Malvufundus*) *regula, M.* (*M.*) *decurtatus, M.* (*M.*) *legumen, Vulsella rugosa, V. vulsella, V. spongiarum, V. attenuata, Crenatula picta, Melina legumen,* and *M. australica.*

14611. **LAMY, EDOUARD. Révision des Limidae vivants du Muséum National d'Histoire Naturelle de Paris. (Suite et fin.)** *Jour. de Conch.* 74(3): 169-198. 1 pl. 1930; (4): 245-269. 1930.—These 2 parts finish the discussion of *Lima* (subg. *Mantellum, Limatulella, Acesta, Ctenoides,* and *Limatula*) and treat also the genus *Limea. Lima* (*Mantellum*) **orbignyi** (p. 180), n. n. for *L. angulata* Sow.; *L.* (*Ctenoides*) **lischkei** (p. 196), n. n. for *L. dunkeri* Smith.—*H. B. Baker.*

14612. **LØYNING, PAUL. Benthoctopus sibiricus, a supposed new species of Cephalopoda from the Siberian Arctic Ocean.** *Meddelel. Zool. Mus. Oslo No. 21* (*Norw. North Polar Exp. with the "Maud" 1918-1925, Sci. Results, 5, no. 11*) 1-11. Map. 2 pl., 2 fig. 1930.—*B.* **sibiricus*** (p. 1), description based chiefly on characters of radula and hectocotylus, from fragment taken from a walrus stomach, in 38 m., 76° 12′ N., 146° 10′ E., N. of the New Siberian Isls.—*S. S. Berry.*

14613. **MacGINITIE, G. E. The egg-laying process of the gastropod Alectrion fossatus Gould.** *Ann. and Mag. Nat. Hist.* 8(45): 258-261. 4 fig. 1931.—The use of the

pedal gland in the process of oviposition is illustrated.

14614. **MAKIYAMA, JIRÔ.** On Arca kiyonoi n. sp. *The Venus* [*Japan*] 2(6): 269-277. 8 fig. 1931.—*A.* kiyonoi* (p. 269), from Post-Pleistocene deposits in Mikawa and Ettyû provinces, Japan, also living in China Sea.

14615. **MERCIER, JEAN.** À propos des variations de l'aire ligamentaire d'Ostrea wiltonensis Lyc. et du genre Pernostrea Munier-Chalmas. *Bull. Soc. Linn. Normandie* 1: Trav. Orig. 3-7. 1 fig. 1928(1929).

14616. **MERCIER, L.** À propos de "La présence de Cyclostoma elegans Müller dans la région littorale du Bessin." *Bull. Soc. Linn. Normandie* 1: 5. 1928(1929).

14617. **MORIN, G., et A. JULLIEN.** Histophysiologie de l'organe de Bojanus au cours de l'estivation artificielle chez Helix pisana. *Bull. Histol. Appl. Phys. et Path.* 7(7): 220-232. 3 fig. 1930.—Aestivation was produced through desiccation and the excretory epithelium was studied. Normally the cells are cylindrical, distinct, with basal vesicular nuclei and distal globular ends. They have abundant filamentous mitochondria about the basal end and the sides. After 21 days mitochondria are reduced to a few round granules, the cells form a syncytial mass with very eccentric nuclei and the cytoplasm is vacuolated. After 62 days the epithelium cannot be distinguished from the adjacent connective tissue since both enter into a 2-layered structure. Large coarse mitochondrial rods are again found in the cell borders. This shows that the organ is in continuous or accentuated activity during aestivation.—*J. G. Sinclair.*

14618. **MÜLLER, WILHELM.** Die Fauna der Frasnes-Stufe bei Almáden (Sierra Morena, Spanien). *Abhandl. Senckenberg. Naturf. Ges.* 41(5): 247-282. 4 pl. 1929.—The material collected is from the Frasnian (Devonian) deposits. The collection comprises 36 spp. belonging to the following groups: Brachiopoda, Lamellibranchia, Gastropoda, Pteropoda, Bryozoa, Cephalopoda, Echinoderma, and Crustacea. The spp. are fully described and figured. Lamellibranchia: *Aviculopecten* unnamed n. sp. ? (p. 265); *Lyriopecten* 2 unnamed n. spp. ? (one figured) (p. 266); *Leptodesma* almadenensis* (p. 266); *Leptodesma* unnamed n. sp.* (p. 267); *Avicula* ? (*Dolabra* ?) hispanica* (p. 268); *Modiola* supradevonica* (p. 269); *Cypricardella* oblonga* (p. 269); *Nuculana* acuta* (p. 270); *Ctenodonta* robustella* (p. 270); *Cucullella* planiforma* (p. 271); *Myophoria* rotunda* (p. 272); *Carydium* beushauseni* (p. 272); *Grammysia* unnamed new sp.* (p. 274). Tables are given showing: (1) The distribution of the spp. in the 5 different beds of the series; (2) a comparison of the distribution of the same spp. in the Dinant Basin and the Boulonnais.—*M. L. Hett.*

14619. **NATHAN, HANS.** Eine zwischeneiszeitliche Mollusken-Fauna aus Südbayern. *Abhandl. Geol. Landesuntersuch. Bayerischen Oberbergamtes Hft. 3.* p. 31-41. 2 pl. 1931.—Thirty-six gastropods and 1 pelecypod are listed, with descriptive and distributional notes, and a local geographical analysis is given. The fauna is comprised of northern, southern, and eastern elements, and represents the "Riss-Würm" interglacial epoch.

14620. **OPPL, EGON.** Ueber einige Makrofossilien der Wigantitzer Klippe bei Roschnau unter dem Radhost. *Naturwiss. Zeitschr. Lotos* 78(2): 107-109. 1930.—*Lamellaptychus beyrichi* and *Punctaptychus punctatus,* the first macrofossils to be recorded from this formation, furnish new evidence of its Tithonian age (Jurassic). Three undetermined spp. of *Belemnites* are also recorded.

14621. **PARONA, C. F.** Ricerche sulle rudiste e su altri fossili del Cretacico Superiore del Carso Goriziano e dell' Istria. [Rudistids and other Upper Cretaceous fossils of Carso Goriziano and Istria, Italy.] In: *Mem. Ist. Geol. R. Univ. Padova* 7: 1-56. (separately paged) 6 pl., 8 fig. 1926.—A cross-section showing the structure and fossiliferous horizons, and a discussion of the stratigraphy and paleontology precede the systematic section. There are descriptions and taxonomic notes on 54 spp. belonging to 16 genera of rudistids, and 12 other spp. of pelecypods belonging to 6 genera, as well as 1 gastropod and 2 brachiopods from the Senonian and Turonian. *Radiolites* cremai* (p. 28); *R.* depressa* (*Caprinella d.* Cornalia & Chiozza) (p. 30); *Requienia* calegarii* (p. 43); *Alectryonia* polae* (p. 51). All new spp. from the Turonian.

14622. **PATTON, LEROY T.** The geology of Stonewall County, Texas. *Univ. Texas Bull.* 3027. p. 3-77. Map, 4 fig. 1930.—A unique association of a new sp. of *Ostrea* with *Pleurocera strombiformis, Exogyra texana,* and *Gryphaca pitcheri* in strata referred to the Trinity or possibly a transition to the Comanche group, is noted.

14623. **REED, F. R. COWPER.** Some new lamellibranchs from the Silurian of the Ludlow district [England]. *Ann. and Mag. Nat. Hist.* 8(46): 289-304. 3 pl. 1931.—*Tancrediopsis* ludensis* (p. 289); *Maminka* (*Matercula*) anglica* (p. 290), first record of the genus in the British Silurian; *Dualina* impersonata* (p. 291); *Chaenocardiola* marstoni* (p. 292); *Lunulicardium* relegatum* (p. 293); *Grammysia* morata* (p. 294); *Rhytimya* (?) lineata* (p. 295); *Endolasma* (?) protractum* (p. 296); SALWEYIA (p. 301), new subg. of *Euthydesma* ?, type *E.* ? (*S.*) subobliquatum* (p. 298); *Pterinea* aymestriensis* (p. 301); *P.* nupera* (p. 302). Types in Ludlow Mus.

14624. **RENSCH, ILSE.** Beitrag zur Kenntnis der Schneckenfauna der Admiralitätinseln. *Zool. Anz.* 95 (5/8): 186-194. 5 fig. 1931.—*Papuina* pulcherrima* (p. 187); *P.* klaarwateri* (p. 187); *P.* admiralitatis* (p. 188); *P. novaecgeorgiensis* (Cox) (=*Helix* (*Geotrochus*) *moscleyi* E. A. Smith); *Chloritis* (*Eustomopsis*) dentrecasteauxi (*Helix* (*C.*) *d.* E. A. Smith) (p. 190); *Hemiplecta* cartereti (*Helix c.* E. A. Smith) (p. 191); *Dendrotrochus helicinoides* labillardierei (*Helix* (*Geotrochus*) *l.* E. A. Smith) (p. 191); *Ganesella* infrastriata (*Helix i.* E. A. Smith) (p. 192); *G.* (?) modesta* (p. 192). All from Admiralty Isl.; types in Zool. Mus. Berlin.

14625. **ROCH, FELIX, und FRIEDRICH MOLL.** Die Terediniden der Zoologischen Museen zu Berlin und Hamburg. *Mitteil. Zool. Staatsinst. u. Zool. Mus., Hamburg* 44: 1-22. 2 pl., 20 fig. 1931.—Full synonymy is given for each species; the palette of 41 spp. and the shells of 13 n. spp., are illustrated. *Teredo megotara* Hanley (=*T. denticulata* Gray); *T. m.* var. antarctica (*T. a.* Hutton) (p. 5); *T.* gazellae* Roch (p. 6), Malay Arch.; *T.* diederichseni* Roch (p. 6), between Manila and Sunda Strait, type in Hamburg Mus.; *T.* petersi* Moll (p. 6), Kerimba Isl., Portuguese E. Africa; *T.* semoni Moll (*T. clava* Martens) (p. 9); *T.* yatsui* Moll (p. 10), Japan; *T.* lamyi* Roch (p. 10), Italy, type in Hamburg Mus.; *T.* takanoshimensis* Roch (p. 10), Japan [type dep. not given]; *T.* togoensis* Roch (p. 11) and *T.* lomensis* Roch (p. 11), Togo; *T.* franziusi* Roch (p. 11), Mediterranean Sea; *T.* sinensis* Roch (p. 13), China; *T.* nodosa* Roch (p. 14), Italy; *T.* dicroa* Roch (p. 14), Togo; *T.* hermitensis* Roch (p. 14), Hermit Isl., Bismarck Arch.; *Nausitoria* orientalis* Roch (p. 17) and *N.* kamiyai* Roch (p. 17), Japan; *Bankia* bagidaensis* Roch (p. 18) and *B.* anechoensis* Roch (p. 18), Togo; *B.* kuronunii* Roch (p. 19) and *B.* kingyokuensis* Roch (p. 20), Japan; *B.* segaruensis* Roch (p. 20), Togo. Except where otherwise given, types are in Berlin Zool. Mus.

14626. **ROSZKOWSKI, WACŁAW.** Contributions to the study of the family Lymnaeidae. 1. On the systematic position and the geographical distribution of the genus Myxas J. Sowerby. *Prace Państwowego Muz. Zool.* (*Ann. Mus. Zool. Polonici*) 8(2): 64-97. 5 pl. 1929.—On the basis of a detailed anatomical study of *Myxas glutinosa,* the author decides that this genus should be retained in the Lymnaeidae. Records of its distribution are also collated.—*H. B. Baker.*

14627. **RUTSCH, R.** Einige interessante Gastropoden aus dem Tertiär der Staaten Falcón und Lara (Venezuela). *Eclogae Geol. Helvetiae* 23(2): 604-614. 1 pl. 1930.—Four gastropods are figured and described in-

cluding *Scobinella morieri* v. **gavilanensis*** (p. 611), from the Pliocene.—*W. Berry.*

14628. SASAKI, MADOKA. A monograph of the dibranchiate cephalopods of the Japanese and adjacent waters. [A posthumous paper.] *Jour. Fac. Agric. Hokkaido Imp. Univ. Sapporo* 20 (Supplem.): 1-357. 30 pl. (1 col.), 179 fig. 1929.—This paper, the plates of which are issued in a separate volume, is based on a 10 year study of material contained in 9 different collections, comprising about 10,000 specimens. The spp. herein described amount to 125, in 52 genera, of 21 families, of which 2 families, 3 genera, 1 subg., 53 spp., and 7 varieties are new to science. A key is given to the families and subfamilies (found in Japan), there are also numerous keys to genera and spp., and tables of measurements of ♂ and ♀ species. All spp. are figured. In the suborder Octopoda, the following nomenclatorial changes occur: Division **PINNATTA** n. n. (Lioglossa Lütken) (p. 4); subdivision **PROTOPINNATA** n. n. (Eurytreta Grimpe) (p. 4), containing Wataselliidae; subdivision **METAPINNATA** n. n. (Stenotreta Grimpe) (p. 6), containing Cirroteuthidae; a synopsis of the 6 genera of this genus is appended; division **APINNA** n. n. (Trachyglossa Lütken) (p. 12), containing Eledonellidae, with *Eledonella* **ijimai*** (p. 13), Kyushu, Japan, type in Tokyo Imp. Univ.; Amphitretidae, Allopsidae, Argonautidae, and Polypodidae with *Polypus* **oshimai*** (p. 44), Formosa and *P.* **luteus*** (p. 45), Pescadores; *P. jan-siao* v. **typicus*** (p. 49), Japan [type dep. not given]; *P. f.* var. **etchuanus*** (p. 53), Kyushu; *P.* **fasciatus*** (*P. pictus* ssp. *f.* Berry) (p. 58); *P.* **fujitai*** (p. 70), Japan; *P. döfleini** Wülker (=*P. apollyon* Berry); *P.* **tenuicirrus*** (p. 78), Japan, type in Tokyo Imp. Univ.; *P.* **hattai*** (p. 87), Japan; *P.* **variabilis*** (p. 90), and var. **typicus*** (p. 90), Japan; *P. v.* var. **pardalis*** (p. 94), Japan, type in Tokyo Imp. Univ. In the suborder Decapoda, Loliginidae, the following nomencl. changes occur: *Loligo edulis* Hoyle (=*L. budo* Okada); *L. e.* forms **nagasakensis*** and **grandipes** (p. 109), Japan [type dep. not given]; *L.* **formosana*** (p. 109), Formosa; *L.* **gotoi*** (p. 116), Kyushu; *L.* **tagoi*** (p. 118), Japan, type in Tokyo Imp. Univ.; *L.* **beka*** (p. 121), Japan; *L.* **oshimai*** (p. 123), Formosa. Idiosepiidae: A synopsis of the 4 spp. of the genus *Idiosepius* is appended. Sepiolidae: *Euprymna* **berryi*** (p. 143), all Japan (except Hokkaido), Formosa, Hongkong, Philippines, Andaman Isls., Kolumadulu Atoll (Indian Sea), Ceylon. Sepiidae: *Sepia* **tigris*** (p. 168), Formosa, type in Formosan Mus.; *S.* **robsoni*** (p. 179), Tokyo Bay, type in Tokyo Imp. Univ.; *S.* **erostrata*** (p. 183), Kyushu, type in Tokyo Imp. Univ.; *S.* **tenuipes*** (p. 193), Honshu, type in Tokyo Imp. Univ.; *S. kobiensis* v. **typica*** (p. 204), south of Kyushu [no type loc. given]; *S. k.* var. **andreanoides*** (*S. a.* Hoyle) (p. 206); *S. k.* var. **toyamensis*** (p. 209), Toyama Bay, Honshu; *S. k.* var. **beppuana*** (p. 211), Bungo Prov., type in Tokyo Imp. Univ.; *S. k.* var. **crassa*** (p. 213), Surugu Prov., type in Tokyo Imp. Univ.; *Sepiella* **japonica*** (p. 219), Etchû Prov.; *S.* **heylei*** n. n. (p. 221). Enoploteuthidae: *Abralia* **multihamata*** (p. 245), Formosa, type in Formosan Mus. Chiroteuthidae: **TANKAIA** (p. 308) subg. of *Chiroteuthis*, type *C.* (*T.*) **borealis*** (p. 309), Kushiro Prov., type in Fish. Inst. Takashima, Hokkaido; *Mastigoteuthis* **latipinna*** (*Idioteuthis l.* Sasaki) (p. 312). Cranchiidae: *Teuthowenia* **tagoi*** (p. 326), Suruga Prov., type in Tokyo Imp. Univ.; *T.* **elongata*** (p. 327), Kyushu, type in Tokyo Imp. Univ. An extensive bibliographical list concludes the paper. Except where otherwise given, types of new forms are in Hokkaido Imp. Univ.

14629. SAYRE, ALBERT NELSON. The fauna of the Drum limestone of Kansas and Western Missouri. *Bull. Univ. Kansas, Sci. Bull.* 19 (2): 75-203. 21 pl. 1930; simultaneously published in Bull. Univ. Kansas, State Geol. Surv. Kansas, Bull. 17. p. 75-203. 21 pl. 1930.—The molluscan fauna of the Drum limestone presents a sharp contrast to those of the preceding and succeeding limestones of the Pennsylvanian system of Kansas. Bryozoa: *Fenestella mimica* v. **latirama*** (p. 88), *F.* **moorei*** (p. 89), *Polypora submarginata* v. **nodosa*** (p. 90), *Rhabdomeson* **kansasense*** (p. 91). Brachiopoda: *Productus insinuatus* v. **missouriensis*** (p. 94) and *Dielasma* **ventricosa*** (p. 98), Missouri and Kansas. Pelecypoda: *Edmondia* (?) **kansasensis*** (p. 104); *Nucula* **triangularis*** (p. 105); *Parallelodon* **kansasensis*** (p. 108), *Pteria* **welleri*** (p. 110), *Pseudomonotis* **spinosa*** (p. 114) and *Myalina* (?) **slocomi*** (p. 117), Kansas and Missouri; *Schizodus* **trigonalis*** (p. 118); *Lithophaga* **subelliptica*** (p. 123); *Pleurophorus* **attenuatus*** (p. 125); *P.* **turnerensis*** (p. 126). Gastropoda: *Pleurotomaria* **bilineata*** (p. 132), Missouri; *P.* **fisheri*** (p. 133); *P.* **kansasensis*** (p. 134); *Ptychomphalus* **laudenslageri*** (p. 134); *P.* **lineata*** (p. 135); *Murchisonia* **matheri*** (p. 135); *Goniospira* **helicaformis*** (p. 136); *Phanerotrema* **ornatum*** (p. 136); *Microdoma* **ornatus*** (p. 140); *Naticopsis* (?) **minuta*** (p. 142); *Hemizyga* (?) **cancellata*** (p. 145); *Bulimorpha* **meeki*** (p. 146), n. n. for *Actaeonima minuta* Meek & Worthen; *B.* **turnerensis*** (p. 147); *Aclisina* **breva*** (p. 150); *A.* **parallela*** (p. 150); *Orthonema* **liratum*** (p. 151); *Trachydomia* **pustulosa*** (p. 152), Kansas and Missouri. Cephalopoda: *Orthoceras* **kansasense*** (p. 153), Missouri and Kansas; *Metacoceras cavatiforme**, *M. c.* var. **angulatum** (p. 155), Missouri. Except where otherwise given, new spp. are from Kansas. Types in Geol. Mus. Univ. Kansas. Various other spp. in Foraminifera, Alcyonaria, Zoantharia, Annelida, Bryozoa, Brachiopoda, Pelecypoda, Gastropoda, Cephalopoda, and Trilobita are described from collected material and illustrated.

14630. SCHERMER, ERNST. Die Molluskenfauna der ostholsteinischen Seen. *Arch. Hydrobiol.* 22 (2): 259-305. 4 pl., 1 fig. 1930.—This survey includes studies on 33 east Holstein lakes; 48 species were obtained; for all of these, notes on the distribution through the series and in the individual lakes, dimensions of the various forms and other peculiarities are discussed. *Bithynia leachi* f. **gracilis*** (p. 288).—*H. B. Baker.*

14631. SCHILDER, F. A. Gesetzmässigkeiten und Ursachen der Schalen-Variabilität bei Cypraea. *Xe. Congrès Internation. Zool. à Budapest, 1927.* Part 2. 980-990. 1929.—The principal variations in size, shape, number of folds, and color (ground, stripes and spots) are discussed and illustrated by statistical tables for examples. Surveys of known variation in the species are also presented.—*H. B. Baker.*

14632. SPATH, L. F. Revision of the Jurassic cephalopod fauna of Kachh (Cutch): Part III. *Mem. Geol. Surv. India; Palaeont. Indica.* 9 (Mem. 2): 163-278. 28 pl. 1928.—Deals with Up. Jurassic members of the ammonite superfamily Stephanoceratidae, assigned to the families Macrocephalitidae Buckman emend., **EUCYCLOCERATIDAE** (p. 203), Pachyceratidae Buckman emend., **MAYAITIDAE** (p. 222), and Reineckeidae Hyatt emend. In discussion of families, genera, and species many new names are given, new assignments are made for India and for other parts of the world. Names in the following list are for India unless other country is given. *Macrocephalites* **leei*** (p. 169); *M.* **steinmanni** (p. 170); **INDOCEPHALITES** (p. 171); type *I.* **kheraensis*** (p. 184); *Kamptokephalites* Buckman emend.; *K.* **bedfordensis** (p. 172); *K.* **maconnensis** (p. 172); *K.* **subpila** (p. 173); *K.* **hudlestoni** (*Macrocephalites h.* Blake) (p. 172) and *K.* **terebratus** (*Macrocephalites t.* Phillips) (p. 172), England; *Dolikephalites* **subcompressum** (*Stephanoceras s.* Waagen) (p. 173); *D.* **gracilis** (p. 173), Italy; *Nothocephalites* **semilaevis*** (*Stephanoceras s.* Waagen) (p. 174), *Kamptokephalites* **subkamptus** (p. 174), New Guinea; **ARCTOCEPHALITES** (p. 174), type *Ammonites ishmae arcticus* Newton, Franz Josef Land; *A.* **pompeckji** (*Macrocephalites p.* Sokolov) (p. 174), Russia; *Macrocephaliceras* **polyptychum** (p. 174), France; *Indocephalites* **gerthi** (*Macrocephalites diadematus* Gerth) (p. 175), Argentina; **EURYCEPHALITES** (p. 175), type *Macrocephalites vergarensis* Burckhardt (p. 175), Argentina; *E.* **eurystoma** (*Macrocephalites e.* Stehn) (p. 175), Argentina; **EPICEPHA-**

LITES (p. 175), type *Macrocephalites epigonus* Burckhardt, Mexico; **XENOCEPHALITES** (p. 175), type *Macrocephalites neuquensis* Stehn, Argentina; *X.* **extremus** (*Macrocephalites e.* Stehn) (p. 175), Argentina; *Macrocephalites* **triangularis*** (p. 180); *Indocephalites* **transitorius*** (p. 183); *I.* **chrysoolithicus*** (*Stephanoceras c.* Waagen) (p. 186); *I.* **diadematus*** (*Stephanoceras d.*) (p. 188); *I.* **indicus*** (p. 189); *I.* **gibbosus*** (p. 190); *I.* **sphaeroidalis*** (p. 191); *Pleurocephalites* **habyensis*** (p. 192); *P.* **elephantinus*** (*Ammonites e.* Sowerby) (p. 194); *Kamptokephalites* **magnumbilicatus*** (*Stephanoceras m.* Waagen) (p. 195); *K.* **dimerus*** (*Stephanoceras dimerum* Waagen) (p. 197); *K.* **lamellosus*** (*Ammonites l.* Sowerby) (p. 198); *K. l.* **aureus*** (p. 200), *K.* **etheridgei*** (p. 200), New Guinea; *Subkossmatia* **flemingi*** (p. 205); **SIVAJICERAS** (p. 205), type *Ammonites fissus* Sowerby; **IDIOCYCLOCERAS** (p. 205), type *I.* **perisphinctoides*** (p. 215); **NOTHOCEPHALITES** (p. 205), type *N.* **asaphus*** (p. 208); *N.* **mondegoensis*** (p. 206), Portugal; *Eucycloceras* **intermedium** (*Macrocephalites bifurcatum* G. Boehm, part) (p. 206), New Guinea; *Idiocycloceras* **bifurcatum** (*Macrocephalites b.* G. Boehm, part) (p. 206), *Nothocephalites* **paradoxus*** (p. 207), Madagascar; *N.* **semilaevis*** Waagen (p. 209); *Eucycloceras* **pilgrimi*** (p. 209); *E.* **intermedium** (*Macrocephalites keeuwensis* Boehm, pars) (p. 210); *Dolikephalites* **flexuosus*** (p. 210), New Guinea; *Subkossmatia* **obscura*** (p. 211); *S.* **coggin-browni*** (p. 212); *S.* **discoidea*** (p. 213); *S.* **ramosa*** (p. 214); *Idiocycloceras* **singulare*** (*Stephanoceras fissum* Waagen) (p. 216); *I.* **dubium*** (p. 217), *Erymnoceras* **dorotheae*** (p. 220), *Pachyceras indicum**; *P.* **distinctum*** (p. 222); *Mayaites* Spath emend.; **EPIMAYITES** (p. 223), type *Stephanoceras transiens** Waagen; *E.* **tenuicostatus** (*Macrocephalites palmarum* var. *tenuicostata* G. Boehm) (p. 223), *E.* **metroxyloni** (*Macrocephalites m.* G. Boehm) (p. 223), *E.* **batavoindicus** (*Macrocephalites b.* G. Boehm) (p. 223), *E.* **rotangi** (*Macrocephalites r.* G. Boehm) (p. 223), *E.* **palmarum** (*Macrocephalites p.* G. Boehm, part) (p. 223), *E.* **sublemoini** (*Macrocephalites palmarum* G. Boehm, part) (p. 223) and *E.* **sinuatus** (*Macrocephalites p.* var. *alpha* G. Boehm, part) (p. 224), New Guinea; *Mayaites* **rotundus*** (p. 227); *M.* **jumarensis*** (p. 228); *M.* **obesus*** (p. 228); *M.* **subkobyi*** (p. 229); *M.* **smeei*** (p. 230); *M.* **radiatus*** (p. 231); *Epimayaites* **polyphemus** (*Stephanoceras p.* Waagen) (p. 233); *E.* **lemoini*** (*Stephanoceras maya* Waagen) (p. 234); *E.* **axonoides*** (p. 235); *E.* **subtumidus*** (*Stephanoceras subtumidum* Waagen) (p. 237); *E.* **pseudindicus*** (p. 237); *E.* **evolutus*** (p. 238); *E.* **excentricus*** (p. 239), *E.* **transiens** (*Stephanoceras t.* Waagen) (p. 240); *E.* **lautus*** (p. 242); *E.* **falcoides*** (p. 242); *E.* **patella*** (p. 243); *Dhosaites* **elephantoides*** (*Stephanoceras elephantinum* Waagen, part) (p. 244); *D.* **otoitoides*** (p. 245); *D.* **primus*** (p. 245); **PARYPHOCERAS** (p. 247), type not designated; *P.* **rugosum*** (p. 247); *P.* **badiense*** (p. 248); *P.* **stephanoides** (*Stephanoceras fissum* Waagen, part) (p. 248); **PROGRAYICERAS** (p. 250), type *P.* **grayi** (*Stephanoceras nepalense* Waagen) (p. 250), *P.* **traumanense*** (p. 251), **PSEUDOSTRENOCERAS** (p. 253), type *Parkinsonia hystricoides* Rollier, France; **HEMIGARANTIA** (p. 253), type *Ammonites julii* d'Orb., France, **PSEUDOPLETOCERAS** (p. 255), type *Ammonites chauvinianus* d'Orb., France, **EPIMORPHOCERAS** (p. 257), type *Perisphinctes decorus* Waagen; *Reineckeia* **tyranniformis*** (p. 260); *R.* **smithi*** (p. 263); *R.* **ravana*** (p. 264); *Kellawaysites* **oxyptychoides*** (p. 266); *Reineckeites waageni* v. **regalis*** (p. 269); *Collotia* **drapaudi*** (p. 273); *C.* **kachhensis*** (p. 274); *C.* ? (*Reineckeia*) **octagona*** (p. 276). Figured and named on plate but not noted in text: *Prososphinctoides* **manialensis*** (pl. 42).—*J. B. Reeside, Jr.*

14633. TAKI, IWAO. Some ecological observations on Lymnaea (Radix) japonica Jay. VI. Résumé. [In Japanese, with English summary.] *The Venus* [*Japan*] 2(6): 278-294. 4 fig. 1931.—Observations on the copulation, egg laying, egg mass, feeding habits, and enemies. The most formidable enemy is the larva of *Hydrophilus acuminatus**, which crushes the columella of the body whorl and pulls the entire soft part of *Lymnaea* out of the shell, to serve as food.

14634. TOLMER, L. Essai sur la répartition géographique du genre Polycera Cuv. 1817 (Mollusque Nudibranche); et des trois espèces P. quadrilineata Müller, P. lessonii d'Orbigny, P. ocellata Alder et Hancock. *Bull. Soc. Linn. Normandie* 1: Trav. Orig. 30-38. Map. 1928 (1929).—The distribution of the 3 spp. is mapped. Bibliography of 32 titles.

14635. VINCENT, ÉMILE. Mollusques des couches à Cyrènes (Paléocène du Limbourg). (Mémoire posthume.) *Mém. Mus. Roy. Hist. Nat. Belgique* No. 43. 9-43. 7 pl. 1930.—This paper gives detailed description of a Paleocene section found in a mining shaft near Limbourg, Belgium. The fauna indicates brackish water conditions of deposition. Thirty-five spp. of mollusks are listed and described, including: *Arca* (*Barbatia*) **limburgica*** (p. 17); *Ostrea* (*Alectryonia*) **taxandrica*** (p. 19); *Diplodonta* (*Felaniella*) **eysdenensis*** (p. 20); *Corbicula* (*Loxoptychodon*) **taxandrica*** (p. 22); *Corbula* **rensoni*** (p. 26); *Jouannetia* **taxandrica*** (p. 28); *Teredo* **eysdenensis*** (p. 28); *Neritina* **disparilis*** (p. 29); *Bithynella* **eysdenensis*** (p. 31); *Natica* **eysdenensis*** (p. 31); *Melania* **limburgica*** (p. 32); *M.* (*Campylostylus*) **taxandrica*** (p. 34); *Aurelianella* **eysdenensis*** (p. 36); *Siphonalia* **aestuarina*** (p. 38); *Murex* (*Poireria*) **disparatus*** (p. 39); *Planorbis* (*Hippeutis*) **eysdenensis*** (p. 40); *Traliopsis* **belgica*** (p. 42).—*B. L. Clark.*

J. Rathbun.*

14644. **COTT, HUGH B. The Zoological Society's expedition to the Zambesi, 1927: No. 2. Observations on the natural history of the land-crab Sesarma meinerti, from Beira, with special reference to the theory of warning colours.** *Proc. Zool. Soc. London* 1929(4) : 679-692. 1 col. pl., 4 fig. 1929.—An account of the habits of *S. meinerti* found at Beira, East Africa, living on dry ground near mangrove swamps. This species has largely adopted terrestrial habits and the author gives some account of the structure and mechanisms which enable it to respire in air or in a minimum amount of water. A colored drawing of the species is given and evidence brought forward to show that the brilliant colors have a warning (aposematic) function. The vivid color, aggressive behavior and power of self-defence, tough physique, powers of regeneration, and relative freedom from persecution by enemies all point to this conclusion. The warning coloration is correlated with the exigencies of a more or less terrestrial mode of life and its origin and development are to be explained by the operation of natural selection.—*W. M. Tattersall.*

14645. **COTT, HUGH B. The Zoological Society's expedition to the Zambesi, 1927: No. 3. Observations on the natural history of the racing-crab Ocypoda ceratophthalma from Beira.** *Proc. Zool. Soc. London* 1929(4) : 755-765. 1 pl., 1 fig. 1929.—An account of the habits of *O. ceratophthalma* found at Beira, East Africa. The fossorial habits of the species are described, including the method of digging its burrow, the structure of the burrows and the special structural modifications to a fossorial habit. Some account is given of the enemies of the species, which are chiefly birds of prey, and the protective value of its cryptic coloration by day. The crabs are scavengers, and, though often seen abroad by day, are essentially nocturnal in habits. Notes are added on stridulation and on its cursorial habits. The crabs can travel over the loose sand at a speed of at least 10 miles per hr., and the pointed extremities and depressed shape of the dactyli of the walking legs are regarded as cursorial adaptations. The young are precocious as regards speed and sight, their legs and eyes attaining a high development at a very early age.—*W. M. Tattersall.*

14646. **[DEKSBACH, N. K.] ДЕКСБАХ, Н. К. Cladocera Кавказа и Северной Персии. [Cladocera of the Caucasus and northern Persia.]** [German summary.] Работы Северо-Кавказской Гидробиологической Станции (*Trav. Sta. Biol. Caucase du Nord*) 3(1/3) : 63-79. 1930.—Previous work on the Cladocera of this region is reviewed, 26 papers being listed. The material of the present study was obtained chiefly in small, shallow bodies of water, and supplements the previous material obtained mainly from lakes. It contains 22 spp. from the Caucasus and 7 from Persia. Of the 50 spp. and vars. recorded so far from the Caucasus, 23 play a leading rôle; a table compares their distribution in the Caucasus, the Carpathians, the Tatra, the Alps, and the mts. of N. Sweden. The Caucasian spp. include the following elements: cosmopolitan, endemic, those of eastern origin, and southern spp. Arctic forms and glacial relicts are lacking. Vertical distribution of the spp. is shown in a table. *Chydorus sphaericus* and *Alona quadrangularis* reach a height of 3000 m. *Moina rectirostris,* in pools at altitudes of 580-1870 m., is "polycyclic." *Daphnia pulex,* in pools at 610-1424 m., is "dicyclic." In a supplement the list of Caucasian spp. and vars. is increased to 88.—*From author's summary.*

14647. **DOLLFUS, ROBERT PH. Un hôte nouveau pour Sarcotaces verrucosus Olsson 1872 (Copepoda paras.).** *Bull. Mus. Nation. Hist. Nat. Paris* 34(5) : 341-345. 3 fig. 1928.—*S. verrucosus* ♀* is recorded as a parasite of *Iridio radiatus** in Martinique.

14648. **FAGE, LOUIS. Biospeologica. LVI. Campagne spéologique de C. Bolivar et R. Jeannel dans l'Amérique du Nord (1928). 5. Crustacés Amphipodes et Décapodes.** *Arch. Zool. Exp. et Gén.* 71(3) : 361-374. 21 fig. 1931.—Amphipoda: *Eucrangonyx packardi* was found in Don-

nelson's and Marengo caves, Indiana. Decapoda: Atylidae: *Palaemonias ganteri** was again found in Mammoth Cave, Kentucky, and is fully redescribed. Potamobiidae: *Cambarus pellucidus* was taken in Donnelson's Cave, Indiana; Mammoth and Horse Cave, Kentucky; and *C. bartoni tenebrosus* in Donnelson's and Marengo caves.

14649. GORDON, ISABELLA. African freshwater prawns of the species Caridina nilotica (Roux), with special reference to the Nile basin. *Proc. Zool. Soc. London* 1930(1): 33-50. 13 fig. 1930.—A detailed study of over 1000 specimens of *C. nilotica* from various east African localities extending from Egypt to Natal, with special reference to the variation of the telson, thoracic appendages, and rostrum. The results show that all over east Africa there is a vast assemblage of slight local deviations from the type form (*C. nilotica typica*), from the lower Nile. In each of the 2 large lakes, Victoria and Albert, there is a shore form, and an open water form which may be regarded as a lacustrine modification of the shore form.—*W. M. Tattersall.*

14650. GRAVIER, CH. Sur un Crustacé Stomatopode rare, le Gonodactylus guerinii White. *Bull. Mus. Nation. Hist. Nat. Paris* 34(5): 337-340. 3 fig. 1928.—A record of the 4th specimen known of *G. guerinii**, taken in the Marquesas Isls.

14665. PIROZHNIKOV, P. L. Zur Gammaridenfauna des Jenissej-Stromes. *Internat. Rev. Ges. Hydrobiol. u. Hydrograph.* 25(5/6): 373-380. 1 fig. 1931.—Notes on 9 spp. in Haustoriidae, Oedicerotidae, and Gammaridae.

14666. SCIACCHITANO, IGINIO. Copepodi raccolti dalla R. Nave "Ammiraglio Magnaghi." Nota preliminare. [Copepods taken by the ship, "Ammiraglio Magnaghi."] *Boll. Zool. Unione Zool. Italiana* 1(4): 149-151. 1930.—*Euchaeta* arabica ♂ (p. 149), *Xanthocalanus* gigas ♀ (p. 150) and *Amallophora* cristata (p. 150), all from the Gulf of Aden.

14667. TORELLI, BEATRICE. Sferomidi raccolti in Sardegna dal Prof. Achille Costa. [Sardinian sphaeromids collected by A. Costa.] *Ann. Mus. Zool. R. Univ. Napoli* 6(3): 1-5. 1 fig. 1929.—Three exceptionally large *Cymodoce spinosa* Risso, 2 ♂♂ and 1 ♀ of *C. emarginata* Leach, and 3 *Sphaeroma ephippium** Costa. The ♀ of *C. emarginata* is described for the first time and distinguished from the ♀ of *C. truncata.* Description and figure are supplied for *S. ephippium.* This species is not confined to pools as Costa supposed.—*B. Torelli* (*transl. by H. L. and C. H. Blake*).

14668. TORELLI, BEATRICE. Cymodoce erythraea Nobili e Cymodoce dellavallei Torelli. *Boll. Soc. Naturalisti Napoli* 41: 165-168. 6 fig. 1929(1930).—*C. erythraea* Nobili (=*C. dellavallei* Torelli) ♀ described.—*B. Torelli* (*transl. by C. H. Blake*).

14669. ULRICH, E. O. Ordovician trilobites of the family Telephidae and concerned stratigraphic correlations. *Proc. U. S. Nation. Mus.* 76(21): 1-101. 8 pl. 1929(1930).—Review of previous literature on the genus *Telephus,* with discussion of its systematic position and relationship, also a revised description. *Telephus, Glaphurus,* and the new genus *Glaphurina* are placed in Telephidae, and are thought to be related to *Irvingella* and *Chariocephalus* of the late Cambrian and early Ozarkian periods; these are also referred to the Telephidae, and the group is thought to have originated in the Arctic province. Critical notes on 6 European species, previously known, and descriptions of new spp., as follows: *T.* haddingi* (p. 12) and *T.* jamtlandicus* (p. 13), Ogygiocaris shale, Jamtland, Sweden; *T.* linnarssoni* (p. 15), Leptaena limestone, Sweden; type in Geol. Surv. Mus. [Stockholm]; *T.* reedi* (p. 19), Whitehouse Group, Scotland. Critical notes on the American spp. *T. americanus**, *T. gelasinosus**, and *T. troedssoni** and descriptions of new spp. as follows: *T.* mysticensis* and var. simulator* (p. 22), from limestone boulder, presumably Blount, or Chazyan age, Quebec; *T.* bicornis*

(p. 23), Whitesburg limestone, Virginia; *T.* **latus*** (p. 26), found only in limy basal Athens shale, Virginia; *T.* **pustulatus*** (p. 28), Whitesburg limestone, Virginia; *T.* **spiniferus*** (p. 29), limy basal Athens shale, Virginia; *T. s.* var. **calhounensis*** (p. 30), Athens shale, Tennessee; *T.* **sinuatus*** (p. 30), Whitesburg limestone, Virginia; *T.* **bipunctatus*** (p. 31), Whitesburg limestone, Virginia, Tennessee, Alabama; *T.* **impunctatus*** (p. 33), and *T.* **prattensis*** (p. 34), Whitesburg limestone, Tennessee and Alabama; *T.* **tellicoensis*** (p. 35), *T.* **transversus*** (p. 37) and *T.* **hircinus*** (p. 38), Tellico formation, Tennessee; *T.* **bilunatus*** (p. 39), Whitesburg limestone, Tennessee; *T.* **buttsi*** (p. 40), Athens shale, Alabama; *Glaphurus pustulatus**, emended descr.; *G.* **latior*** (p. 44), Whitesburg limestone, Virginia (type), and Alabama; **GLAPHURINA** (p. 44), type *G.* **lamottensis*** (p. 45), basal bed of Up. Chazyan, Vermont; *G.* **brevicula*** (p. 46), Holston limestone, Virginia; *G.* **falcifera*** (p. 46), Lower Chazyan, Tennessee. Types in U. S. Nat. Mus. unless otherwise stated. Stratigraphic and geographic range of the family, also correlation of formations in N. America and Europe, are discussed. The forms described are confined to Middle and Up. Chazyan age. The fauna is found only in the eastern portion of the Appalachian Valley (Virginia, Tennessee, and Alabama), in the extreme Up. Chazyan of the Champlain and St. Lawrence Valleys, and in formations in Britain, Norway, Sweden, and the Baltic region, which are considered equivalent in age. The distribution indicates a mid-Atlantic origin for the fauna. A correlation table, showing author's conception of the stratigraphic relations, is included.—*J. Bridge.*

14670. [BAROVSKIĬ, V. V.] БАРОВСКИЙ, В. В. К познанию энтомофауны озерной области. II. [Insect fauna of the lake region (Finland and adjacent territory). 2.] Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 23(1/2): 143-151. 1929.—Locality records for 89 forms of Coleoptera, 59 Hymenoptera, 16 Hemiptera-Heteroptera, and 1 Trichoptera, including many new records for the region. [Hymenoptera] *Nisson dimidiatus* ab. **nigrina** (p. 148), prov. Leningrad.

14671. **BURKILL, H. J. Plant galls section. Report for 1930.** *London Naturalist* 1930: 19-23. 1931.—A list for England, including Coleoptera, Cynipidae, Cecidomyidae, Muscidae, Psyllidae, Aphididae, Eriophyidae, and Nematoda.

14672. **COLE, A. C. Jr. Typha insects and their parasites.** *Ent. News* 42(1): 6-11; (2): 35-39. 1931.—Studies on the insects of *Typha latifolia* and *T. angustifolia*, principally at Monroe, Michigan, on *T. latifolia*. The species cause injury to the part of the plant mentioned after each name, and are parasitized as indicated. *Arsilonche albovenosa* [Lepidoptera], on leaves, parasitized by Blacus sp. and *Microbracon* sp. [Braconidae], *Rogas stigmator* [Ichneumonoidea], *Exorista larvarum* [Diptera], and *Macrocentrus ancylivora* and *Pimpla inquisitoriella* [Ichneumonoidea]; *Apatela oblinita* [Lepidoptera], on leaves, parasitized by *Sceliphron caementarium* and *Casinaria genuina; Endothaenia hebesana* [Lepidoptera], on seeds, parasitized by *Microbracon* sp.; *Lymnaecia phragmitella* [Lepidoptera], on heads; *Coleophara* sp. [Lepid.], in dried stalks; *Nonagria oblonga* [Noctuidae], in stalks; *N. subflava*, on leaves; *Archanara subcarnea* [Lepidoptera], in stalks, parasitized by *Masicera senilis* and *Muscina stabulans* [Diptera]; *Bactra maiorina*, on heads; *Cacoecia rosaceana* [Lepidoptera], on stalks; *Archips obsoletana* [Lepidoptera], on heads; *Platychirus quadratus* [Diptera], on heads; *Calendra pertinax*, in stalk near the surface of the ground; *Mononychus vulpeculus* [Curculionidae], in heads; *Paria canella* v. *aterima*, in leaf-sheaths; *Notaris puncticollis* [Curculionidae], in stems. Larvae of *Chaetopsis aenea* [Diptera], in lepidopterous burrows; larvae of *Macrosargus clavis*, on leaves, parasitized by *Diaulinus pulchripes* [Chalcidoidea] and *Tumidiscapus* sp. [Braconidae]; *Drosophila* sp., *Elachiptera nigriceps*, and *Corodonta dorsalis* [Diptera], reared from stalks; larvae of *Aphiochaeta chaetoneura*, in a tunnel of *Archanara subcarnea*; larvae of *Eurytoma* bicolor, in dry, overwintered stem galls; *Ischnorhynchus resedae* [Hemiptera] nymphs, feeding on moist petioles; 7 spp. of aphids recorded; eggs of *Conocephalus* sp. [Orthoptera], in stalk, parasitized by *Macroteleia* sp. and *Tumidiscapus* sp. [Chalcidoidea]; *Thripsaphis ballii* [Hemiptera], collected from moist petioles. A bibliography of 13 references is appended.

14673. **COSTA LIMA, A. da. Supplemento ao 2° catalogo systematico dos insectos que vivem nas plantas do Brasil e ensaio de bibliographia entomologica brasileira.** [Supplement to the 2nd systematic catalog of insects on Brazilian plants, with entomological bibliography.] *O Campo* [*Rio de Janeiro*] 1(9): 28-31. 1930.—Lists covering Fam. Hesperiidae and suborder Heterocera Fam. Castniidae (Lepidoptera) through Fam. Bostrichidae (Coleoptera).

14674. **CRAMPTON, G. C. A claim for priority in dividing pterygotan insects into two sections on the basis of the position of the wings in repose, with remarks on the relationships of the insect orders.** *Ent. News* 42(5): 130-136. 1931.—Discusses the synonymy of superordinal groups, especially of the Archipterygota Crampton 1924 (=Palaeoptera Martynov 1924, not the order Palaeoptera Crampton 1915), applied to the insects which hold the wings outstretched; and Neoptherygota Crampton (=Neoptera Martynov), applied to the insects which fold the wings along the top of the abdomen when in repose. Other questions of priority between the author and Martynov are discussed.

14675. **CRAMPTON, G. C. The terminal abdominal structures of female insects compared throughout the orders from the standpoint of phylogeny.** *Jour. New York Ent. Soc.* 37(4): 453-496. 8 pl. 1929.—The present paper coordinates the conclusions on the interrelationships of the orders drawn from earlier critical studies of other

parts of the insect anatomy. The primitive structure from which the ♀ abdomen is derived in the hypothetical protohexapod is depicted as having the limbs of the 8th, 9th, and 10th abdominal segments biramous as in Crustacea, composed of a basal portion or protopodite, an outer branch or exopodite, and an inner branch or endopodite. In the course of modifications the protopodite of the 8th abdominal limb becomes first a coxite and then a basivalvula, while its exopodite becomes a stylus and its endopodite a ventral ovipositor valve. The protopodite of the 9th abdominal limb becomes first a coxite and then a dorsal ovipositor valve; its exopodite becomes a stylus and its endopodite an inner ovipositor valve. The protopodite of the 10th abdominal limb is homologous with a coxite and is to become a paraproct, while its exopodite becomes a cercus and its endopodite a so-called "paraprocess." The writer has changed his viewpoint from earlier publications wherein he regarded the cerci as derived from the endopodites. The 11th tergite in the primitive forms bears a terminal appendage or "telite," which becomes multiarticulate in *Machilis*. *Grylloblatta** and *Rhipipteryx** represent very nearly the typical orthopteroid* type. *Machilis** is one of the nearest living representatives of the primitive Protohexapoda, from which the living orders are derived. The multiarticulate telofilum borne on the end of the suranale and the multiarticulate cerci borne at the tips of the paraprocts of *Machilis* clearly lead to the types of structures in the pterygote Ephemerida*; while the stylus-bearing, valve-like coxite of *Machilis* is clearly the prototype of the stylus-bearing, coxite-like, dorsal valve of the ovipositor of the Odonata* which are the most primitive Pterygota having this type of ovipositor. The Lepismatidae* are apparently the nearest living representatives of the types ancestral to the Pterygota. The terminal segments of the Japygidae* are so extremely similar to those of the Campodeidae* that there cannot be any doubt that they belong to one order, Dicellura. The closest relatives to the Protura among the Apterygota are the Collembola*. The closest relatives of the Plecoptera* are the Embiidae*. The similarity in terminal segments of these two orders and Orthoptera* indicates common ancestry. The Blattidae*, Mantidae*, and Isoptera*, form a compact group of orthopteroid insects. The Dermaptera* show affinity to this group on one hand and to true Orthoptera (Saltatoria*) and Phasmidae* on the other hand, with closest affinity to the latter. *Hemimerus** belongs truly to the Dermaptera and does not merit an ordinal rank. Dermaptera (=Diploglossata). *Grylloblatta** belongs to the true Orthoptera. The Zoraptera* are primitive Psocoptera. The Mallophaga* are evidently descended from psocoid ancestors. It is probable that the ancestors of the Anoplura* were closely allied to the mallophagoid ancestors. The Thysanoptera* present puzzling features showing affinities to several groups, but are quite closely related to the Hemiptera. *Eugereon* is evidently of palaeodictyopteroid type and has no affinities with the ancestors of the Hemiptera. The occurrence of long orthopteroid cerci in sawflies* suggests a protorthopteroid ancestry for the Hymenoptera*. The Coleoptera* are not very closely related either to Neuroptera* or Hymenoptera* but doubtless represent an early offshoot from the protorthopteroid ancestors of the Holometabola. The Mecoptera* are evidently descended from neuropteroid ancestors and are in turn the ancestors of the Diptera*, Trichoptera*, and Lepidoptera*. The Siphonaptera* are a baffling group; they cannot be descended from the Diptera. The terminal abdominal structures do not offer any valuable clues as to the affinities of the fleas. The writer closes with a table of 28 recent orders, and a bibliography of 56 references. The terminal segments of most of the orders are illustrated.

14676. GUNDER, J. D. A new insect camera of compact design. *Canadian Ent.* 62(10): 215. 1 pl. 1930.

14677. HEMMING, A. F., et al. [Notes and exhibition of specimens.] *Proc. Ent. Soc. London* 4(1): 1-68. 2 pl. (1 col.), 6 fig. 1929.—A. F. Hemming: [Lepidoptera] *Carcharodus dravira** Moore is distinct from *C. orientalis** Rev. (genitalia described and figured); *Polyommatus loewii* ssp. **lockharti** (p. 3), Transjordania, *P. l. l.* f. **margarita** (p. 4), Transjordania, and *P. l.* **antilibanotica** (p. 4), types in author's coll. [H. ST. J. K.] DONISTHORPE reports *Atomaria morio* [Coleoptera] new to Britain (from jackdaw's nest). R. STEWART MacDOUGALL reports *Eccoptogaster ratzeburghi* [Scolytidae] on birch in Scotland, the first finding in Britain in 67 years. F. C. FRASER reports a pair of *Danaida limniace* in copula from Malabar with the ♂ dead. O. W. RICHARDS suggests that the ♂ was killed by a spider. J. E. M. MELLOR (p. 8), submits *Spalgis lemolea* [Lepidoptera], whose larvae are active enemies of an *Icerya* [Coccidae] on a cycad in Zanzibar; ♂♂ of the black and red *Megachile combusta* [Apidae] are reported chasing ♂♂ of *Acraea insignis* f. *siginna* with similar colors [Lepidoptera]. E. STEP reports *Cynips kollari* galls on oak opened by blue-tits [*Parus caeruleus obscurus*]. HANITSCH describes the ♂ of *Ischnoptera pitmani* [Blattidae] from Uganda. H. M. PENDLEBURY describes the evening flight of *Milionia pyrozonis* [Lepidoptera] on Kedah Peak. F. M. S. V. G. L. VAN SOMEREN (p. 15) submits a specimen of *Papilio dardanus* f. cenea [Papilionidae] from Nairobi which had reverted to the ancestral tailed type due to mechanical shock experienced by the larva. J. E. M. MELLOR reports dragonflies (including *Brachythemis*) eating *Glossina palpalis* flies in Lake Victoria. E. B. POULTON discussed the Uvarov theory of locust migration, suggesting that there was probably a significant relationship between the conspicuous coloration and the gregarious habit of the migratory locusts [*Locusta migratoria*]. Certain migrating butterflies, such as *Belenois mesentina*, pair and oviposit during migrations, and others, such as *Libythea laius* and *L. labdaca*, have these functions delayed as in the migrating Acrididae. B. P. UVAROV states that migration of locusts is most closely connected with the rate of development of the sexual products. [J. C. F.] FRYER reports that in Ceylon *Belenois mesentina, Ixias pyrene* and *Huphina nerissa* [Lepidoptera] are sexually mature when migrating and deposit eggs on the bushes of *Capparis pedunculosa*. *Papilio polytes* is also sexually mature during migration. The writer does not believe that larval crowding gave rise to the migratory instinct but rather that the later helped to prevent overcrowding. W. J. LUCAS exhibited examples of predaceous species and their prey: *Formica rufa* with *Geotrupes sylvaticus, Vespa vulgaris* with *Eurois prasina, Dysmachus trigonus* with *Tortrix viridana, Pyrrhosoma nymphula* with *Leuctra hippopus, Philodromus aureolus* with *Coenonympha pamphilus* and another with *Ammophila campestris*. W. C. SIMMONS reports on the habits of the larvae of *Papilio dardanus dardanus* in Uganda. V. G. L. VAN SOMEREN submits a specimen of *Cryptomima hampsoni* mimicking *Oneinella analis*. E. B. POULTON exhibited Asilidae with their prey: *Asilus* sp. with *Itaballia demophile demophile*, from Brazil; *Neoitamus cyanurus* with an anthomyid, and *Dioctria baumhaueri* with *Rhamphomyia* sp., from England. B. B. OSMASTON, writing from Naini Tal, Central Himalayas, describes the manner of attack upon man by *Pangonia longirostris* [Tabanidae]; they usually attack the legs. T. D. BROUGHTON gives corroboratory evidence on the biting of man. CYNTHIA LONGFIELD reports being bitten by *Tabanus bovinus*. A. F. HEMMING describes *Zegris eupheme* **uarda*** (p. 26), from Transjordania (type), and Palestine, type in author's coll., which may be distinguished from *Z. e. dyala**. K. JORDAN exhibited specimens of *Mus musculus* L. from Brazil with swellings behind the ears each containing an extended ♀ of *Tunga caecata* [Siphonaptera]; notes are given on the genus generally known as *Dermatophylus*. Communications by E. B. POULTON, C. N. BAKER, J. W. YERBURY, K. A. C. DOIG, H. STEVENS, RODNEY C. WOOD, and C. L. COLLENETTE deal with the

attack on butterflies by birds. H. CECIL KENWAY communicates field notes on the South African [Lepidoptera] *Euxanthe wakefieldi*, and 7 spp. of *Charaxes: C. varanes varanes* on *Schmidelia africana, C. candiope candiope* on *Croton sylvaticus, C. druceanus druceanus* on *Eugenia cordata* and *E. gerrardi, C. xiphares* ssp. kenwayi E. B. Poulton (p. 48), on *Buddleia salvifolia*, Transvaal, type in Hope coll. K. JORDAN exhibited specimens showing ♂ sexual characters in the Anthribidae: *Ptychoderes nebulosus*, Phloeotragus hottentottus*, Meganthribus whiteheadi*, Mecocerus allectus*, Nemotrichus barbicornis**, and *Habrissus fasciatus**. G. TALBOT exhibited 6 cases of mimicry among Lepidoptera. H. M. EDELSTEN exhibited larvae of [Lepidoptera] *Chrysophanus dispar batavus* from England and presented the following report: Report of the Committee appointed by the Ent. Soc. of London for the Protection of British Lepidoptera (pp. 53-68, colored plate II). This report discusses the history of the species in England, its races, habits, and food plants. *Chrysophanus dispar dispar*, C. d. batavus**, and *C. d. rutilus** are illustrated in color.

14678. IMMS, A. D. A general textbook of entomology: including the anatomy, physiology, development and classification of insects. 2nd ed., rev. Illus. Methuen & Co., Ltd.: London, 1930. Pr. 36s.

14679. [KIZERITSKIĬ, V.] КИЗЕРИЦКИЙ, В. Энтомологические заметки. [Entomological notes.] Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 23(1/2): 115-123. 1929.—Data on distribution of 49 spp. of Coleoptera and on *Japyx solifugus* [Thysanura].

14680. KLOTS, ALEXANDER B. On the naming of individual variants in Lepidoptera. *Ent. News* 41(9): 298-302; (10): 324-328. 1930.—After discussing the tendencies in naming variants and especially J. D. Gunder's proposed classification of transition forms, the writer questions the effect on nomenclature and insists that scientific names should not be applied to any concept lower than subspecies and when so applied should have no standing in nomenclature.

14681. OMER-COOPER, J. Notes on the fresh-water fauna of southern Tunisia. *Entomologist* [*London*] 63 (810): 251-255. 1930.—Records in desert pools, including 11 Crustacea, 30 Coleoptera, and 14 Hemiptera.

14682. PRZIBRAM, HANS. Wachstumsmessungen an Sphodromantis bioculata Burm. IV. Zunahme der Facettengrösse und -Anzahl. *Zeitschr. Wiss. Biol. Abt. D. Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 122 (2): 289-299. 1930.—The facets of the compound eye increase from molt to molt in size and number differently in different hemimetabolous insects. The mantis, *S. bioculata*, in nymphal stages 1-6 and then again after stage 9 shows an increase of single facet lengths as 1 is to 1.26, that is, a doubling of corneal volume. In stages 6 to 9 the length increase is less, being about 1:1.414 for the 3 intervals, corresponding to a doubling of the outer surface of the eye. After the 10th molt the number of facets has doubled since the hatching of the larva. A comparison of the eye development in *Dixippus morosus, Oxycarenus hyalinipennis, Blatta orientalis*, and *Notonecta glauca* shows a prevalence of the doubling principle, which applies in some cases to the volume, in others to the surface, and sometimes to the number of component parts (facets), with various combinations of these relations at different stages of development in the same species.—*W. P. Hayes.*

14683. SMIRNOV, EUGEN, und A. N. ZHELOCHOVTSEV. Über den Einfluss verkürzter larvaler Ernährungszeit auf die morphologischen Charaktere von Drosophila funebris F. *Zeitschr. Wiss. Zool.* [*Leipzig*] 135 (1/2): 214-255. 26 fig. 1929.—A biometric study of 19 wing measurements of 36 ♀♀ from larvae which fed for 9 days, as contrasted with similar measurements of 96 ♀♀ from fully nourished (13 days feeding before pupation) larvae. The restricted feeding produced smaller flies, with the wing measurements reduced on the average about 12%. The distance between the points of union of the 2nd and 3rd longitudinal veins with the marginal vein showed the minimum reduction (5.2%); the length of the posterior cross vein, the maximum decrease (16.6%). The basal portion was reduced to greater degree than the distal. The average of the coefficients of variability of the test flies was about 2.5 times that for the controls. The restricted feeding increased all 171 coefficients of total correlation without exception, but reduced the range (0.554 to 0.994) over that of the control series (0.092 to 0.947). There is a definite direction of stronger and weaker correlation, so that the wing may be considered a vectorial field. The law of proximity in regard to total correlation has only secondary interest. Partial correlation (with constant wing length) is much weaker than the total, and is conditioned by topographical proximity. Coefficients of regression are higher as a rule in the experimental series. The results agree closely with those previously obtained for *Calliphora* (B. A. 2: entry 14751).—*A. H. Hersh.*

14684. SNODGRASS, R. E. How insects fly. *Smithsonian Inst. Ann. Rept. Board of Regents* 1929: 383-421. 25 fig. 1930.—Insects are the only animals with true wings, i.e., separate organs and not adaptations of other organs for flying. The origin of wings is unknown, but probably they arose from lateral thoracic extensions which served as gliders. Winged insects are divided into vibrators and flexors,—those which keep their wings extended in rest or fold them tip to tip, and those which fold them horizontally and over the abdomen. The first includes dragonflies and mayflies; the other, the remainder of insects (except butterflies). Wings consist of membranes supported by "veins," which are fundamentally similar in all groups. Articulation is simplest in the vibratory type; in flexion an additional mechanism for folding is required and hence a larger number of sclerites. In the first type there are 4 sets of wing muscles, and 5 sets in the flexion type. Wing movements embrace flight, or flexion and extension. Flight movements consist of upstroke, downstroke, forward movement, rearward movement, and partial rotation of the wings on their long axis producing a figure 8. Rotary movement occurs in swift-flying insects (bee, dragonfly, flies), up-and-down movement in slower fliers (grasshoppers and butterflies). The number of strokes varies from 8 to 300 per sec. Speed is high, and highest in hawk moths (Sphingidae), up to 15 m. per sec. Steering is accomplished by the wings themselves, not by abdominal and leg movements. Hovering, reversed, lateral, and circuitous flying are unexplained because of lack of present knowledge of static (equilibrial) and kinetic organs in insects. Blinded insects fly without difficulty.—*R. A. Muttkowski.*

14685. TALBOT, G. The naming of individual variants in Lepidoptera. *Ent. News* 42(3): 80-82. 1931.

14686. TASCHENBERG, ERNST. Die Insekten. In: Brehms Tierleben. Bd. 8. Herausgegeben von CARL W. NEUMANN. 644p. 72 pl. (8 col.) Philipp Reclam Jun.: Leipzig, 1929.—Neumann's work involves a complete revision of the earlier text. It deals with the natural history rather than with the morphology, development, or classification of the Insecta. Especial attention is given to the genera and species of Germany and to those of economic and popular interest, such as ants, bees, wasps, gall insects, leaf rollers, beetles, mosquitoes, flies, fleas, butterflies, the silkworm, ant lions, plant lice, cicadas, lice, termites, grasshoppers, crickets, and dragon flies. The illustrations are noteworthy for their composition and completeness.—*C. A. Kofoid.*

14689. WALKER, E. M. On the clypeus and labium of primitive insects. *Canadian Ent.* 63(4): 75-81. 1 pl.

1931.—The primitive clypeus is undivided, as in *Thermobia** [Thysanura]. The first indication of a division into ante- and postclypeus is the extension of the membranous area adjacent to the labral articulation as in *Forficula** [Dermaptera], *Embia** [Embioptera], *Parcoblatta* [Dictyoptera], and *Grylloblatta* [Notoptera]. Re-sclerotization of this membrane has given rise to a more definite anteclypeus separated from the postclypeus by a more or less definite fold or suture, as in *Gryllus** [Orthoptera] and *Libellula** [Odonata]. The primitive insect labium is divided into 2 median segments, the submentum and mentum. The submentum is primarily undivided as in *Thermobia**. The first indication of division is the extension of the membranous area adjacent to the mentum, as in *Machilis** [Prototthysanura]. Re-sclerotization of this membrane, or part of it, has given rise to a secondary submental sclerite, as in *Periplaneta** and *Gryllus**, and the Blattidae*. This part has commonly been called the mentum. The secondary nature of this sclerite is shown by its lack of muscular attachments, its absence in the Apterygota, and its tendency to become reunited with the primary submental sclerite and thus lose its identity. The submentum is probably homologous with the united cardines of the maxillae, to which possibly a part of the labial sternum is added. The "medilabium" of Crampton is merely a part of the articular membrane between mentum and submentum. The "gulamentum" is merely the submentum and in the absence of a definite gula it is impossible to recognize a gular region, either on the basis of "submento-mental" muscles or on the position of the posterior tentorial pits, which may or may not take part in the process of elongation to which the ventral parts of the head are subjected when prognathism develops.

The biology is briefly sketched.

14695. GRANDJEAN, F. Existence d'une vésicule externe ou d'un organe poreux sous-alaires dans plusieurs genres d'Oribatei. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(6): 406-409. 1 pl. 1929.—This organ is described and figured for *Achipteria nitens**, *Ceratozetes gracilis**, and *Oribatella quadricornuta**.

14696. LeVEQUE, NORMA. Mites of genus Dinogamasus (Dolaea) found in the abdominal pouch of African bees known as Mesotrichia or Koptorthosoma (Xylocopidae). *Amer. Mus. Novitates* 434. 1-19. 11 fig. 1930.—A list of 14 previously described species is given with references to the original descriptions. *Dinogamasus crassipes* Kramer (=*Dolaea maxima* Vitzthum; = *Greenia sjöstedti* Tragardh), and possibly *Dolaea schoutedeni* Oudemans is a synonym of *D. crassipes*. Seven spp. of the *Mesotrichia flavorufa* group are listed as hosts for *D. villosior* (Berlese). A key to spp. of the *D. braunsi* group is given including *D.* **acutus*** ♀ (p. 13), host *Mesotrichia luteola*, Belgian Congo; *D.* **brevihirtus*** ♀ (p. 13), host *M. cloti*, Belgian Congo; *D.* **cockerelli*** ♀ (p. 14), type from *M. incerta seychellensis*, Seychelles, Mahé, Indian Ocean, other specimens from *M. caffra*, Rikatla, Delagoa Bay; *D.* **inflatus*** ♀ (p. 14), host *M. aestuans*, Egypt; *D.* **heteraspis*** ♀ (p. 15), host *M. imitator*, Belgian Congo; *D.* **productus*** ♀ (p. 16), host *M. divisa*, Natal; *D.* **parvus*** ♀ (p. 16), host *M. codiani*, Lisala, Belgian Congo; *D.* **oudemansi*** ♀ (p. 18), host *M. stuhlmanni*, Rikatla, Delagoa Bay; *D.* **bequaerti** ♀ (p. 18), host *M. albifimbria*, Belgian Congo. Types of new spp. in Amer. Mus. Nat. Hist.—*J. W. Wilson*.

14697. Le VEQUE, NORMA. New species of Dinogamasus (Dolaea), symbiotic mites of carpenter bees from the Oriental tropics. *Amer. Mus. Novitates* 479. 14p. 4 pl. 1931.—Key to spp. of *Dinogamasus* including *D.* **kerrianus** (p. 1), Siam; *D.* **concinnus*** (p. 5), *D.* **similis** (p. 5) and *D.* **ramaleyi*** (p. 5), Philippines; *D.* **longipes*** (p. 7), Siam; *D.* **trihirtus*** (p. 8) and *D.* **macgregori*** (p. 8), Philippines; *D.* **octoconus*** (p. 11), Java (type) and Siam; *D.* **bakeri*** (p. 12), Singapore; *D.* **brevipes*** (p. 12), Szechwan, China. All are from species of *Mesotrichia*. Types in Amer. Mus. Nat. Hist.

14698. LUNDBLAD, O. Die Hydracarinen der Insel Bornholm. *Kgl. Danske Videnskab. Selskab. Biol. Meddel.* 8(7): 1-96. 9 pl. 1930.—Forty-four species of water mites were collected from 7 stagnant pools, and 16 fresh water stations. Descriptive notes are included, and *Lebertia* (*Hexalebertia*) *stigmatifera* v. **separata*** (p. 32) is described. Detailed notes on distribution, ecological conditions of the water, and abundance of individuals are also given.—*J. W. Wilson*.

14699. LUNDBLAD, O. Zur Kenntnis der wenig bekannten Hydracarine Acerus pistillifer var. stylatus Lundblad. *Zool. Anz.* 96(11/12): 292-298. 1931.—*Acercus pistillifer* v. *stylatus* ♂ and ♀ described in detail, from Sweden.

14700. McGREGOR, E. A. A new spinning mite attacking raspberry in Michigan. *Proc. Ent. Soc. Washington* 33(8): 193-194. 1 pl. 1931.—*Tetranychus* **mcdanieli*** (p. 193) and *Paratetranychus ilicis* attack raspberry in Michigan.

14701. MAGLIO, CARLO. Idracarini raccolti in Cirenaica dal Prof. E. Zavattari. [Acarina collected in Cyrenaica by Prof. Zavattari.] *Boll. Zool.* [*Naples*] 2(3): 111-113. 1931.—The specimens were all of *Hydryphantes acutus* Walt., previously reported from Spain and Morocco. This new locality indicates that it is probably a circum-Mediterranean sp.

14702. OUDEMANS, A. C. Notizen über Acari. 27. Reihe (Oribatidae). *Arch. Naturgesch. Abt. A* 91(8): 120-147. 36 fig. 1927.—Detailed studies of the history of the genus *Notaspis*, and of the synonymy and morphology of *N. coleoptratus*, *N. punctata**, *N. nitens**, *N. intermedia**, *N. patavinus**, and *N. italicus**.

14703. OUDEMANS, A. C. Aus P. Kramers Nachlass (Acari). *Arch. Naturgesch. Abt. A* 92(4): 99-119. 8 fig. 1926[1928].—*Trombidium* **pectinifer*** (p. 99), German

E. Africa; *T. tinctorium* L., notes; *Megisthanus* lamellicornium* (p. 101), "Kuri Isl." [Island in Chad Lake]; *M.* oblongus* (p. 104), locality not given; **STENOSTERNUM** (p. 107), near *Megisthanus* and *Antennophorus*, with *S.* bipilosum* (p. 107), E. Africa; *Megisthanus armiger* Berlese is considered referable to the new genus; *Dinogamasus* crassipes* (p. 112), Central Africa; *Lobocephalus* acuminatus* (p. 115), no locality given; *Euzercon* ovale* (p. 116), E. Africa.

14704. **SELLNICK, MAX.** Milben im Bernstein. *Bernstein-Forschungen (Amber Studies)* 2. 148-180. 39 fig. 1931.—Descriptions of mites found in Baltic amber. Oribatidae: *Pelops* punctulatus* (p. 151); *Galumna* diversa (p. 152); *G.* clavata* (p. 152); *Neoribates* borussicus* (p. 153); *Oribatella* mirabilis* (p. 153); *Tectoribates* parvus* (p. 154); *Sphaerozetes* primus* (p. 155); *Melanozetes mollicomus* form fossilis (p. 155); *M.* foderatus* (p. 155); *Chamobates* difficilis* (p. 156); *Protoribates* longipilis* (p. 157); *Scheloribates* areatus* (p. 158); *S.* setatus* (p. 159); *S.* apertus* (p. 159); *Oripoda* baltica* (p. 160); *Liebstadia* similiformis* (p. 161); *Eporibatula* pellucida* (p. 162); *Trhypochthonius* corniculatus* (p. 162); *T.* badiiformis (p. 163); *Scapheremaeus* undosus (*Mulvius u.* Selln.) (p. 164); *S.* acuminatus* (p. 164); *Micreremus* scrobiculatus* (p. 164); *M.* reticulatus* (p. 165); *Hermanniella* concamerata* (p. 166); *Tectocepheus* similis* (p. 168); *Carabodes* gerberi* (p. 168); *C.* dissonus* (p. 170); *C. coriaceus* f. fossilis (p. 170); *C. labyrinthicus* f. fossilis (p. 170); *Otocepheus* niger (p. 171); *O.* praesignis (p. 172); *Cultroribula* superba* (p. 172); *C.* lauta* (p. 173); *Licneremaeus* fritschi* (p. 173); *Caleremaeus* gleso* (p. 174); *Suctobelba subtrigonus* f. fossilis (p. 175); *Dameosoma* sucinum* (p. 175); *D. longilamellatum* f. fossilis (p. 176); *D.* medium* (p. 176); *D.* angustum* (p. 177); *Lucoppia* (?) simplex* (p. 177); *Oribotritia* translucida* (p. 179); *Damaeus* (?) gedanensis* (p. 179).

14705. **VIETS, KARL.** Über eine an Krebskiemen parasitierende Halacaride aus Australien. *Zool. Anzeiger* 96(5/6): 115-120. 6 fig. 1931.—Halacaridae: **ASTACOPSIPHAGINAE** (p. 116), n. subfam., type **ASTACOPSIPHAGUS** (p. 115), type *A.* parasiticus* (p. 115), parasite in the gills of *Astacopsis serratus* from southern Queensland; type in Australian Mus.

14706. **VITZTHUM, H.** Pneumonyssus stammeri, ein neuer Lungenparasit. *Zeitschr. Wiss. Biol. Abt. F, Zeitschr. Parasitenk.* 2(5): 595-615. 5 fig. 1930.—The article is introduced with a list of acarian parasites of the lungs of reptiles, birds and mammals. The parasites of monkey lungs are considered in detail: *Pneumonyssus simicola, P. griffithi, P. duttoni* and *Pneumotuber macaci. Pneumonyssus* stammeri ♀* (p. 606), parasite in lungs of a S. American *Lagothrix infumatus*. The phylogeny of the lung parasite genera is discussed. The genus *Pneumonyssus* is arranged with the mammalian lung parasite genus *Halarachne* in the Halarachnidae, with indications of derivation from the Laelapidae.

14707. **VITZTHUM, H.** Eine afrikanische Jacobsonia (Acari). *Zool. Anz.* 96(5/6): 153-159. 4 fig. 1931.—*Jacobsonia* tertia* (p. 153), Gabon, parasitic on a myriapod.

14708. **VITZTHUM, H.** Zwei neue deutsche Milben. *Zool. Anz.* 96(7/8): 187-192. 4 fig. 1931.—*Halolaelaps* holsaticus* (p. 187) and *Tyroglyphus* psenuli* (p. 190) (on *Psen atratus*), Germany.

H. Hatch.*

14715. BENICK, L. Ein Riesen-Stenus aus Neu-Guinea. *Neue Beitr. Syst. Insektenk.* 5(2/3): 32-33. 1931.—*Stenus* **gigas** ♀ (p. 32), type in Nat. Hist. Mus. Genoa.

14716. BERNHAUER, MAX. Neue Staphyliniden aus China von der Stötzner'schen Expedition. *Ent. Nachrichtenbl.* 5(1): 1-3. 1931.—*Paederus* **chinensis** (p. 1), *Othius* **stötzneri** (p. 1), *Philonthus* **emdeni** (p. 2), and *Staphylinus* (*Ocypus*) **sericeomicans** (p. 2), all from Sze-chwan. Types in Dresden State Mus.

14718. BORCHMANN, FR. Alleculidae y Meloidae. [Translated into Spanish by C. BRUCH.] *Rev. Soc. Ent. Argentina* 3(2): 85-100. 2 pl. 1930.—*Allecula* **pupillata** (p. 85); *A.* **procera** (p. 86); *A.* **bruchiana*** (p. 87); *A.* **sericeipes*** (p. 88); *A.* **collaris** ♂ (p. 88), Paraguay [type depository not given]; *A.* **exigua*** (p. 89); *Lobopoda* (?) **nana** ♂ (p. 90); *Epicauta* **nigripes*** (p. 91); *E.* **rutilifrons*** (p. 91); *E.* **curticollis*** (p. 92), Paraguay; *E.* **costipennis*** (p. 93); *E.* **bruchi*** (p. 93); *E.* **minute-punctata*** (p. 94); *E.* **langei*** (p. 94); *E.* **pluvialis*** (p. 95); *Spastica* **tristis** ♂ (p. 96), Brazil, type in author's coll.; *Nemognatha* **bilunulata** ♂ (p. 97); *Tetraonyx* **seminiger*** (p. 97); *Pseudomeloe* **flavomaculatus** (p. 98); *P.* **caligatus*** (p. 99); *P.* **unicolor*** (p. 99); *P.* **araneipes*** (p. 100). All from Argentina and types in coll. Bruch, unless otherwise stated.

14719. BORCHMANN, FRITZ. Neue Lagriiden aus Niederländisch-Indien. *Tijdschr. voor Ent.* 72(3/4): 187-196. 1929.—*Cerogia* **luchti** (p. 187), Sumatra; *C. quadraticollis*, first description of ♂; *Lagria* **drescheri** (p. 190) and *L.* **kannegieteri** (p. 191), Sumatra; *L.* **cimetaria** (p. 192), Batoe; *Heterogria* **javanica** (p. 193) and *Casnonidea* **drescheri** (p. 195), Java.

14720. BROWN, W. J. Coleoptera of the north shore of the Gulf of the St. Lawrence. *Canadian Ent.* 62(10): 231-237; (11): 239-246. 1930.—An insect survey from Trinity Bay to Bradore Bay in the Straits of Belle Isle. Collecting records on 4 Cicindelidae, 33 Carabidae, including *Curtonotus* **imperfectus** ♀ (p. 232), Quebec; 2 Haliplidae, 42 Dytiscidae, including *Coelambus* **quebecensis** (p. 234), Quebec, and *Hydroporus* **brumalis** (p. 235), Quebec; 7 Gyrinidae, 12 Hydrophilidae, 11 Silphidae, 22 Staphylinidae, 1 each in Ptiliidae, Scaphidiidae, Histeridae, Lycidae, Mordellidae, Pythidae, Dascillidae, Helodidae, Rhizophagidae, and Cucujidae; 2 each in Lampyridae and Cryptophagidae; 4 Cantharidae, 16 Elateridae, and 3 Buprestidae. *Limnius* **subarcticus** (p. 241), Quebec (Helmidae) 5 Byrrhidae, 3 Nitidulidae, 5 Lathridiidae, 4 Coccinellidae, 4 Melandryidae, 8 Scarabaeidae, including *Aphodius* **errans** (p. 243), Quebec (type), New Brunswick, Alberta, Brit. Columbia; 5 Cerambycidae, 6 Chrysomelidae, 13 Curculionidae, and 5 Scolytidae. Types in Canadian Nat. Coll.

14721. BRUCH, CARLOS. Tres interesantes coleópteros. *Rev. Soc. Ent. Argentina* 1(4): 15-22. 1 pl., 6 fig. 1927.—**CICINDISINI** (p. 17), new tribal name, established for *Cicindis horni** Bruch; *Burmeisteriellus mirabilis**, first description of ♀; *Drilocephalus pallidipennis* v. **brunnea** (p. 22), Argentina, type in author's coll.

14722. BRYANT, G. E. New species of African Spondylia (Megalopidae, Col.). *Ann. and Mag. Nat. Hist.* 7(42): 547-557. 5 pl. 1931.—*S.* **clytoides*** (p. 549), Rhodesia; *S.* **bicolor*** (p. 551), Tanganyika; *S.* **pubicollis*** (p. 553), Rhodesia; *S.* **lineata*** (p. 555), Uganda; *Poecilomorpha* **dollmani*** (p. 555), Rhodesia. Types in Brit. Mus. Key is given to the African spp. of *Spondylia*.

14723. BURGEON, L. Description d'une nouvelle espèce de Catascopus (Col. Carabidae) du Congo Belge. *Rev. Zool. et Bot. Africaines* 19(1): 123-124. 1930.—*C.* **uelensis** (p. 123), type in Congo Mus.

14724. CARTER, H. J. New Guinea and Australian Coleoptera. Notes and new species. *Proc. Linnean Soc. N. S. Wales* 55(5): 532-549. 13 fig. 1930.—*Stigmodera* (*Castiarina*) **apicenotata*** (p. 533), Queensland, type in S. Australian Mus.; *S.* **ariel*** (p. 533) and *S.* (*C.*) **bogania*** (p. 534), N. S. Wales, types in author's coll.; *S.* (*C.*) **dryadula*** (p. 535), New Guinea, type in S. Australian Mus.; *S.* (*C.*) **quadriplagiata*** (p. 535) and *S.* (*C.*) **mackayana*** (p. 536), Queensland, types in S. Australian Mus.; *Lyriocnrodes* **variabilis** (p. 537), Queensland, N. S. Wales; *Derispia coccinelloides* is not an Australian insect; *Pseudolyprops* **australiae*** (p. 538), N. Australia, type in Mus. of Div. Econ. Ent., Canberra; *Pteroneclacus* **wagneri** (p. 538), New Guinea, type in S. Australian Mus.; *Helaeus* **perlatus** (p. 539), W. Australia, and *Quosterrhis* **hackeri** (p. 539), S. Australia, types in author's coll.; **NEOTHECA** (p. 540) (Tenebrionidae, Cnodalonimae) type *N.* **fusca*** (p. 540), New Guinea, type in S. Australian Mus.; *Licinoma* **oblonga*** (p. 541), Queensland, and *L.* **tricolor** (p. 542), N. S. Wales, types in author's coll.; *Amarygmus* **insignis** (p. 542), New Guinea; *A.* **hossfeldi** (p. 543), New Guinea, type in S. Australian Mus.; *Chalcopterus* **nitidus** (p. 544), West Australia, type in Australian Museum; *Ebenolus* **serraticollis*** (p. 544), New Guinea, type in S. Australian Mus.; *E.* **papuensis** (*Allecula p.* Macl.; = *E. wollastoni* Blair) (p. 545); *E. p.* var. **anthracinus** (*E. wollastoni* var. *a.* Geb.) (p. 545); *E.* **aruensis*** (p. 545), Aru Is.; *Strongylium* **pusillum** (p. 545) and *S.* **wagneri*** (p. 546), New Guinea, types in S. Australian Mus.; *Zophophilus* Fairm. (= *Sphenothorax* Geb., *Teremenes* Cart.); *Coptocercus* **scripticollis*** (p. 548), Victoria, type in Hamburg Mus.; *Porithodes*, key to spp.; *P.* **pustulata** (p. 548), Queensland, type in author's coll.; *Dascillus* **oblongus** (p. 549), N. S. Wales, type in author's coll.

14725. CORPORAAL, J. B. Check-list of the Cleridae of Sumatra with their geographical distribution outside this island. (8th communication on Cleridae.) *Misc. Zool. Sumatrana* 51. 1-6. 1931.

14726. CROS, A. Le Sitaris solieri Pecchioli. Sa larve primaire. Étude biologique. *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 77-84. 1 pl. 1930.—*S. solieri* was taken ovipositing on rosemary, *Rosmarinus officinalis*, a large cluster of eggs. The first larva* is described; specimens were seen to attach themselves to hairs of a bee. Evidence is presented to indicate that the first larvae may hibernate as such.

14727. CROS, AUGUSTE. Zonabris silbermanni Chevrolat. Etude biologique. *Bull. Soc. Hist. Nat. Afrique Nord* 21(3): 36-42. 1930.—In examining lots of oothecae of *Dociostaurus maroccanus* from Algeria, numerous larvae of *Trichodes x-littera* were found and 3 hypnothecae of *Zonabris silbermanni*, also 2 2nd stage meloid larvae, presumably of the same species. The hypnothecae are described. This stage lasted through the winter. In April the hypnothecal skin was cast and a prepupal larva stage appeared, which after 25 days transformed into a pupa. The pupal stage lasts 31 days. The life history of this insect has previously been unknown.

14728. DEANE, CEDRIC. Trichopterygidae of Australia and Tasmania. Descriptions of six new genera and eleven new species. *Proc. Linnean Soc. N. S. Wales* 55(4): 477-487. 22 fig. 1930.—**PHILAGARICA** (p. 477), near *Nossidium*, type *P.* **agilis*** (p. 478), N. S. Wales, type in author's coll.; *P.* **pilosa** (p. 479), Tasmania, type in Lea coll.; **LEADUADICUS** (p. 480), compared with *Ptenidium*, type *L.* **tolerabilis*** (p. 480), N. S. Wales, type in Lea coll.; *L.* **imperialis*** (p. 480), Queensland, type in S. Australian Mus.; **ACHOSIA** (p. 481), allied to *Ptinella*, type *A.* **lanigera*** (p. 482), type in S. Australian Mus. and *A.* **femoralis*** (p. 482), type in Lea coll., both N. S. Wales; **EPOPTIA** (p. 482), near *Ptenidium*, type *E.* **rotunda*** (p. 483), Tasmania, type in S. Australian Mus.; *Trichopteryx* **australica*** (p. 483), Victoria, type in author's coll.; **COCHLIARION** (p. 484), compared with *Rodwayia*, type *C.* **victoriense*** (p. 485)

and *Rodwayia* **grandis*** (p. 485), Victoria, types in author's coll.; **CNEMADOXIA*** (p. 486), near *Ptiliodes*, type *C.* **okei*** (p. 487), Victoria, in nests of the ant *Amblyopone obscura*, type in author's coll.

14729. DONISTHORPE, HORACE. Coleoptera found in the "birch-bracket" fungus, Polyporus betulinus. *Ent. Record and Jour. Var.* 43(1): 14. 1931.—A list of some 30 spp. found in Windsor forest, England, including: *Cryptophagus dentatus* ab. **major.**

14730. EDMONDS, T. H. Cartodere separanda, Reitt., a species of Coleoptera new to Britain. *Ent. Rec. Jour. Var.* 42(11): 148-149. 1930.

14731. ELSTON, ALBERT H. Elateridae. Results of Dr. E. Mjöberg's Swedish Scientific Expedition to Australia 1910-1913. 50. *Arkiv. Zool.* [*Stockholm*] 22 A(1, Paper 1): 1-22. 1931.—List of spp. including: *Lacon* **recticollis** (p. 4) and *L.* **mjöbergi** (p. 5), Queensland, *L.* **reticulatus** (p. 6), N. W. Australia; *Glypheus* **sanguineus** (p. 8), Queensland; *Conoderus rufifrons* Cand. and *C. castaneipennis* Macleay, redescribed; *C.* **mentitus** (p. 13), N. W. Australia, *C.* **mjöbergi** (p. 13), Queensland; *Cardiophorus macleayi* Schwarz, emended description; *Paracardiophorus* **mjöbergi** (p. 16), and *P.* **jugulus** (p. 16), N. W. Australia; *P.* **attenuatipennis** (p. 17), Queensland; *Hapatesus pretiosus* Cand., comparative notes; *H. jugulatus* Cand., emended description; *H. hirtus* v. **minor** (p. 19), *Agonischius* **mjöbergi** (p. 20), and *A.* **laticornis** (p. 21), Queensland; *Ascesis* **testaceus** (p. 21), N. W. Australia. Types are in Stockholm Mus.

14732. GARDNER, J. C. M. The early stages of Niponius andrewesi, Lew. (Col. Hist.) *Bull. Ent. Res.* [*London*] 21(1): 15-18. 1 pl., 1 fig. 1930.—Biological notes and illustrated descriptions of full grown larva, prepupa, and pupa.

14733. HATCH, MELVILLE H., and A. I. ORTENBURGER. Records and new species of Coleoptera from Oklahoma. *Publ. Univ. Oklahoma Biol. Surv.* 2(1): 7-14. 1930.—An annotated list of 95 spp. previously recorded from and 59 spp. recently collected in the state, including *Bembidion* (*Odontium*) **weesi** (p. 11) and *Philonthus* **oklahomensis** (p. 12). Notes on *Omophron americanum iridescens* Csy. and *Acmaeodera neglecta* Fall. A key to 8 spp. of the *hepaticus* group of *Philonthus*.—*M. H. Hatch.*

14734. HATCH, MELVILLE H. The collection and preparation of Coleoptera. *Publ. Univ. Oklahoma Biol. Surv.* 2(1): 27-31. 1930.—Killing, nets, collecting, mounting, labeling, care of collection, and dealers are discussed, with bibliography.—*M. H. Hatch.*

14735. HOSCHECK, ARTHUR BARON. Beiträge zur Kenntnis der Buprestiden (Col.) III. *Mitteil. Zool. Mus. Berlin* 17(1): 133-164. 11 fig. 1931.—*Neopolycesta* **gebhardti*** (p. 134), Madagascar, type in Zool. Mus. Berlin; *Halecia* **superba*** (p. 135), Costa Rica, type in author's coll.; descriptive notes on *C. modesta**, *C. hustachei*, *C. diviana**, *C. celsa**; *Chrysobothris* **kuntzeni*** (p. 142), Mindanao [P. I.], type in Zool. Mus., Berlin; *C.* **facialis*** (p. 144), Costa Rica; *C.* **pseudinsularis** (p. 146), Jamaica, type in Zool. Mus., Berlin; *Actenodes heros* v. **picta** (p. 147), French Guiana; *Conognatha* **ovatula** (p. 148), Brazil, ♂ type in author's coll., ♀ type in Dresden Mus. f. Nat. u. Völkerkunde; *C. gracilis*, valid sp.; *C. sellovi*, *C. thoreyi*, *C. vicina* Thery (=*C. nitida* v. Rothk.) and *C. sanguinipennis* Mnh. (=*C. floricola* Obbg.), critically compared; *C. plebeja* v. Rothk. is considered a ssp. of *C. subdilatata* Saund.; *C. ulei* is distinct from *C. principalis*; *C. p.* ab. **insignata** (p. 156), Rio Grande do Sul; *C. rogersi** Saund. (=*C. flavipennis** Kerr.); *C.* **erudita** (*C. nigroviolacea* Obenb., not Deyrolle) (p. 158); *C.* **moluccana** (*C. viridipunctata* Blanch., not Cast. et Gong.) (p. 158); *Hyperantha interrogationis*, comparison of vars. *cruentata* and *bella*; *Coraebosoma* **carteri** (p. 159), Luzon [P. I.], type in Zool. Mus., Berlin; *Polyonychus* **fisheri** (p. 161), Candanduani Is., P. I., type in Zool. Mus., Berlin; *Tetragonoschema* **cupreocingulatum** (p. 163), Bolivia, type in Zool. Staatsmus. München.

14736. JORDAN, KARL. Anthribidae versus Platystomidae. *Novitates Zool.* 36(3): 281-287. 1931.—The author considers W. D. Pierce unjustified in his decision that the type of *Anthribus* Geoffrey is *Dermestes pulicarius* L., and maintains that if Geoffrey's work is accepted, the type should be one of those figured, and accepts Latreille's 1810 designation of *A. latirostris* Fab. If Geoffrey is not accepted, he believes that the genus should hold from Forster 1771, for which he designates *A. fasciatus* as type.

14737. JORDAN, KARL. Anthribidae collected by F. C. Drescher on the island of Java. *Novitates Zool.* 36(3): 288-302. 4 fig. 1931.—A record of 51 spp. including: *Acorynus lineolatus* ssp. **slamatus** (p. 288); *Litocerus figuratus* ssp. **notalis** (p. 289); *L.* **xenopus** (p. 289); *Hucus* **concinnus** (p. 290); *Zygaenodes* **rectimargo** (p. 291); *Z.* **leptipus** (p. 292); *Uncifer* **hapalus** (p. 292); *Nessiara* **cognata** (p. 293); *Apatenia viduata* ssp. **promota** (p. 294); *Hypseus* **cyphus** (p. 295); *H.* **scaphidius** ♀ (p. 295); *Phaulimia* **lineosa** ♀ (p. 296); *Sintor* **floridus** (p. 296); *Cleorisintor* **drescheri** ♂ (p. 297); *Xylinades westermanni* Gyll. (=*X. vicinus* Jordan); *X. nodicornis* Weber (=*X. westermanni* Gyll. var. β); *Phloeobius* **facilis** (p. 298); **ADOXASTIA** (p. 299), near *Protaedus*, type *A.* **drescheri** ♂* (p. 299); *A.* **trux** ♀* (p. 300); *Misthosima* **badia** (p. 301); **EPIDYSNOS** (p. 301), near *Dysnos*, type *E.* **procer** (p. 301); *Dysnos sericeus* Jord., referred to *Epidysnos*.

14738. JORDAN, KARL. Two new oriental Anthribidae. *Novitates Zool.* 36(3): 303-304. 1931.—*Zygaenodes* **kalshoveni** (p. 303), Brit. India; *Araecerus* **conabilis** (p. 303), Java, from fruits of *Podocarpus*.

14739. JORDAN, KARL. Some Anthribidae from tropical Africa. *Novitates Zool.* 36(3): 305-310. 1 fig. 1931.—*Mecocerus* **gratus** (p. 305) and *Syntophoderes* **simplicipes** (p. 305), Belgian Congo, types in Mus. Belgian Congo; *S.* **phrator** (p. 305), Belgian Congo (type), Gabon, and Cameroon; *Anthribus* **ornaticollis** (p. 306), French Congo and Cameroon, type in Carnegie Mus.; *Zygaenodes* **auritus*** (p. 306), Belgian Congo, type in Mus. Belg. Congo; *Epicerastes* **adustus** ♀ (p. 307), Cameroon (type, in Carnegie Mus.) and Belgian Congo; *E.* **muscosus** (p. 307), Cameroon, type in Carnegie Mus.; *E.* **exstans** (p. 308), Belgian Congo; *E.* **latimanus** ♂ (p. 308), Nyasaland; *E.* **musculus** (p. 308), Cameroon; *Epicerastes*, key to 14 spp.

14740. JUREČEK, ŠT. Eine neue Aberration von Lebia bifenestrata Mor. (Col. Carabidae). *Ent. Nachrichtenbl.* 5(1): 7. 1931.—*Lebia b.* ab. **obscura**, Siberia.

14741. JUREČEK, ŠT. Eine neue Aberration von Judolia longipes Gebl. (Col., Cerambycidae). *Ent. Nachrichtenbl.* 5(1): 8. 1931.—*Judolia l.* ab. **erythruroides** ♀, e. Siberia, type in O. Reiss coll.

14742. KANABÉ, DESIDER. Über Irrtümer in den Beschreibungen von Judolia (Pachytodes) cerambyciformis Schrank. ab. efasciata Csiki. und ab. transsylvanica Csiki. *Ent. Nachrichtenbl.* 4(3): 65. 1930.—*J. cerambyciformis* ab. **immaculata**, type in author's coll., with notes on the above mentioned aberrations.

14743. KLEINE, R. Die Cautires-Arten des Congo-Museums nebst Bestimmungsschlüssel der afrikanischen Arten. *Rev. Zool. et Bot. Africaines* 19(1): 4-19. 1 pl. 1930.—A study of a collection of Lycidae from Congo Mus., chiefly of spp. of *Cautires*, including: *C.* **congonus** ♂* (p. 4), **costulatus** ♀* (p. 5), **opacicollis** ♀* (p. 5), **lamellatus** ♂* (p. 5), **ochraceipennis** ♂* (p. 6), **triangularis*** (p. 6), **maculatithorax** ♂* (p. 7), **flavipennis** ♂* (p. 7), **seydeli*** (p. 7), **africanus** ♀* (p. 8), **schoutedeni** ♂* (p. 8), **constans** ♀* (p. 8), **reticulatus** ♂* (p. 9), **gracilis*** (p. 9), **certus*** (p. 9), **flavofemoralis** ♀* (p. 10), and **aethiops** ♂* (p. 10), apparently all from Belgian Congo. Key is given to the African spp.

14744. KNOWLTON, GEO. F. Notes on Utah Coleoptera. *Florida Ent.* 14(2): 36-37; (3): 53-56; (4)

75-77. 1930; 15(1): 10. 1931.—A list of spp., with collecting records, based on examination of the coll. at Utah Agric. Exp. Sta.

14745. **LIEBKE, MAX.** Laufkäfer-Studien VII. Zwei neue Carabiden-Arten aus Südost-Asien. *Ent. Anzeiger* 11(13): 261-263. 2 fig. 1931.—*Dinopelma* **minor*** (p. 261), Borneo (type), west Sarawak; *Mastax* **latefasciatum*** (p. 262), Annam. Types in author's coll. *Lebia* **atricapilla** (*L. putzeysi* Lbk., not Bedel) (p. 263).

14746. **MACHULKA, VÁCLAV.** Beitrag zur Synonymie der palaearktischen Pselaphiden. *Časopis Čsl. Spol. Ent.* 26(5/6): 119-121. 1930.—*Batrisodes buqueti* Aubé (=*B. hubenthali* Reitter); *Pselaphus xanthopterus* Reich. and *Tychus dichrous* Schmidt are discarded as unrecognizable; Aubé, not Schmidt, is considered the author of *Reichenbachia opuntiae*; *Tychus niger* ab. **bohemicus** (p. 120), Czechoslovakia; *Bythinus monstrosetibialis* Stolz (=*B. trojani* Fleischer), emended description; *Bythinus* (=*Megalobythus* Jeannel, *Macrobythus* Raffray).

14747. **MAMITZA, RICHARD.** Ein neuer Heterocerus aus Abessinien. *Ent. Nachrichtenbl.* 4(4): 85-86. 4 fig. 1930.—*H.* (s. str.) **abyssinicus*** (p. 85), type in Brit. Mus.

14748. **MARSHALL, GUY A. K.** New species of African Brachycerus (Col., Curc.). *Ann. and Mag. Nat. Hist.* 7(40): 409-424. 1 pl. 1931.—*B.* **terrenus*** (p. 409), Tanganyika and Nyasaland; *B.* **canus** (p. 410), S. W. Africa; *B.* **vansomereni** ♂ (p. 412), Kenya; *B.* **suahilicus*** (p. 413), Rhodesia, Portuguese E. Africa, Nyasaland; *B. s.* ssp. **reductus** (p. 415), Rhodesia, Tanganyika, Kenya; *B.* **deludens** (p. 415), Nyasaland; *B.* **erosicollis** ♂ (p. 416), Portuguese E. Africa, Tanganyika, Rhodesia; *B.* **grandicallosus*** (p. 417), Portuguese E. Africa, Nyasaland, Tanganyika, Zanzibar; *B.* **lupatus** (p. 419), Tanganyika, type in Hamburg Mus.; *B.* **microderes*** (p. 420), French Congo, Cameroons; *B.* **rasicollis*** (p. 422), Rhodesia, Nyasaland; *B.* **basidentatus*** (p. 423), Kenya, Tankanyika.

14749. **MIWA, YUSHIRO.** Elateridae of Formosa (V.). *Trans. Nat. Hist. Soc. Formosa* 22(113): 72-99. 1931.—*Corymbites gratus* v. **fuscipes** (p. 72); *Agriotes sonanis* v. **brunneipennis** (p. 78) and v. **nigrinus** (p. 78); *Denticollis* **puerilis** (p. 83); *D.* **mounaldaui** (p. 83). Keys are given to the genera and spp. as well as a list of geographical distribution.

14750. **OBENBERGER, JAN.** Einige Bemerkungen zur Verbreitung und Synonymie von afrikanischen Meliboeus-Arten (Col., Buprestidae). *Folia Zool. et Hydrobiol.* [*Riga*] 2(2): 172-175. 1931.—Notes on 12 known spp.

14751. **OGLOBLIN, A. A.** Beitrag zur Kenntnis der neotropischen Halticinen. I. *Rev. Soc. Ent. Argentina* 3(1): 47-52. 1 pl. 1930.—*Longitarsus* **brunnipes** (p. 47), Argentina, and *L.* **pallipes*** ♂ (p. 47), southern Brazil, types in author's coll.; *L.* **fryellus*** (p. 48), Brazil and Argentina; *L.* **mendax*** ♂ (p. 49), type in author's coll. and *L.* **vicarius*** (p. 49), Argentina; *L.* **frontalis*** (p. 50), Rio Grande do Sul, Sao Paulo, and Argentina; *Chaetocnema* (*Tlanoma*) **fuscipes** (p. 51), Argentina; *C.* (*T.*) **gibbosa*** (p. 52), Brazil, type in author's coll.

14752. **OKE, CHARLES.** On some Australian Curculionoidea. *Proc. Roy. Soc. Victoria* 43(2): 177-201. 6 fig. 1931.—*Ecrizothis* **similis** (p. 177); *E.* **blackburni*** (p. 178); *E. inaequalis*; *E. bovei*; *E.* **terminalis*** (p. 179); *Polyphrades* **viridis** (p. 179); *Leptops* **nothus*** (p. 180); *L. phymatodis*; *Mandalotus acanthocnemis*; *M. bivitticollis* and *M. pentagonoderes*, emended descriptions; *M.* **leai*** (p. 184); *M.* **impressicollis*** (p. 185); *M.* **bryophilus*** (p. 186); *M.* **graminicola** (p. 186); *M.* **explanicollis*** (p. 188); *M.* **octagonalis*** (p. 188); *M.* **minusculus** (p. 189); *M.* **egenus** (p. 190); **MANDALOTINA** (p. 190), near *Mandalotus*, type *M.* **atranotata*** (p. 190); *M.* **varia** (p. 191); *M.* **bicolor** (p. 191); *Phrynixus*, emended description; *P.* **victoriae*** (p. 192); *P.* **sylvicola** (p. 193); *P.* **major*** (p. 194); **DAYLESFORDIA** (p. 195), tentatively placed in Rhyparosominae, type *D.* **uvida*** (p. 195); **DIXONCIS** (p. 196), doubtfully referred to Aterpinae, type *D.* **pictus*** (p. 196); *Rhinoncus* **australis** (p. 198); *Dicthosa* **setosa** (p. 198), on *Acacia pycnantha*; *D.* **venusta** (p. 199); *Blepiarda* **panacis*** (p. 199); **NYELLA** (p. 200), of uncertain position, perhaps near Tryxetini, type *N.* **tuberculata*** (p. 200). All new spp. from Victoria, types in author's coll.

14753. **PIC, M.** Nouveaux Malacodermes et Hétéromères de la République Argentine. *Rev. Soc. Ent. Argentina* 1(3): 13-16. 1927.—*Astylus* **griseopubens** (p. 13); *A.* **bruchi** (p. 13), and var. **interna** (p. 14); *Attalus* **bruchi** (p. 14); *Mauronisces* **maculatus** (p. 14); *Chauliognathus* **caroli** (p. 15); *Macrosiagon nigromaculatum* v. **bruchi** (p. 15); *M.* **semilimbatum** (p. 16).

14754. **PIC, M.** Nouveaux coléoptères malacodermes de l'Amérique Méridionale. *Rev. Soc. Ent. Argentina* 2(1): 35-36. 1928.—*Leucothrix* **argentina** (p. 35); *Calopteron* **wagneri** (p. 35); *C. maculatum* vars. **mediobliteratum** and **ignaciosum** (p. 35); *Chauliognathus* **bilineaticollis** (p. 35), *C. b.* var. **semiconnexus** (p. 35), Argentina and Paraguay; *C.* **nigrolateralis** (p. 36) and *C.* **erratus** (p. 36), South America; *Discodon* **criollanum** (p. 36); *D. c.* vars. **mediojunctum** and **suturiferum** (p. 36), *D.* **laticolle** (p. 36); *Silis* **vagelimbatus** ♂ (p. 36). All from Argentina unless otherwise stated, and types in author's coll.

14755. **PORTEVIN, G.** Histoire naturelle des Coléoptères de France. Vol. 1. Adephaga,—Polyphaga: Staphylinoidea. In: *Encyclopédie Entomologique Ser. A*, No. 12. x+649p. 5 col. pl., 571 fig. Paul Lechevalier: Paris, 1929.—An extensive study, including notes on the general characteristics of Coleoptera, with figures to clarify the terminology. The systematic part is in the form of keys, with many figures. There are keys to suborders, families, subfamilies, tribes, genera, subgenera, and spp. For each genus there are brief notes on habits and habitat, with notes on larval characters if known (including citations of larval descriptions), and distribution in France. Species from Corsica are included. There is an alphabetical index to all names. The following new subgenera are proposed: **DEROGRAPHUS** (p. 210), n. subg. of *Graphoderes*, erected for *G. austriacus* Stm.; **QUEDIOPSIS** (p. 337), n. subg. of *Quedius*, erected apparently for *Q. riparius* Kelln. and *Q. kraatzi* Ch. Bris.; **LATHROBIDIUM** (p. 382), n. subg. of *Lathrobium*, erected for *L. lusitanicum* Grav.; **CHAETODERUS** (p. 602), n. subg. of *Plegaderus*, erected for *P. pusillus* Rossi; **CHETABRAEUS** (p. 604), n. subg. of *Abraeus*, erected for *A. globulus* Creutz. The genus *Xanthosphaera* Fairm. is considered hypothetical, being based upon a single, apparently composite specimen, consisting in part of a *Triarthron*, in part of a *Cyrtusa*.

14756. **REINECK, GEORG.** 4. Beitrag zur Lebens- und Entwicklungsweise von Coleopteren. *Zeitschr. Wiss. Insektenbiol.* 24(7/8): 220-226. 10 fig. 1929.—The life history of *Chrysochloa rugulosa** Suffr. is described. The host plants are *Centaurea scabiosa* L. and *C. jacea* L. The life from egg to adult takes about 4 months. Pupation takes place in the soil. The sp. is found throughout French Switzerland to the country south of Staffelberges in Bavaria. The occurrence of *Chrysochloa tristis* v. *smaragdina* Ws. in French Switzerland is noted as an error. The life history is given of *Chrysomela aurichalcea* v. *asclepiadis* Villa, taken from stony slopes near Muggendorf and Doos in Franconia on *Vincetoxicum officinale** Moench. The ♀♀ hibernate and appear in the spring for egg-laying. Breeding experiments are therefore difficult.—*G. Reineck* (*transl. by J. A. Reeves*).

14757. **ROUBAL, J.** Vier neue Coleopteren aus U. S. S. R. *Ent. Blätter* 25(1): 46-48. 1929.—*Geodromicus* **lebedevianus** (p. 46), Asiatic Russia; *Monotoma brevicollis* ssp. **lebedevi** (p. 47), central Asia; *Mycetophagus multipunctatus* ssp. **sulcatulus** (p. 47), n. Caucasus; *Mordellistena* **lebedevi** (p. 48), central Asia.—*M. H. Hatch.*

14758. **RÜSCHKAMP, F.** Zur rheinischen Käferfauna III. *Ent. Blätter* 24(4): 145-154. 1928.—Annotated list of 143 spp. from Rhenish Prussia, with special notes on *Hygrotus versicolor* Schall., *Hydroporus dorsalis* F.,

Gyrophaena rugipennis Muls. et Rey, *Hydraena gracilis* Germ., *Endomychus coccineus* L., *Cytilus auricomus* Dtfs., *Melanotus rufipes* Hrbst., *Anaspis regimbarti* Schils.—*M. H. Hatch.*

14759. **RÜSCHKAMP, F.** Zur rheinischen Käferfauna IV. *Ent. Blätter* 25(1): 35-43. 1929.—Annotated list of 97 spp. from Rhenish Prussia, with special notes on *Harpalus quadripunctatus* Dej., *Paracymus scutellaris* Rosenh., *Brachypterus glaber* Steph., *Pentaphyllus chrysomeloides* Rossi and *P. testaceus* Helw.—*M. H. Hatch.*

14760. **SCHAEFFER, CHAS.** On some species of Phaedon. *Bull. Brooklyn Ent. Soc.* 24(5): 286-287. 1929. —*P. carri* Hatch is a valid sp., and not a synonym of *P. cochleariae* Fab.; *P.* americanus (p. 287), Michigan (type), Idaho and Washington.

14761. **SCHEDL, K.** Notes on the Pityophthorinae (Coleoptera Ipidae). II. Three new species. *Canadian Ent.* 63(7): 163-168. 1 pl. 1931.—*Pityophthorus* smithi* (p. 163), Brit. Columbia, from twigs of *Pinus contorta; P.* pygmaeus ♀* (p. 165), Quebec; *P.* pilifer* (p. 166), Ontario, from *Picea canadensis*. Types in Canadian Nat. Coll., Ottawa.

14762. **SICARD, A.** Descriptions d'espèces nouvelles appartenant à la famille des Coccinellides (Col.). *Ann. and Mag. Nat. Hist.* 8(45): 228-234. 1931.—*Vibidia* tricincta (p. 228), Uganda; *Rodolia* obscuricollis (p. 229), Cape Province, feeding on *Icerya euphorbiae* on *Euphorbia; Scymnus* (*Pullus*) luniferus (p. 229), Tanganyika; *S.* (*Sidis*) ancoralis (p. 230), Kenya; *S.* c-luteum (p. 231), Uganda; *S.* ardosiacus (p. 232), Gold Coast, predator on *Aspidiotus destructor; S.* erinaceus (p. 232), Fiji; ORCULUS (p. 233), near *Orcus*, based on *O.* castaneus (p. 234), Sierra Leone. Types in Brit. Mus.

14763. **THÉRY, A.** Notes d'entomologie Marocaine et Nord-Africaine. (Septième note.) *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 90-91. 1929.—*Labidostomis* embergeri ♂ (p. 90), Morocco.

14764. **THÉRY, ANDRÉ.** Buprestides nouveaux d'Afrique. (Deuxième note.) *Bull. Soc. Sci. Nat. Maroc* 9(7/8): 139-171. 4 fig. 1929.—*Amblysterna* somereni* (p. 139); *Steraspis lemoulti* ssp. carpenteri (p. 140), Uganda; *Iridotaenia* camerunica (p. 141), Nigeria; *Polybothris* blairi (p. 143), Madagascar, type in Brit. Mus.; *P.* natalensis* (p. 144), Natal, type in Natal Mus.; *Sphenoptera* (*Hoplistura*) braunsi* (p. 146), Transvaal; *S. b.* ssp. carpenteri* (p. 148), *S.* (*H.*) madiensis* (p. 148) and *S.* stupida (p. 150), Uganda, types in Imperial Inst. of Entomology; *Anthaxia* (*Cratomerus*) hunti (p. 152), Kenya, type in Brit. Mus.; *A.* (*C.*) maracaensis (p. 153), Abyssinia; *A.* monbasica (p. 154), Kenya; *A.* vulpes (p. 156), Cameroon; *Damarsila albomarginata* ssp. ugandae (p. 157) and *D.* carpenteri (p. 158), Uganda, types in Imp. Inst. Ent.; *Megactenodes* raffrayi (p. 160), Abyssinia (type) and Brit. East Africa; *Strigulia* bottcheri (p. 161), Rhodesia; *S.* auberti (p. 162), Gabon; *Discoderes salzmanni* v. carpenteri (p. 163), Uganda, type in Imp. Inst. Ent.; *Sambus* sulcicollis (p. 163), Natal, type in Natal Mus.; *Cryptodactylus* abyssinicus (p. 165), Eritrea; EUMORPHOCERUS (p. 166), near *Evimantius*, based on *E.* laticornis (p. 167), Madagascar; DISCODEROPSIS (p. 168), near *Paradora*, based on *D.* incurvatus (p. 169), Madagascar; *Agrilus* australis (p. 170), Natal, type in Imp. Inst. Ent. Unless otherwise stated, the types are in the author's coll.

14765. **UHMANN, E.** Hispinen aus dem holländischen Kolonialgebiet. *Zool. Mededeel.* [*Leiden*] 13(3/4): 178-179. 1 fig. 1930.—Chrysomelidae: *Botryonopa* kleinei (p. 178), Borneo, type in Deutsch. Ent. Inst., Berlin-Dahlem; *Metaxycera purpurata, Sceloenopla maculata, S. quinquemaculata,* and *Amplipalpa collaris* are new to Surinam; new descriptive data on *Hispa fabricii,* and *Dactylispa cincta**.

14766. **URBAN, C.** Beiträge zur Naturgeschichte einiger Rüsselkäfer. I. *Ent. (p. 183); *Paralimna* **punctipennis** (*Notiphila p.* Wiede.,=*P. appendiculata* Loew) (p. 184); *P.* **sana** (p. 185), Paraguay; *P.* **nubifer** (p. 187), Congo; *P. puncticollis* (=*Poecilothorax angustus* Becker); *P.* **sinensis** (*Notiphila s.* Schiner) (p. 189); *P.* **concors** (p. 189), Philippine Isls., type in U. S. Nat. Mus.; *P. hirticornis* Meij. (=*P. nitens* Bezzi); *P. molosus* Schiner (=*P. puncticornis* v. *captiosa* Cresson); *P. confluens* Loew (=*P. ornatipennis* Adams); *Phaiosterna* **aequalis** (p. 193), French Indo-China; *Typopsilopa* **chinensis** (*Notiphila c.* Wiede.); *T.* **tonga** ♀ (p. 194), Egyptian Sudan. Types in Acad. Nat. Sci. Philadelphia, unless otherwise stated.

14778. CRESSON, EZRA T. Jr. Studies in the dipterous family Ephydridae. Paper III. *Trans. Amer. Ent. Soc.* 56(2): 93-131. 1930.—Representing results of a study of the Ephydridae in the coll. belonging to Naturhist. Mus., Wien, and other material. *Hydrina flavipes* (Fallen) (=*Ephydra minuta* Meigen); *H. posticata* (Meigen) (=*Philygria nigricauda* Stenh.); *H.* **morans** (p. 98) and *H.* **tirolis** (p. 99), Austria; **NAPAEINAE** n. subfam. (p. 100), to include *Axysta*, *Hyadina*, *Pelina*, *Brachydeutera*, *Napaea*, *Parydra*, *Halmapota*, and possibly *Canace*, and allied genera, the group apparently intermediate between the Notiphilinae and Ephydrinae; *Nostima* **picta** (*Notiphila p.* Fallen) (p. 101); *Hyadina* **pullipes** (p. 103), New S. Wales; *Napaea* **mitis** (p. 110), Upper Austria; *N.* **consors** (p. 111), Dalmatia; **SETACERA** (p. 116), type *S.* **pacifica** (*Ephydra p.* Cresson) (p. 116); *S.* **micans** (*Ephydra m.* Haliday) (p. 116); *S.* **pedalis** (p. 117), Austria, type in Vienna coll.; *S.* **breviventris** (*Ephydra b.* Loew) (p. 117); *Lamprogaster* Hendel, critical note; **EUSTIGOPTERA** (p. 126), type *E.* **quadrata** (*Notiphila q.* Fallen) (p. 127); *E.* **pauciguttata** (*Scatella p.* Strobl) (p. 127); *E.* **stenhammari** (*Ephydra s.* Zetterstedt) (p. 128); *Scatophila* **quadriguttata** (*Ephydra q.* Meigen) (p. 130). Types in Acad. Nat. Sci., Philadelphia, unless otherwise stated.

14779. CURRAN, C. H. New species of Diptera belonging to the genus Baccha Fabricius (Syrphidae). *Amer. Mus. Novitates* No. 403. p. 1-16. 1930.—*Baccha* Fabr. (=*Oeyptamus* Macq.). A key to 59 spp. of *Baccha*, new and recent synonymy of spp. and the following descriptions are given: *B.* **telescopica** ♀ (p. 4), *B.* **vierecki** (p. 6), *B.* **shropshirei** ♀ (p. 7), *B.* **zeteki** (p. 8), *B.* **panamensis** (p. 9), *B.* **nitidula** ♂ (p. 9), all from Canal Zone; *B.* **atypica** (p. 10), *B.* **prenes** ♂ (p. 11) and *B.* **murina** ♂ (p. 12), Brazil; *B.* **mentor** and *B.* **macer** ♂ (p. 13), Paraguay; *B.* **deceptor** (p. 14), West Indies; *B.* **chapadensis** ♀ (p. 14), Brazil; *Baccha* **mexicana** (*B. lugubris* Williston, preocc.) (p. 6); *B. gastrostactus* Wied., notes distinguishing the ♂ and ♀; *B. lineata* Macq. (=*B. tropicalis* Townsend); *B. obscuricornis* Loew ♀ (=*B. cognata* Loew ♂).

14780. CURRAN, C. H. New Syrphidae from Central America and the West Indies. *Amer. Mus. Novitates* No. 416. p. 1-11. 1930.—*Megametopon* **violacea** (p. 1) and *Copestylum* **bequaerti** ♂ (p. 2), Mexico; *Volucella*, key to 3 spp., including: *V.* **watsoni** (p. 3), Haiti; *V.* **ingenia** ♀ (p. 4), Bahamas; *V.* **feminina** ♀ (p. 4) and *V.* **ernestina** ♂ (p. 5), Mexico; *Microdon* **apiculus** (p. 5), "Barro Colorado Is."; *M.* **panamensis** (p. 6), "France Field"; *M.* **solitaria** ♀ (p. 8) and *Callostigma* **panamensis** ♀ (p. 8), Barro Colorado Is.; *Xanthandrus* **mexicanus** ♀ (p. 9), Mexico; *Ceriogaster* **panamensis** ♂ (p. 10) and *Meromacrus* **panamensis** ♂ (p. 11), Barro Colorado Is. The author believes that *Melanostoma ?eucephalus* Bigot, from Colombia, is the same as *bucephalus*.

14781. CURRAN, C. H. Review of the African species of Sphyracephala, Say. *Ann. and Mag. Nat. Hist.* 2(9): 274-275. 1928.—*Sphyracephala* **munroi** ♀ (p. 274), Transvaal, type in Munroe coll.; key is given to differentiate *munroi*, *africana*, and *beccarii*.

14782. CUTHBERTSON, ALEXANDER. Studies on Clyde crane-flies. VIII. The seasonal prevalence of crane-flies (Tipuloidea. Dipt.) in the West of Scotland. *Entomologist* [*London*] 62(799): 270-273. 1929.—A list of 8 spp. found in winter, 35 in spring, 46 in summer, and 24 in autumn; 26 spp. occur from May to September. The largest percentage of spp. occurs in June.

14783. DYAR, HARRISON G. The mosquitoes of the Americas. *Carnegie Inst. Washington. Publ.* 387. 616p. 123 pl. 1928.—A monograph covering the classification of mosquitoes of the North- and South-American continents. The classification adopted is not materially altered from the one, used in a previous edition, published by Howard, Dyar, and Knab, dealing with the mosquitoes of North and Central America and the West Indies, of which the present monograph is a supplement. The revised edition comprises the family Culicidae, subfamily Culicinae with the tribes Sabethini, Culicini, Megarhinini, Uranotaeniini and Anophelini, including the genera: *Sabethes*, *Sabethoides*, *Limatus*, *Wyeomyia*, *Miamyia*, *Menolepis*, *Dendromyia*, *Goeldia*, *Joblotia*, *Psorophora*, *Haemagogus*, *Aëdes*, *Culicella*, *Mansonia*, *Deinocerites*, *Lutzia*, *Culex*, *Aëdeomyia*, *Orthopodmyia*, *Megarhinus*, *Uranotaenia* and *Anopheles*. The

figures refer in the main to the ♂ hypopygium of the various spp. listed, to a diagram of the lateral view of thorax of mosquito and to a diagram of mosquito larva (*Culex*).—*C. Zeimet.*

14784. **GEMIGNANI, EMILIO V.** Las especies argentinas del género Mallophora (Dipt.) y descripsión de cuatro nuevas especies. [Argentine spp. of Mallophora and descriptions of four new spp.] *Rev. Soc. Ent. Argentina* 3(2): 133-144. 2 fig. 1930.—A review of the characteristics of the genus and of 15 spp. represented in the Mus. Nac. Hist. Nat. Buenos Aires. Bibliographical references, descriptions, and locality records are given for the old spp. *Mallophora* **doello-juradoi** (p. 136); *M.* **copelloi** ♂ (p. 138); *M.* **lynchi** ♂ (p. 141); *M.* **zottai** ♀ (p. 141).

14785. **[GONCHAROV, G. D.]** ГОНЧАРОВ, Г. Д. Питание личинок **Anopheles maculipennis** в искусственных условиях. [Larval feeding of A. maculipennis in artificial conditions.] [French summary.] Русский Журнал Тропической Медицины [*Russian Jour. Trop. Med.*] 6(8): 482-488. 2 fig. 1928.—Larvae in all stages were omnivorous; their stomach contents showed a mass of fine granules (sand), vegetable matter (especially Volvocales and Protococcales), and animal matter (predominantly Rotatoria). Plankton of the reservoirs was directly related to these contents,—larvae absorbed the predominant forms. In II, III, and IV stages the author noticed progressive increase of animal matter, corresponding to the development of buccal and digestive apparatus. Lack of Ca in the water was compensated by rich food resources.—*B. Van Rosen.*

14786. **KRÖBER, O.** Die Tabanidenuntergattung Phaeotabanus Lutz. *Zool. Anz.* 86(11/12): 273-300. 21 fig. 1930. —The author includes in this subg. 22 spotted-winged spp. of *Tabanus*, his conception of the group differing somewhat from that of Lutz. The group is widely distributed in South America and extends north to Costa Rica. There is a key to the ♀♀ of nearly all spp. and to the ♂♂ of a few spp. The systematic accounts of the spp. include citation of the type, description, geographical distribution, and figures of front, palp, antennae, and wing. The subgeneric name is used throughout in binomial combination. *Phaeotabanus* **ecuadoriensis** ♀* (p. 279), Ecuador, type in Halle; *P.* **unimaculatus** ♀* (p. 280), Dutch Guiana, type in Halle; a ♀ from Brazil, in the Winthem collection at Vienna, is designated as the type of *P. aphanopterus* Wied.; *P. a.* var. **obscurehirtus** ♀* (p. 284), British Guiana, type in London; *P.* **minor** ♀* (p. 284), Brazil, type in Vienna; *P.* **nigriflavus** ♂* (p. 285), French Guiana, type in author's coll.; *P.* **semiflavus** ♀ (p. 288), Venezuela, type in author's coll.; *P. apicalis* Wied. (= *Tabanus tinctipennis* Brèth.); *P.* **austeni** ♀* (p. 294), Peru, type in London; *P.* **multiguttatus** ♀* (p. 295), Colombia and Ecuador type in author's coll.; *P.* **tenuifasciatus** ♀* (p. 296), Peru, type in Dresden; *P.* **ocelligerus** ♀* (p. 296), Costa Rica, type in Vienna; *P.* **pallidetinctus** ♀* (p. 297), Panama, type in London; *P.* **reticulatus** ♀* (p. 298), Peru, type in author's coll.; *P.* **formosus** ♀* (p. 299), Costa Rica, Colombia, and Ecuador, type in author's coll.

14787. **MARELLI, CARLOS A.** La Agromyza productora de agallas nodícolas en la lagunilla y sus parásitos e hiperparásitos. [The Agromyza which produces knotted galls on "lagunilla" (Alternanthera philoxeroides) and its parasites and hyperparasites.] *Rev. Soc. Ent. Argentina* 1(2): 13-21. 1 fig. 1926.—Galls* from the roots of *Alternanthera philoxeroides*, produced by *Agromyza marellii* Brèthes, contain also various parasites of the latter, including *Hypolethria bonariensis* [Cynipidae], *Habrocytus platensis* [Chalcididae], and *Mymarilla agromizae*, which often kill the larval *Agromyza*. The size of the gall gives an indication of which sp. will emerge from it. Another parasite of *A. marellii* is a mite, *Dipterolelaps manganaroi* "n. g. n. sp." (nomen nudum).

14788. **MEIJERE, J. C. H. de.** Die Larven der Agromyzinen (Fortsetzung und Schluss). *Tijdschr. voor Ent.* 69(3/4): 227-317. 69 fig. 1926.—The first part of this work was published *Ibid.* 68: p. 195-293. 1925, and dealt with the genera *Agromyza, Domomyza, Melanagromyza, Ophiomyia, Dizygomyza,* and *Liriomyza,* to which a supplement is given in this part (p. 303-307), containing a critical discussion of S. W. Frost's work (1924) on North American leaf-miners, as well as additional notes on several spp. of the above genera. The present part gives critical notes and descriptions of larvae and adults of *Napomyza*, Pseudonapomyza*, Phytagromyza*, Cerodonta*,* and *Phytomyza,* including *P.* **avenae*** (p. 251) and *P.* **pratensis*** (p. 284). Indexes to generic and specific names and to host plants conclude the paper.

14789. **MEILLON, BOTHA de.** On the Ethiopian Simuliidae. *Bull. Ent. Res.* [*London*] 21(2): 185-200. 6 fig. 1930.—For easy field identification, keys to the ♀♀ are given, and use of the illustrations of ♂ genitalia and pupal filaments is urged, in addition. The following are new: *Simulium* **bovis*** ♀ (p. 188), Zululand; *S.* **blacklocki*** Edwards (p. 189), Sierra Leone, type in British Mus.; *S.* **woodi*** ♀ (p. 190), Nyasaland; *S.* **nyasalandicum*** ♀ (p. 190), Nyasaland, type in Brit. Mus.; *S. nigritarsis* Coq., ♂ described for first time and ♀ redescribed.

14790. **MUKERJI, S.** Morphology of the pharynx of female Culicoides and its taxonomic importance. *Nature* [*London*] 127(3201): 339-340. 1 fig. 1931.—Examination of the pharynx in *C. pulicaris, C. oxystoma,* and *C. peregrinus,* indicates considerable variation in the structure which may be of taxonomic value.

14791. **PARENT, O.** Diptera vrachycera. 1. Dolichopodidae. (Ent. Results of the Swedish Kamchatka Exp. 1920-1922.) [In French.] *Arkiv. Zool.* [*Stockholm*] 21 A(2 No. 14): 1-7. 4 fig. 1930.—Of the 12 spp. collected, 6 are common all over Europe, 2 were hitherto known from palearctic Asia, and 4 are new: *Hydrophorus* **femoratus** ♂* (p. 2); *H.* **nigrihalteratus** ♂* (p. 3); *H.* **dubius** ♀* (p. 5); and *H.* **orientalis** ♀ (p. 5).

14792. **PARENT, O.** Contribution à la faune diptérologique (Dolichopodidae) des Pyrénées (versant français). *Butl. Inst. Catalana Hist. Nat.* 9(3): 56-72. 4 pl. 1929.—A list, with localities, of about 80 spp. collected by H. W. Brolemann, including: *Ludovicius* **spectabilis** ♂* (p. 58); *Hercostomus* **gavarniae*** (p. 62); *Campsicnemus* **mammiculatus*** (p. 64); *Medetera* **brolemanni*** (p. 69). Keys are given to differentiate the new spp. from closely related ones.

14793. **PARROT, L.** Sur une collection de Phlébotomes du Congo Belge. *Rev. Zool. et Bot. Africaines* 19(2): 181-192. 15 fig. 1930.—A list of 9 spp., including: *Phlebotomus* **brodeni** ♀* (p. 185); *P.* **rodhaini** ♂* (p. 187), type in Belgian Congo Mus., Tervueren; *P. minutus* v. *antennatus* Newstead and *P. squamipleuris* Newst., new to Belgian Congo.

14794. **PARROT, L.** Sur Phlebotomus rodhaini. *Rev. Zool. et Bot. Africaines* 20(2): 103. 1930.—Emended description.

14795. **ROHDENDORF, B.** Records of Sarcophagidae with new species. *Bull. Ent. Res.* [*London*] 21(3): 315-318. 3 fig. 1930.—*Sarcophaga* **sinica*** ♂ (p. 315) and *S.* **sera*** ♂ (p. 316), Foochow, China, types presumably in Imperial Inst. of Ent.

14796. **ROY, D. N., and BRUCE MAYNE.** A note on the presence of supernumerary lobes in salivary glands of anopheline mosquitoes. *Parasitology* 23(1): 77-78. 1 pl. 1931.—Records the finding of supernumerary lobes in 202 cases in *Anopheles quadrimaculatus*, A. punctipennis, A. subpictus*,* and *A. barbirostris**.

14797. **SHANNON, RAYMOND C.** Apropos "Masarygus" Brèthes. [In English.] *Rev. Soc. Ent. Argentina* 2(1): 37-38. 1928.—The author gives his reasons for considering *Masarygus* only a subgenus.

14798. **TAYLOR, ERNEST.** On the pupation of Cylindrotoma distinctissima Meig., a tipulid infesting Caltha palustris L. *North Western Naturalist* 6(1): 17-18. 1931.

14799. **VAN DUZEE, M. C.** New Dolichopidae from Connecticut. *Amer. Mus. Novitates* 439. 1-5. 1930.—*Mesorhaga* **caerulea** ♂ (p. 1); *Campsicnemus* **crassitibia** ♂ (p. 1); *C.* **curvispina** (*C. calcaratus* V.D. preocc.)

(p. 2); *Chrysotus* atratus ♂ (p. 2); *Argyra* fasciventris (p. 2); *Dolichopus* lobipennis ♂ (p. 3); *Hercostomus* (*Gymnopternus*) currani (p. 4). Types in Amer. Mus. Nat. Hist.

14800. VAN DUZEE, M. C. New species of Dolichopodidae taken by Mr. and Mrs. F. W. Edwards in South America. *Ann. and Mag. Nat. Hist.* 7(39): 243-255. 11 fig. 1931.—*Paraclius* edwardsi ♂* (p. 243), Argentina; *P.* brevimanus (p. 244), Uruguay; *Thrypticus*, key to spp.; *T.* penicillatus* (p. 246), Argentina; *T.* nigriseta ♂* (p. 247), Argentina; *T.* edwardsi (p. 248), Argentina; *Sympycnus* comatus (p. 249), Uruguay; *S.* flaviciliatus ♂ (p. 251), *Leptorhethum* tenuipes ♂ (p. 252), and *Condylostylus* ornatipes ♂ (p. 253), Argentina. Types in Brit. Mus.

14801. WEBBER, R. T. A new parasitic fly of the genus Chaetophlepsis. *Proc. U. S. Nation. Mus.* 78(20): 1-4. 1931.—*C.* orbitalis (p. 2), Massachusetts, reared from *Cingilia catenaria* Drury, type in Gipsy Moth Lab.

HEMIPTERA

14804. BAKER, ALEX. D. A study of the male genitalia of Canadian species of Pentatomidae. *Canadian Jour. Res.* 4: 148-220. 2 pl. 155 fig. 1931.—The development of knowledge of the ♂ genitalia of the Pentatomidae is indicated and other papers reviewed in the light of the writer's findings. Specialization of the 8th and subsequent segments is associated with the reproductive functions. Although often much reduced in size the 8th abdominal segment is always present. It is partially or completely retracted within the anterior segments. It bears no appendages. The considerable development of the intersegmental membranes adjacent to the 8th segment permits great mobility for the posterior genital carrying structures. The 9th segment is specialized for the accommodation of the genitalia. This is accomplished by the invagination of the posterior margin to form a bowl-like depression or "genital-cup." The claspers are homologized as originating from the primitive latero-caudal borders of the 9th sternum. The aedeagus arises from between the 9th and 10th sterna and has its most intimate connection with the 9th sternum. Structures termed the genital-plates are present in many species, chiefly among forms considered more primitive. The 10th segment is much reduced in size, existing as a small tail-like structure usually lying well within the genital-cup. This "proctiger" normally conceals and protects the aedeagus. The 11th segment is not apparent but there is a possibility that it may exist in the slightly sclerotized folds found bordering the anus. The anus opens at the distal end of the proctiger. The aedeagus varies considerably in form but the basic plan is clearly indicated. The basal plate of the aedeagus is made up of 4 sclerotized regions and 2 pairs of connectives, a ventral pair of connectives running to the infolded margin of the 9th sternum and a dorsal pair running dorso-cephalad. The aedeagus is articulated with its basal plate and continues distad as a sclerotized cylindrical structure, the penial theca, which encloses a large seminal reservoir. At the distal end of the penial theca the more thinly sclerotized penis is located. The penis may be 2- or 3-lobed. The ejaculatory duct has been traced from its distal end to an opening in the median sclerotization of the basal plate of the aedeagus. It is joined by a duct from the seminal reservoir in the penial theca. The ejaculatory duct terminates distad between the 2 lateral penis lobes. When a median lobe is present the duct passes through this structure. In some species a conspicuous penisfilum is present. A distinct connection between the claspers and the 9th sternum is present in certain species, which is independent of the aedeagal connections. The genital structures of the ♂ and ♀ are in their correct relation to each other when the insects assume the position of posterior to posterior. Owing to the great mobility of the genital segment this is not a necessary, nor the usual, initial position adopted during copulation. The functions of the claspers are apparently twofold: to assist in separating the genital sclerites of the ♀, and to assist as clasping organs during copulation. The aedeagus is capable of some extension beyond the limits of the genital-cup in addition to that brought about by the extension of the penis lobes. The movements of the basal plate and its connectives are described. In some species, the proctiger is capable of being partially withdrawn within the genital segment. In other species, slight dorsal flexion is possible. The movements allow for the protrusion of the aedeagus. In those species where a penisfilum is present, it is normally coiled in a clockwise direction, when viewed dextrad. Anticlockwise coiling, to the same extent, occurs within the median penis lobe. As a result when the penisfilum is extended uncurling is unnecessary and this organ and the adjacent portions of the ejaculatory duct merely undergo a compensating straightening of their parts. Description of the ♂ genitalia of a number of Canadian species of Pentatomidae is given. Only those structures normally visible, and therefore of greatest practical value, are made use of. In general the present grouping of species in the various subfamilies of this family is in harmony with these findings. Of the species studied, *Zicrona caerulea* and *Meadorus lateralis* exhibit the widest departures from the general features of their subfamilies. Some suggestions on the general line of

development of the genital structures are given. Evidences of primitiveness are suggested by: the direction of the opening of the genital-cup; size and degree of retraction of the 8th segment within the abdomen; degree of specialization of the proctiger, as to function and structure; the presence of genital-plates; absence of bulb, median penis lobe, penisfilum, etc., on aedeagus; absence of superior and inferior ridge, etc. Bibliography of 76 titles.—*A. D. Baker.*

(6000 ft.), Arizona; *P.* **demensus** (*Orthotylus d.* Van D.) (p. 8). Types (excepting one) in author's coll.

14811. KNIGHT, HARRY H. New species of Psallus Fieb. (Hemiptera, Miridae). *Canadian Ent.* 62(6): 125-131. 1930.—*Psallus* **amorphae** (p. 125), Minnesota (type), Iowa, host plants *Amorpha canescens* and *A. fruticosa; P.* **astericola** (p. 125), Iowa, host plant *Aster sericeus; P.* **fuscopunctatus** (p. 126), Colorado (9000 ft.), host plant *Artemisia frigida; P.* **cercocarpicola** (p. 127), Colorado, on *Cercocarpus parvifolius; P.* **nicholi** (p. 127), Arizona; *P.* **carneatus** ♀ (p. 128), California; *P.* **vaccinicola** (p. 128), Arizona (type), California, host plant *Vaccinium* sp.; *P.* **rubrofemoratus** ♂ (p. 129) and *P.* **atritibialis** (p. 129), Arizona; *P.* **flaviclavus** (p. 130), Colorado, host plant *Pinus ponderosa scopulorum; P.* **nigrovirgatus** (p. 130), Colorado (type), and New Mexico, host plant *Pinus ponderosa.* Types in author's coll.

HOMOPTERA

14812. BALL, E. D. Some new genera and species of leafhoppers related to Eutettix Van Duzee (Rhynchota Homoptera). *Florida Ent.* 15(1): 1-6. 1931.—Key to 4 genera; *Eutettix* **goniana** (p. 1) and *E.* **glennana** (p. 2), Arizona; *Opsius stactogalus* Amyot (= *Eutettix osborni* Ball); *Eutettix clarivida, E. insana, E. pauperula, E. tenella,* and *E. stricta* are referred to *Opsius* (p. 2); **NORVELLINA** (p. 2), near *Opsius,* type *Eutettix mildredae* Ball. This new genus is said to embrace 20 or more spp., but only the type and *Eutettix seminuda* and *E. chenopodii,* transferred to *Norvellina,* are cited; *N.* **oregona** (p. 3), Oregon; *N.* **helenae** (p. 3), Florida; *N.* **apachana** (p. 4), Arizona; **MENOSOMA** (p. 4), near *Eutettix,* type *M.* **stonei** (p. 5), Florida; *M.* **cincta** (p. 5) new comb.; *M. c.* var. **binaria** (p. 5), Florida; *M.* **acuminata** (Bak.) (p. 5), new comb.; *Athysanus litigiosus* Ball, transferred to *Menosoma; M.* **tortolita** (p. 6), Arizona. Types in author's coll.

14813. BALL, E. D. A supplemental revision of the genus Athysanus in North America. (Homoptera: Cicadellidae.) *Trans. Amer. Ent. Soc.* 55(1): 1-8. 1929.—A key to the North American genera including two new ones together with a description of food habits, distribution and new synonymy. **REMADOSUS** (p. 3), near *Athysanus,* resembling *Phlepsius,* key to North American spp., type *R.* **magnus** (*Athysanus m.* Osb. & Ball) (p. 4); **EXITIANUS** (p. 5), resembling *Euscelis* and *Athysanus,* type *E.* **obscurinervis** (*Jassus o.* Stål, = *Cicadula exitiosa* Uhler, *Athysanus picatus* Gibson, *A. miniaturatus* Gibs.) (p. 5); *Drylix,* key to North American spp.; *D.* **uneolus** (p. 6), Utah, type in author's coll.; *Euscelis* **obsoletus** (*Jassus o.* Kirschb., = *Athysanus relativus* Gill. & Baker, *Euscelis deceptus* Sand. & DeL.) (p. 7); *Ophiola* Edw., notes; *Commellus estacadus* Ball (= *Euscelis ozarcensis* Gibs.)

14814. CHINA, W. E. A new species of Erythroneura (Homoptera, Jassoidea) injurious to French beans (Phaseolus vulgaris) in the Sudan. *Bull. Ent. Res.* [*London*] 22(1): 53-54. 1 fig. 1931.—*E.* **lubiae*** (p. 53), Sudan, type in Imp. Inst. Ent.

14815. COCKERELL, T. D. A., and ELMER D. BUEKER. Some geophilous mealy-bugs from Australia (Homoptera: Coccoidea). *Amer. Mus. Novitates* No. 441. 1-7. 6 fig. 1930.—Root-feeding mealy-bugs of the *Ripersia* and *Ripersiella* group, found on roots of grass and *Rumex,* show a fairly wide distribution although the ♀♀ can crawl only a short distance. They have doubtless been disseminated from time to time by migrating birds, especially shore birds nesting on the ground. Being general feeders, they stand a good chance of survival in a new habitat. Diagnostic characters for *Phenacoccus, Puto, Heterococcus, Pseudococcus, Trionymus, Ripersia,* and *Rhizoecus* are discussed, and spp. of these genera compared. *Pseudococcus* **hystricosus*** (p. 4) and *Trionymus* **angustus*** (p. 6), New South Wales, types in American Mus. Nat. Hist.—*J. L. Buys.*

14816. FUNKHOUSER, W. D. New genera and species of neotropical Membracidae. *Jour. New York Ent. Soc.* 38(4): 405-420. 2 pl. 1930.—**CENTRONODUS** (p. 405), type *C.* **denticulus** ♂* (p. 405), Costa Rica; *C.* **flavus** ♀* (p. 406), Brazil; **OREKTHEN** (p. 406), near *Eustollia,* type *O.* **osborni** ♀* (p. 407), Chile; **DONTONODUS** (p. 407), type *D.* **serraticornis** ♀* (p. 408), Costa Rica; *Eustollia* **variegata** ♀* (p. 408), Chile, type in coll. Herbert Osborn; *Mina* **spinosa** ♀* (p. 409), Ecuador; *Campylocentrus* **nigris** ♂* (p. 410), Costa Rica; *Flexocentrus* **brunneus** ♂* (p. 410), Brit. Guiana; *Leioscyta* **pulchella** ♂* (p. 411), Brazil; *Erechtia* **trinotata** ♀* (p. 412), Argentina; **OREKTHOPHORA** (p. 412), type *O.* **cornuta** ♀* (p. 412), San Domingo; **SPINODARNOIDES** (p. 413), near *Paradarnoides,* type *S.* **typus** ♀* (p. 413), Porto Rico; *Alchisme* **projecta** ♂* (p. 414), Peru; *Tragopa* **bitriangulata** ♀* (p. 414), Matto Grosso, Brazil; *Antonae* **bulbosa** ♂* (p. 414), Mexico; *Poppea* **zebrina** ♂* (p. 416), Canal Zone; *P.* **nitida** ♂* (p. 416), Peru; *Maturna* **maculata** ♂* (p. 417), Colombia. Unless otherwise stated, types in author's coll.

14817. GODING, FREDERIC W. New Membracidae. *Jour. New York Ent. Soc.* 38(2): 89-92. 1930.—**PARAXIPHOPOEUS** (p. 89), in Centrotini, type *P.* **arebiensis**

(p. 89), N. W. Paulista; **XIPHIDIA** (p. 92), in Xiphistesini, type *Gongroneura carinata* Funkhouser.

14818. KNOWLTON, G. F. Studies on the morphology of the beet leafhopper, Eutettix tenellus (Baker). *Utah Agric. Exp. Sta. Bull.* 212. 24pp. 36 fig. 1929.—A study of its general external and internal morphology. Particular attention is paid to the digestive system and its accessory glands, as they appear to be the organs most closely associated with the transmission of the curly top disease of the sugar beet.—*G. F. Knowlton.*

14819. LAMBERS, D. HILLE RIS. Two new gall-forming species of Astegopteryx Karsch from Styrax. *Misc. Zool. Sumatrana* No. 55. 1-5. 4 fig. 1931.—Aphididae: *Astegopteryx* **vandermeermohri** (p. 1), alate* and apterous* viviparous ♀s, first instar larva; *A.* **sumatrana** (p. 4), alate* and apterous* viviparous ♀s, and first instar larva. Both species from Sumatra, forming galls on *Styrax subdenticulatus,* types in the author's coll.

14820. MYERS, J. G. New or little-known Australasian cicadas of the genus Melampsalta, with notes on songs by IRIS MYERS. *Psyche* 33(3): 61-77. 1 pl. 1926.—*Melampsalta* **sericea*** (*Cicada s.* Walk.,=*C. nervosa* Walk., *M. indistincta* Myers) (p. 62); *M.* **cassiope*** Huds. (song given) is not a synonym of *M. quadricincta** (Walk.); *M.* **melanesiana*** ♂ (p. 64), New Caledonia, type in Brit. Mus.; *M.* **oromelaena*** (p. 65), New Zealand, type in author's coll.; *M. mangu**, a lectotype is chosen, the species is redescribed, and its song recorded; *M. campbelli**, first descr. of ♂, record of song; *M.* **hamiltoni*** (p. 71), New Zealand, type in author's coll., record of song; *M. muta* Walk. is divided into varieties *muta* Walk., *subalpina* (Hudson) reduced from species rank, and *cutora* (Walker); *M. nigra**, *M. lindsayi**, and *M. iolanthe**, ♂ genitalia figured.

14821. PICKLES, ALAN. Leocomia cinchonae, sp. n., a new cercopid from Jamaica. *Ann. and Mag. Nat. Hist.* 6(35): 586-589. 2 fig. 1930.—*L.* **cinchonae*** (p. 586), host *Miconia rubens**, with notes on its biology. Nymphs of all stages (130) were dissected and examined for parasites, but with no success. Eggs, under observation for about one week, also failed to show signs of parasitism.

14822. SMITH, FLOYD F. A further comment on the "pumping" habit of plant lice. *Science* 73(1892): 364. 1931.—The writer, in his studies on feeding habits of certain leafhoppers and aphids, failed to discern any external evidence of "pumping" of sap by any of the species with their beaks in place. Insertion of the mouth-parts into the plant tissues and extraction of sap calls into play delicate muscles located within the head. External evidence of such muscular activity would be quite different from any violent "pumping" action.

14825. [ARNOLDI, K. V.] АРНОЛЬДИ, К. В. О представителях двух новых для Союза ССР триб муравьев-понерин. [Representatives of two tribes of Ponerinae, new to the USSR.] Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 24(3/4): 156-161. 4 fig. 1930.—Proceratiini: *Sysphincta europaea* ssp. **rossica*** (p. 157), Russia. **AULACOPONE** (p. 159), erected for *A.* **relicta*** (p. 159), Azerbaijan. **STICTOPONERINI** (p. 161), new subtribe in Ectatommini, erected to include *Aulacopone, Alfaria,* and *Stictoponera.*

14826. BECK, D. ELDEN. Bees of the sub-family Osminae in the collection of the Brigham Young University. *Bull. Brooklyn Ent. Soc.* 24(5): 303-306. 1929.—A list of 36 spp. with collecting records.

14827. BENGTSSON, SIMON. Humlor-Bombinae. 3. In: Insektfaunan inom Abisko Nationalpark. II. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* No. 17. pp. 1-3. 1931.—A list of 15 spp., with brief distributional notes.

14828. BENOIST, RAYMOND. Descriptions d'espèces nouvelles d'Hyménoptères mellifères du genre Heriades. *Bull. Mus. Nation. Hist. Nat. Paris* 1928(5): 332-336. 1928.—*Heriades* **tumida** ♂ (p. 332), *H.* **gibba** ♂ (p. 333), *H.* **forcipata** ♂ (p. 334), and *H.* **depauperata** ♀ (p. 334), Turkey; *H.* **syriaca** ♀ (p. 335), Syria. Types in Mus. Nation. Hist. Nat., Paris.

14829. BENOIST, RAYMOND. Les Quartinia (Hymen. Vespidae) de la région Méditerranéenne. *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 92-95. 2 fig. 1929.—Records of 6 spp., including *Quartinia* **lesnei** ♀* (p. 92), Algeria, type in Mus. de Paris; *Q.* **cincta*** (p. 93), Morocco.

14830. BENOIST, RAYMOND. Hyménoptères mellifères nouveaux du Maroc. *Bull. Soc. Sci. Nat. Maroc* 9(7/8): 120-121. 1929.—*Anthophora retusa* v. **seminigra** (p. 120); *A. balneorum* v. **africana** (p. 120); *A. b.* var. **subcarinata** (p. 120); *Rhophites* **theryi** (p. 120); *Osmia lamina* J. P. (=*O. triloba* Ben.).

14831. BENSON, ROBERT B. Nine sawflies requiring new names. *Entomologist* [*London*] 63(804): 107. 1930.—*Blennocampa* **dyari** (*B. spiraeae* Dyar, not Brischke); *Hemidianeura* **flavicornis** (*H. apicalis* Enderlein, not Mocsáry); *Monophadnus* **furvus** (*M. bipunctatus* MacGillivray, not Klug); *M.* **vapularis** (*M. planus* MacGill., not Klug); *Tenthredella* **viridans** (*T. enslini* Forsius, not Schirmer); *Tenthredo* **afra** (*T. diversipes* Pic, not Schrank); *T.* **lovetti** (*T. rustica* MacGill., not L.); *T.* **pallidula** (*T. albiventris* Mocsáry, not Klug); *T.* **variana** (*T. variabilis* Mocs., not Klug).

14832. BEQUAERT, J. Moroccan folded-winged wasps, mainly collected by Professor T. D. A. Cockerell's party. *Jour. New York Ent. Soc.* 39(2): 131-137. 1931.—Records of 4 spp. of Masaridinae, 9 Eumeninae, 2 Polistinae, and 2 Vespinae.

14833. BERLAND, LUCIEN. Les Sphegidae (Hyménoptères) du Muséum National de Paris. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(5); 329-331. 1928.—Locality records for 12 spp. of the subgenus *Sphex* and their varieties. *Sphex umbrosus* v. **aureopilosa** (p. 330), Tonkin, Kiang Si, and Ceylon; *S. luctuosus* v. **splendida** (p. 331), Loyalty Isls.

14834. BISCHOFF, H. Eine bisher verkannte und eine neue Art der Gattung Vespa aus der mitteleuropäischen Fauna. (Hym. Vesp.). *Mitteil. Deutschen Ent. Ges.* 2(1): 6-7. 1931.—*Vespa* **adulterina** (*V. norvegica* var. *a.*

Buyss.) (p. 6); *V.* **omissa** (p. 6), Thuringia, type in Zool. Mus., Berlin.

14835. BISCHOFF, H. Was ist Vespa tripunctata Schenck (1861)? *Mitteil. Deutsch. Ent. Ges.* 2(5): 66. 1931.—*Pseudovespa omissa* Bischoff (=*Vespa tripunctata* Schck., not Fab.).

14836. CAVRO, E. Description d'un Cynipide [Hym.] nouveau de France. *Bull. Soc. Ent. France* 1928(11): 184. 1928.—*Eucoela* **cavroi** Hedicke.—*S. B. Fracker.*

14837. COCKERELL, T. D. A. The bees of Australia. (Cont'd from vol. 6, part iii, p. 236.) *Australian Zool.* 7(1): 34-54. 1931.—Records of Australian bees of the families Anthophoridae, Nomadidae, Melectidae, Andrenidae (subfam. Nomiinae). *Anthophora,* key to spp. in 2 groups; *Crocisa,* key to spp. in 2 groups; *Nomia,* key to spp.

14838. CUSHMAN, R. A. Three new Braconidae parasitic on bark beetles. *Jour. Wash. Acad. Sci.* 21(13): 301-304. 1931.—*Meteorus* **hypophloei** (p. 302), Washington, host *Hypophloeus* sp.; *Coeloides* **dendroctoni** (p. 303), Montana (type), Idaho, Washington, hosts *Dendroctonus monticolae* and *Ips oregoni; C.* **scolyti** (p. 303), Washington (type), Oregon, California, host *Scolytus* spp. Types in U. S. National Mus.—*R. A. Cushman.*

14839. CUSHMAN, R. A. Descriptions of thirteen new American and Asiatic ichneumon-flies, with taxonomic notes. *Proc. U. S. Nation. Mus.* 79(14): 1-16. 1931. —*Ectopimorpha* **luperinae** (p. 1), Iowa, host *Luperina stipata; Photocryptus,* contrasted with *Acroricnus; P.* **pachymenae** (*Cryptanura* (?) *p.* Cresson), host *Sceliphron fistularae,* and *P.* **ater** (p. 4), Canal Zone; *Calliephialtes* **nucicola** (p. 5), California (type), Oregon, and New Mexico, hosts *Carpocapsa pomonella,* in walnuts, and *Walshia amorphella; Calliephialtes* **benefactor** (p. 6), New Jersey, host *Grapholitha molesta; Eiphosoma aztecum,* emendation; *E.* **paraguaiense** (p. 7), Paraguay; *E.* **batatae** (p. 8), Brazil, host lepidopteron on sweet potato; *Capitonius* Brullé (=*Aulacodes* Cresson), emendation; *Helconidea* **necydalidis** (p. 10), British Columbia, host *Necydalis laevicollis; Chelonus* (*Chelonella*) **pectinophorae** (p. 11), Korea, host *Pectinophora gossypiella; Fornicia* **pilosa** (p. 12), Costa Rica; *Vipio* **chinensis** (p. 13), China; *Atanycolus* **anocomidis** (p. 14), Brit. Columbia, host *Anocomis lignea; Microbracon* **nigrorufum** (p. 15) and *M.* **isomera** (p. 16), Korea, parasites of *Pectinophora gossypiella.* Types in U. S. Nat. Mus.

14840. De GANT, FRANK D. A new species of Macrocentrus from Ohio (Hymenoptera: Braconidae). *Proc. Ent. Soc. Washington* 32(4): 65. 1930.—*M.* **pallisteri** ♀ (p. 65), Ohio, type in U. S. Nation. Mus.

14841. DODD, ALAN P. A revision of the Australian Teleasinae. *Proc. Linnean Soc. N. S. Wales* 55(2): 41-91. 1930.—Key to genera; *Trimorus* Forster (=*Hoplogryon* Ashm.); *Trimorus,* key to 60 spp.; *T.* **tenuistriatus** ♀ (p. 46), South Australia, type in S. Australian Mus.; *T.* **parvulinus** ♀ (p. 47), Victoria; *T.* **tantillus** ♀ (p. 48), Tasmania, type in S. Australian Mus.; *T.* **lativentris** ♀ (p. 48), S. Queensland; *T.* **parvipennis** ♀ (p. 49), Victoria; *T.* **citreiclavus** ♀ (p. 49), *T.* **tricoloricornis** ♀ (p. 50), and *T.* **pallidiclavus** ♀ (p. 51), Queensland; *T.* **nigrinotum** (*Pentacantha n.* Dodd) (p. 53); *T.* **striatiscutum** ♀ (p. 54), N. Queensland; *T.* **aterrimus** ♀ (p. 55), N. S. Wales; *T.* **australicus** (*Pentacantha australica* Dodd) (p. 56); *T. varicornis* Dodd (=*H. bicolor* Dodd) (p. 56); *T.* **bicoloricornis** ♀ (p. 57), Queensland; *T.* **atripes** (*T. nigripes* Dodd) (p. 58); *T. assimilis* Dodd (=*T. auratus* Dodd, *T. leai* Dodd); *T. punctatus* (=*T. niger* Dodd, *T. nigrellus* Dodd) (p. 61); *T.* **concoloricornis** ♀ (p. 62), Queensland; *T.* **breviventris** (p. 62), S. Queensland and Victoria; *T.* **striatellus** ♀ (p. 63), *T.* **novispinus** ♀ (p. 64), *T.* **pilosicornis** (p. 66), *T.* **delicatus** (p. 67), *T.* **impressus** ♀ (p. 68), *T.* **acutispinus** (p. 69), Queensland; *T.* **crassispinus** (p. 71), *T.* **validispinus** ♀ (p. 72), *T.* **tenuipunctatus** (p. 73), and *T.* **condensus** (p. 75), all Queensland; *T.* **latispinus** ♀ (p. 76), Victoria; *Trissacantha* Ashmead (=*Propentacantha* Kieffer, *Pentacantha* Ashm.), key to spp.; *T.* **asperata** (p. 81), *T.* **trifurcata** ♂ (p. 83), and *T.* **simulata** ♂ (p. 83), Queensland; *Gryonella,* key to spp.; *G.* **affinis** ♀ (p. 86), N. S. Wales; *G.* **magnidens** ♀ (p. 87) and *G.* **platythorax** ♀ (p. 88), Queensland; *Xenomerus,* key to spp.; *X. varipes* Dodd (=*X. dubius* Dodd). Types in Queensland Mus. unless otherwise stated. Redescriptions of all previously described species are given.

14842. DONISTHORPE, HORACE. Camponotus (Tanaemyrmex) britteni, sp. n. (Hymenoptera, Formicidae), a formicine ant new to science. *Ann. and Mag. Nat. Hist.* 8(43): 129-131. 1931.—*C.* (*T.*) **britteni** ♀ major and minor, England, types in Brit. Mus.

14843. DOZIER, H. L., and H. G. BUTLER. Notes on the rearing of Ascogaster carpocapsae, a braconid parasite of the codling moth. *Jour. Econ. Ent.* 22(6): 954-957. 1929.—*Ascogaster* oviposits in the eggs of the moth. The host larvae spins its cocoon but fails to pupate. Adult parasites emerged 17.3 days after the host stopped feeding. The total development of the parasite required 36.43 days.—*W. V. Balduf.*

14844. DULAC, ALBERT. Liste de Sphegidae et de Pompilidae des environs du Creusot. *Soc. Hist. Nat. d'Autun, Bull.* 29(3): 148-150. 1930.—Distributional list of 435 spp. of Sphegidae and 10 Pompilidae.

14845. ELLIOTT, E. A. New Stephanidae from Peru. *Entomologist* 64(816): 97-98. 1931.—*Stephanus* **testaceipes** ♂ (p. 97) and *Hemistephanus* **carinatus** ♀ (p. 97), types in Brit. Mus.

14846. FLANDERS, STANLEY E. The temperature relationships of Trichogramma minutum as a basis for racial segregation. *Hilgardia* 5(12): 395-406. 4 fig. 1931. —There are at least 4 races of *T. minutum* that can be differentiated by color when reared at identical temp., but at certain dissimilar temp. they can not be separated. A yellow race from Massachusetts is less responsive to variations in temp., has a shorter life cycle and develops in a normal manner at a higher temp. than the dark race from tropical Mexico. The amount of pigmentation in the adult is determined by the duration of exposure to low temp. during the early pupal period. The slowing up of development by exposure to low temp. is most marked in the pupal stage.

14847. FLANDERS, STANLEY E. Races of Trichogramma minutum. *Pan-Pacific Ent.* 7(1): 20-21. 1930.— The strains from various localities in N. America are segregated according to color and life cycles into 5 races, which are briefly characterized.

14848. FORSIUS, RUNAR. A new Diprion from China. *Notulae Ent.* [*Helsingfors*] 11(1): 26-27. 1931.—*D.* **marshalli** ♀ (p. 26), type in Imp. Bur. Ent., London.

14849. FRISBY, G. E. The Hymenoptera of the Rochester district. *Rochester Nat.* 6(131): 90-101. 1928.—An annotated list of the Hymenoptera near Rochester (Kent, England).

14850. GAHAN, A. B. Two new hymenopterous parasites of Tachypterellus consors Dietz. *Jour. Washington Acad. Sci.* 21(3): 37-39. 1931.—*Habrocytus* **lividus** (p. 37) and *Entedon* **tachypterelli** (p. 38), Colorado; types in U. S. Nat. Mus.

14851. GAUTIER, CL., et S. BONNAMOUR. Remarques sur Ephedrus plagiator Nees [Hym. Braconidae]; complément de description de cette espèce. [Remarks on E. plagiator, with a description of the sp.] *Bull. Soc. Ent. France* 1929(5): 92-95. 1 fig. 1929.

14852. GAUTIER, CL., et S. BONNAMOUR. Description d'un nouvel Apanteles. *Bull. Soc. Ent. France* 1930 (5): 108-112. 1 fig. 1930.—*A.* **polypori*** (p. 108), a parasite of an unknown insect which feeds on *Polyporus hispidus* in France.—*S. B. Fracker.*

14853. GAUTIER, CL., et H. CLEU. Un Chelonus [Hym. Braconidae] parasite de la chenille d'Argyresthia chrysidella Peyer. [Lep. Tineidae.] *Bull. Soc. Ent. France* 1930(11): 196-198. 1930.—*Chelonus* **hiemalis, France,** parasitizing *A. chrysidella* in the fruits of *Juniperus oxycedrus.*—*S. B. Fracker.*

14854. HUNGERFORD, H. B. An unusual nest of

Vespula (Dolichovespula) arenaria Fabr. (=V. diabolica de Saussure). (Hym.: Vespidae.) *Ent. News* 41(10): 329-330. 1 pl. 1930.—As the nest* was built against a window, its internal structure is seen in cross section.

14855. KARAWAJEW, W. Beitrag zur Ameisenfauna Jakutiens. *Zool. Anz.* 94(3/4): 104-117. 2 fig. 1931.—This paper, based upon material collected by expeditions of the Russian Acad. Sci. in 1925-26, consists chiefly of detailed distributional data on 17 forms, with some remarks on taxonomy and ecology. *Myrmica bergi* v. divergens* ♀ (p. 105) and *M.* (*Myrmica*) forcipata* ♀ (p. 105), Yakutsk, Siberia.

14856. KOSTYLEV, GEORG. Drei neue Odynerus-Arten aus Turkestan (Hymenoptera). Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 23(1/2): 111-114. 2 fig. 1929.—*Odynerus* (*Lionotus*) sarykorum* ♀ (p. 111), Transcaspia; *O.* (*L.*) zhelochovtzevi* ♂ (p. 112) and *O.* (*L.*) edentatus* ♂ (p. 114), Turkestan.

14857. MARÉCHAL, PAUL. Sur trois Hyménoptères se développant dans un cocon en mosaïque. (Supplement.) *Mém. Soc. Ent. Belgique* 23(4): 163. 1930.—A correction and a few definite data on the ♂ and ♀ larvae of *Miscophus spurius* Dahlb.—*P. Maréchal.*

14858. MENOZZI, C. Raccolte mirmecologiche dell' Africa orientale conservate nel Museo Civico di Storia Naturale "Giacomo Doria" di Genova. Parte prima. Formiche raccolte dal Marchese Saverio Patrizi nella Somalia Italiana ed in alcune località dell' Africa orientale inglese. [Myrmecological collections from East Africa in the Mus. Civ. Genova. I. Ants collected by Saverio Patrizi in Italian Somaliland and in some localities of British E. Africa.] *Ann. Mus. Civ. Storia Nat. Genova* 52: 356-362. 3 fig. 1925/1928.—A record of 27 spp. of Formicidae, including *Carebara* patrizii ♂* (p. 357) and *Acantholepis* somalica (p. 359), types in Mus. Civ. Genova.

14859. MENOZZI, C. Risultati zoologici della missione inviata dalla R. Società Geografica Italiana per l'esplorazione dell' oasi di Giarabub (1926-1027). Formicidae (Hymenoptera). [Zoological results of the mission sent by the R. Soc. Geogr. Ital. for exploring the oasis of Jarabub. Formicidae.] *Ann. Mus. Civ. Storia Nat. Genova.* 52: 379-382. 1925/1928.—A list of 23 spp., with notes on occurrence. *Acantholepis frauenfeldi* v. *nigrescens* ♀, first description; *Cataglyphis albicans* ssp. *livida* v. *aurata*, ♀ (dealated), first description.

14860. MERCET, RICARDO GARCIA. Les genres Prochiloneurus et Achrysopophagus. (Hymen.-Chalcididae.) *Bull. Soc. Roy. Ent. Égypte* 14(4): 224-228. 2 fig. 1931.—These 2 genera are very close, and the only known hosts are spp. of *Pseudococcus. Achrysopophagus,* key to spp.; *A.* aegyptiacus ♀* (p. 225), Egypt, type in Alfieri coll.

14861. MÜLLER, MAX. Unsere Pillenwespe (Eumenes F.). *Mitteil. Deutsch. Ent. Ges.* 2(5): 70-75. 1931.—Notes on the nesting habits and developmental stages of *Eumenes coarctatus* and *E. pomiformis.* The enemies are *Chrysis ignita, Mesostenus gladiator,* and *Acroricnus stylator.*

14862. NOVICKY, SVATOSLAV. On two chalcidoid parasites of Zeuzera pyrina L. Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 23(1,2): 32-36. 5 fig. 1929.—*Elasmus* ciopkaloi* (p. 32) and *Euderus* sp.*, Ukraine.

14863. PATE, V. S. L. A new Belomicrus from the west. (Hymen.: Sphecidae.) *Ent. News* 42(3): 77-78. 1931.—*B.* franciscus (p. 77), California, type in Cornell Univ.

14864. PIC, M. Nouvelles notes hyménoptérologiques. 1° Ichneumoniens. *Bull. Soc. Ent. France* 1929(19): 306-307. 1929.—These notes relate to the distribution in France of 8 spp. of Ichneumonidae and 7 of Tenthredinidae.—*S. B. Fracker.*

14865. PICARD, F. Note sur les Stizus et les Bembex [Hym. Sphegidae] de l'Hérault. *Bull. Soc. Ent. France* 1930(3): 41-43. 1930.—Notes on the distribution of 8 French spp. of *Bembex,* 1 *Sphecius,* and 9 *Stizus.*—*S. B. Fracker.*

14866. ROUBAUD, E. Caractère obligatoire de l'hibernation chez les reines de Vespides annuels. Consequences biologiques. [Obligatory nature of hibernation in queens of annual Vespidae. Biological consequences.] *Bull. Soc. Ent. France* 1929(4): 83-84. 1929.

14867. SCHOUTEDEN, H. Les genres congolais de Sphégides. *Rev. Zool. et Bot. Africaines* 20(1): 90-96. 1930.—A list of 32 genera of the family Sphegidae contained in Congo Mus., Tervueren.

14868. SCHWARZ, HERBERT F. A case of stylopization in a panurgid bee, Liopoeum submetallicum (Spinola). *Jour. New York Ent. Soc.* 39(1): 77-79. 1931.—This is the first record of stylopization in the genus *Liopoeum* and is based on a specimen from Chile.

14869. SMITH, W. W. Ants inhabiting Mount Egmont. *New Zealand Jour. Sci. & Tech.* 13(1): 45-47. 1 fig. 1931.—Notes on 17 spp. of ants taken in the Mount Egmont Forest Reserve, New Zealand. Also a short note on the feeding habits of *Hemideina megacephala* (Orthoptera).

14870. WATERSTON, JAMES. On the differential characters of Chelonogastra Ashmead and Philomacroploea Cameron, two genera of Ichneumon flies of the family Braconidae. *Proc. Ent. Soc. Washington* 31(8): 167-168. 1929.—The 2 genera are to be considered distinct.

14871. WELD, LEWIS H. Three new gall-flies from Arizona (Hymenoptera: Cynipidae). *Proc. Ent. Soc. Washington* 32(2): 28-31. 1930.—*Diplolepis* capronae ♀ (p. 29), *Andricus* scutella ♀ (p. 29), and *Xanthoteras* mediocre ♀ (p. 30), gall formers on *Quercus subturbinella.* Types in U. S. Nat. Mus.

14872. WHEELER, WILLIAM MORTON. A list of the known Chinese ants. *Peking Soc. Nat. Hist. Bull.* 5(1): 53-81. 1930.—This list records 245 forms, comprising 138 species, 54 subspecies, and 53 varieties.

MACROLEPIDOPTERA

J. McDUNNOUGH, *Editor*

(See also in this issue Entries 12150, 12621, 12628, 13846, 13855, 13857, 13870, 13941, 13944, 14672, 14673, 14677, 14680, 14685, 14902, 14907, 15082)

14873. CLAYHILLS, THOMAS H. Eine neue Noctuiden-Art aus Nord-Europa. *Notulae Ent.* [*Helsingfors*] 10 (3): 80-82. 1 pl., 1 fig. 1930.—*Rhyacia* fennoscandica* (p. 80), N. Finland and N. Sweden.

14874. COLLENETTE, C. L. Lymantriidae (Lepidoptera Heterocera) from N. E. (British) Somaliland. *Ann. and Mag. Nat. Hist.* 7(39): 286-289. 1931.—First record for Somaliland of *Naroma signifera, Laelia subrosea,* and *Lymantria modesta; L.* finitorum ♀ (p. 289); *Laelia* somalica (p. 288). Types in Brit. Mus.

14875. COMSTOCK, JOHN A. Studies in Pacific Coast Lepidoptera (continued). *Bull. Southern California Acad. Sci.* 29(3): 135-142. 2 pl., 3 fig. 1930.—Description of early stages (egg, larva, or pupa) of *Parnassius smintheus behrii*, *Phyciodes campestris*, *Prenes errans*, and *Platysamia gloveri** with notes on food plants.

14876. DUMONT, C. Expériences sur la modification profonde du régime alimentaire de diverses chenilles. *Ann. Soc. Ent. France* 97(1/2): 59-104. 1928.—Caterpillars, fed on carrots, showed every degree of adjustability in taste, and in physiological effect. In 210 spp. of 109 genera and 25 families, there was at least partial success, the largest numbers being: 68 Noctuidae (with 8 each of *Agrotis* and *Mamestra*), 57 Geometridae (with 11 *Larentia* and 7 *Boarmia*), 11 Arctiidae, 6 Lymantriidae, 13 butterflies and 34 microlepidoptera. Only 18 spp.

refused the food entirely; 94 tried the food but soon succumbed; 33 more failed to pupate (full discussion of *Cossus cossus*); 24 died in the pupa; and about 52 survived the experiments. Of the last 28 were normal, 4 dwarfed, 12 pauperized and albinic, and 9 melanic; 2 spp., both melanic, had a quickened life history, and 3 (1 of them pauperized) showed delayed development.—*W. T. M. Forbes.*

14877. **GIACOMELLI, EUGENIO.** Sobre una rara especie de Euptoëta (Rhopalocera, Nymphalidae). *Rev. Soc. Ent. Argentina* 1(2) 39-40. 1 fig. 1926.—*E.* ramirezi* (p. 39), Argentina, type (♂ ?) in author's coll.

14878. **GUNDER, J. D.** Butterflies of Los Angeles County, California. Being an annotated check list giving details of where to go, when to go, and what to collect. *Bull. Southern California Acad. Sci.* 29(2): 39-95. Map, 5 pl., 2 fig. 1930.—With the cooperation of several local lepidopterists (whose portraits appear in a plate), the author gives an annotated list of 178 forms of Rhopalocera, including the original reference of the technical names, the common names, references to published illustrations, detailed records of localities and dates, and food plants. Three new "transition forms" are described: *Eurema nicippe* tr. f. dammersi* ♀ (p. 52), type in author's coll.; *Melitaea wrightii* tr. f. pelona ♀ (p. 61), type in coll. of J. A. Comstock; *Phyciodes mylitta* tr. f. collinsi ♂ (p. 62), type in author's coll. A map shows collecting localities.

14879. **HOLLAND, W. J.** New species of Erebia (Lepidoptera: Satyridae). *Trans. Amer. Ent. Soc.* 56(3): 149-153. 1930.—*E.* avinoffi (p. 151) and *E.* steckeri (p. 153), Alaska. These spp. will be illustrated in the new edition of the Butterfly Book.

14880. **JOICEY, J. J., and G. TALBOT.** A catalogue of the Lepidoptera of Hainan (China). *Bull. Hill Mus.* [*London*] [Continuation.] 3(3): 151-162. 1929.—A complete list of spp. known to occur on Hainan. The present paper treats Erycinidae (5 spp.) and Lycaenidae (63 spp.). *Curetis acuta* and *C. paracuta* are distinct spp. 28 spp. in these families are recorded for the 1st time from Hainan.—*J. J. Joicey.*

14881. **HENIG, BLUMA.** Über die Chordotonalorgane der Schmetterlingsraupen. *Zool. Anz.* 89(5/6): 183-186. 1 fig. 1930.—A chordotonal organ occurs in the femur of all 3 pairs of legs of the butterfly larvae of *Orthosia lota* Cl. and *Sylepta ruralis* Sc. The organ consists of 8-10 characteristic sensory nerve cells lying in the proximal region of the femur. The organs may be considered "typical chordotonal organs of the leg" as designated by Eggers. The absence of a proximal insertion and the double distal insertion point are characteristic.—*B. Henig* (*transl. by W. P. Hayes*).

14882. **KOZHANTSHIKOV, IGOR.** Uebersicht der Gattung Dichagyris Ld. (Lepidoptera, Noctuidae). Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 24(1/2): 1-30. 5 pl. 1930.—The paper is based on material from Zool. Mus. Acad. Sci. Leningrad, Inst. of Comp. Zool. and Phytopathol., and Tiflis Mus. Keys are given to ♂♂ and ♀♀ of *Dichagyris*, and one for determination of the spp. by the markings. Nineteen spp. are discussed, including: *D.* jacobsoni ♂* (p. 5), Transcaspia; *D.* assimilata ♂* (p. 7), Caucasus; *D.* armeniaca ♂* (p. 7), Armenia; *D. tyrannus* striatus (p. 10), Persia; *D. squalidior* albicolaris (p. 11), Caucasus; *D.* nigrolineata* (p. 11), Persia; *D.* crimaea* (p. 13), Crimea; *D.* subsqualorum* (p. 14), Caucasus; *D.* venosa* (p. 16), *D.* bisignata* (Tshetverikov in litt.) (p. 17), and *D.* melanuroides* ♂ (p. 18), Turkestan.

14883. **NITSCHE, JOSEF.** Zur Fauna des Grossen und Kleinen Fleisstales in Kärnten. *Verhandl. Zool.-Bot. Ges. Wien* 79(2/4): (92)-(98). 1929(1930).—Numerous local records of Lepidoptera, including *Larentia aptata* ab. stenotaeniata (p. 97).

14884. **PATTERSON, S. C.** List of Lepidoptera of Whangarei. *Trans. and Proc. New Zealand Inst.* 61 (3/4): 554-561. 1930.—About 250 spp. are listed, with notes on status, seasonal occurrence, and habitat.

14885. **PREISS, J.** Die Schmetterlingsfauna des unteren Werratals. (Macrolepidoptera.) *Abhandl. u. Ber. Vereins Naturk.* (*e. V.*) *Kassel* 57: 20-27. 1929.—Faunistic, ecological and life history notes on a large number of families and spp., including ecological notes on the region.

14886. **PROUT, LOUIS B.** A list of the Geometridae collected by Mr. C. L. Collenette in British Somaliland, with descriptions of new species. *Ann. and Mag. Nat. Hist.* 7(39): 262-272. 1931.—*Scopula* nephotropa ♀ (p. 263); *Zygophyxia* transmeata ♀ (p. 263); *Eupithecia* profuga ♀ (p. 264); *Coenina* collenettei ♂ (p. 265); *Sesquialtera* audens ♀ (p. 266); *Epigynopteryx* lioloma (p. 267); *Psilocerea* hypermetra ♀ (p. 267); *Ectropis* oleitincta ♀ (p. 268); *Boarmia* syntropha (p. 269); AËTHEOMETRA (p. 271), related to *Atomorpha*, type *A.* iconoclasis ♂ (p. 271); *Zamarada consecuta* ssp. mesotaenia (p. 272).

14887. **REBEL, HANS.** Kongo-Lepidopteren, gesammelt von Weidholz 1927/28. *Verhandl. Zool.-Bot. Ges. Wien* 79(2/4): (98)-(103). 1929(1930).—An annotated list of about 87 forms from French Equatorial Africa and the Belgian Congo, including *Pieris theora* ssp. weidholzi ♂ (p.(99)), Belgian Congo, type in Naturhist. Mus. Vienna.

14888. **SCHAWERDA, KARL.** Neue Lepidopteren aus Aragonien. *Zeitschr. Österreich. Ent.-Ver.* 12(4): 35-37. 1927.—*Satyrus prieuri* v. *iberica* ab. fumosa (p. 35); *Acidalia marginepunctata* ab. zernyi (p. 36); *Lithina convergata* ab. carmen (p. 36), type in author's coll.; *Selidosema plumaria* ab. aragonensis (p. 36); *Axia margarita* v. soledad (p. 36), and ab. rubrociliata (p. 37), type in author's coll.; *Lithosia* predotae (p. 37), type in author's coll.

14889. **SCHULTZE, ARNOLD.** Biologisches aus dem afrikanischen Aequatorialwald. *Deutsche Ent. Zeitschr. "Iris"* 44(4): 176-188. 2 pl., 4 fig. 1930.—Notes on some Lepidoptera spp., including *Papilio ridleyanus* ab. semivitreus (p. 176), "Mongoumba"; *Salamis cacta* ♂*, *S. parhassus**, *Cymothoe theobene**, and *Acanthosphinx güssfeldti** are figured.

14890. **STICHEL, H.** Eine neue Hamearisart. *Rev. Soc. Ent. Argentina* 1(1): 12-13. 1926.—*H.* hubrichi (p. 12), type in Bruch coll.

14891. **TURATI, EMILIO, e ATTILIO FIORI.** Lepidotteri di Rodi. [Lepidoptera of Rhodes.] *Mem. Soc. Ent. Ital.* 9(2): 196-214. 1930.—A list of 126 forms, with locality records and taxonomic remarks. *Aporia crataegi* f. fert (p. 197); *Gonepteryx cleopatra* f. fiorii (p. 199); *Epinephele cypricola* f. ornata (p. 201); *E. rhamnusia* f. lupinulus ♂ (p. 202); *Lycaena loewii* f. robusta (p. 204); *L. cyllarus* f. insulicola (p. 204); *Stenoptilia* stenodactyla (p. 210); *Glyphipteryx* medianella ♀ (p. 211); *Rhinosia* ochracella ♀ (p. 212); *Peritia* cinereipunctella (p. 213).

14892. **TURNER, A.** Revision of Australian Oenochromidae (Lepidoptera). III. *Proc. Linn. Soc. N. S. Wales* 55(3): 191-220. 1930.—47 spp., with synonymies, descriptions, and distributional records are treated. Keys to the spp. of *Oenochroma, Gerusia, Eumelea, Zeuctophlebia, Derambila* and *Ozola* are given. *Oenochroma* alpina ♀ (p. 196), N. S. Wales, type in coll. Goldfinch; *Monoctenia punctiunculus* Luc., emended to *Antictenia punctiulis; Gerusia* rubricosa ♀ (p. 203), Queensland, type in coll. Barnard; *Eumelea* stipata (*E. rosalia* f. *stipata* Prout) (p. 208); AXIAGASTA (p. 209), allied to *Zeuctophlebia*, erected for *A.* rhodobaphes (p. 210), Queensland; *Noreia vinacea* Prout (=*Idiodes loxosticha* Turner); *Derambila* idiosceles (p. 215), N. Australia and Queensland; *D.* liosceles ♂ (p. 216), Queensland and Timor. The following spp. have been wrongly referred to the Oenochromidae: *Aspilates chordota* Meyr. (Boarmiadae); *Arhodia orthotoma* Low., a synonym of *Orsonota clelia* Cram. (Boarmiadae); *Arhodia porphyropa* Low. (Geometridae); *Monoctenia niphosema* (Noctuidae). *Dichromodes* ? *triglypta* Low. belongs in *Sterrha; Epidesmia unilinea* Swin., is a synonym of *Heteralex aspersa* Warr., the type being from China, not Tasmania.

14893. **WAGNER, FRITZ.** Berichtigung zu meinem Artikel: "Ueber einige neue und wenig bekannte Lepidopteren aus Spanien." *Zeitschr. Österreich. Ent.-Ver.* 12(4): 40. 1927.—*Larentia euphrasiata* Millière (=*L. flavoparsata* Wgnr.); *L. brunnescens* [?] Kit (=*L. galiata* v. *ochreata* Wgnr.).

14894. **WARNECKE, G.** Lampropteryx (Larentia) interponenda n. spec. Warn., eine neue Art der Lampr. suffumata Hb.-Gruppe (Lep. Geom.). *Internat. Ent. Zeitschr.* 24(34): 361-366. 1 pl., 4 fig. 1930.—*L.* (*Larentia*) interponenda* (p. 361), Koko-Nor, China, in Zool. Mus. Hamburg.

14895. **WHEELER, GEORGE.** Notes from the French Alps of Haute Savoie, Isère and the Hautes Alpes. *Ent. Record* 43(1): 1-5. 1 pl. 1931.—A list of spp. observed, with notes of frequency.

14896. **WILLIAMS, R. C. Jr., and E. L. BELL.** Short studies in American Hesperiidae. (Lepidoptera: Rhopalocera.) *Trans. Amer. Ent. Soc.* 56(2): 133-138. 1 pl., 1 fig. 1930.—Geographical range is given for *Pyrgus syrichtus* F. and *P. orcus* Cramer. *P. communis* Grote (=*Hesperia tessellata* Scudder). The ♂ genitalia of *Atrytonopsis lunus* Edwards are figured.

14897. **ZIKAN, J. F.** Copiopteryx virgo n. sp. *Rev. Soc. Ent. Argentina* 2(6): 335-336. 1 pl. 1929.—From Argentina, type in Nosswitz coll. (Buenos Aires).

MICROLEPIDOPTERA

CARL HEINRICH, *Editor*

(See also in this issue Entries 12621, 13855, 13858, 13866, 13872, 13881, 13885, 13888, 13891, 14673, 14876, 14881, 14891)

14898. **BRAUN, ANNETTE F.** Notes on Pterophoridae with description of a new Oidaemetophorus (Lepidoptera). *Canadian Ent.* 62(6): 122-124. 1930.—Notes on the larval feeding habits of *Platyptilia fragilis* in seed capsules of *Penstemon cyananthus* in Utah. The larvae of *Stenoptilia coloradensis* attack the center shoot of *Gentiana quinquefolia*, and occasionally *Sabatia* in Ohio, having one generation a year; injury, mature larva, and pupa are described. The larvae of *Adaina cinerascens* feed on the underside of leaves of *Balsamorrhiza sagittata* in Utah. *Oidaematophorus* **confusus** (p. 123), reared on *Baccharis pilularis*, California. Types in author's coll.

14899. **FILIPJEV, N.** Lepidopterologische Notizen. VII. Eine neue Tortricidengattung aus den Gebirgen des Ussurigebietes. Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS, Sér. A.*) 1930(14): 373-375. 3 fig. 1930.—**EURYDOXA** (p. 373), near *Cerace*, type *E.* **advena*** (p. 374), Ussuri, Siberia.

14900. **HEINRICH, CARL.** Notes on and descriptions of some American moths. *Proc. U. S. Nation. Mus.* 79 (13): 1-16. 7 pl. 1 fig. 1931.—*Galenara* **consimilis*** (p. 1), New Mexico, larvae defoliate *Pseudotsuga taxifolia; Epipyrops* **cucullata*** (p. 2), Haiti, ♂*, pupa*; genitalia of *E. barbariana* figured; *Diatraea* **considerata*** (p. 3), Mexico, host, sugar cane, *Saccharum officinarum; D. busckella* v. **rosa** (p. 4), Venezuela, larva bores in sugar cane; *Platytes* (?) **aenigmatica** ♀* (p. 4), larvae attack stems of *Cirsium; Aglossa* **furva*** (p. 5), Brit. Columbia; *Gymnandrosoma desotanum*, first description of ♂*; *Thiodia* **implicata** ♂ (p. 7), Washington; *Gretchena dulciana*, host plant *Alnus; Epinotia* **opposita*** (p. 7), Peru, larvae bore in stems of alfalfa (*Medicago*) and cowpeas (*Vigna*); *E.* **accessa*** (p. 9), Panama; *E.* **patriciana** ♂* (*Eucosma p.* Wals.) (p. 10); *E.* **lantana*** (*Crocidosema l.* Busck) (p. 10); *Crocidosema plebeiana**, ♀ genitalia figured; *Anchylopera* **brauni*** (p. 11), Ohio, larvae feed on leaves* of *Rhamnus lanceolata; Anchylopera spiraeifoliana*, rectification of type; *Satronia tantilla**, host *Pinus palustris*, redescribed; *Phaecasiophora* **inspersa** ♂ (p. 13), Florida; **TSINILLA** (p. 14), in Olethreutinae, type *T.* **lineana** (*Eucosma l.* Fern.), first description of ♂*, larva feeds on folded *Anona* leaves. Types in U. S. Nat. Mus.

14901. **PETERSEN, WILHELM.** Die Blattminierer-Gattungen Lithocolletis und Nepticula (Lep.). Teil II. Nepticula Z. *Stettiner Ent Zeit.* 91(1): 1-82. 3 pl., 16 fig. 1930.—This is mainly a review and reclassification of the palearctic spp. of *Nepticula*, based primarily on genitalic characters. Of 135-140 spp., nearly 100 are described. Material was largely collected by the author, especially at Reval, Berlin, Sätja (Linné's old estate near Upsala), the Riesengebirge and in England. There is a discussion of the chief variable characters in the genus. The simple uncus, subscaphium present, more complete venation, coarse scaling and cocoon in the mine are considered primitive. The black head is viewed as in general a modern specialization, frequently postglacial, and often confined to the ♂. The larvae always feed on members of a single family, usually of a single genus. Host families include Rosaceae, Betulaceae, Fagaceae (Cupuliferae), and Salicaceae. Practically all feed on woody plants. Comparisons are made with the very similar case of the genus *Lithocolletis*. The spp. are divided into eleven genitalic types, three of which are subdivided; and the ♂ genitalia of all the spp. studied are figured. *N. betulicola* v. **nanivora** (p. 61), on *Betula nana*, is new.—*W. T. M. Forbes.*

14902. **PHILPOTT, ALFRED.** Notes and descriptions of New Zealand Lepidoptera. *Trans. and Proc. New Zealand Inst.* 62(1): 26-36. 4 fig. 1931.—*Scidosema melinata* Feld (=*S. scariphota* Meyr.); *Epicroeis sublignalis*, ♂ described, new to New Zealand; *Crambus malacellus*, new to New Zealand; **TAWHITIA** (p. 27) (Crambidae), type *T.* **glaucophanes*** (*Tauroscopa g.* Meyr.); *T.* **leonina*** (p. 28), Takitimu Mts., type in Cawthron Inst.; *Tauroscopa gorgopis*, wings*; *Scoparia* **subita** (*Orocrambus subitus* Philp.) (p. 28); *S.* **contexta** (p. 28), Mt. Moltke; *S. gyrotoma* Meyr. (=*S. repercussa* Philp.); *Aglossa cuprealis*, new to New Zealand; *Gauna aegalis*, in Auckland Province; *Eucosma mochlophorana* Meyr. (=*Eucosma aphrias* Meyr., *Raumatia trimaculata* Philp.); *Eucosma fugitivana* Meyr. (=*Raumatia varia* Philp.); *Elachista* **stellata** ♂ (p. 31); *Scythris* **nigra** ♂ (p. 31), Mt. Maungatua; *Leptocroca* **aquilonaris** (p. 31); *L.* **lenita** ♂ (p. 32); *Gymnobathra* **aurata** (p. 32); *Trachypepla* **minuta** ♂ (p. 33); *Proteodes clarkei*, first description of ♀; *Carposina* **marginata** ♂ (p. 33); *Stathmopoda* **albimaculata** ♀ (p. 33); *Tanaoctena* **dubia** ♂ (p. 34); *Orthenches* **disparilis** ♂ (p. 34); *O. chartularia* Meyr. (=*O. nivalis* Philp.); *O. similis* Philp., distinct from *O. semifasciata* Philp.; *Archyala* **culta** ♂ (p. 35); *Tinea* **conspecta** ♂ (p. 35); *T. belonota* Meyr. (=*Gymnobathra zephyrana* Clarke); *Porina* **gourlayi** (p. 36). Types, unless otherwise stated, in Auckland Mus.

14903. **REISS, HUGO.** Zygaena F. *Internat. Ent. Zeitschr.* 23(46): 521-525. 1929.—*Z. cilicica* Burgeff (=*laphria* Herrich-Schaffer, *ledereri* Stgr. Rbl., *charon* var. ?Stgr.); *Z. laphria* Freyer, and *Z. filipendulae* ssp. *anodolitia* Reiss, from Akshehr, the latter being distinct from *cilicica-ledereri.—W. T. M. Forbes.*

14904. **SHELDON, W. G.** Notes on the nomenclature and variation of British species of the Peronea group of the Tortricidae. *Entomologist* 63(805): 121-124; (806): 148-151. 1 pl.; (807): 175-178; (808): 193-198; (809): 222-225; (810): 242-246; (811): 273-277. 1930; 64(812): 2-6; (813): 30-34; (814): 60-64; (815): 77-82; (816): 99-103; (817): 124-127. 1931.—*Rhacodia emargana* fs. **griseana** and **fuscana** (p. 122); *Peronea cristana* f. **albicapitana** (p. 148); *P. hastiana** fs. **rufistrigana** (p. 176), **albicapitana, plumbeostriana, plumbeofasciana** (p. 177), **nigrovittana, nigrostrigana, apiciana*, transapiciania*, argentana*, argenteostrigana, ustomaculana** (p. 178), al-

bicostana*, sagittana* (p. 193); *P. maccana* fs. suffusana and canescana (p. 223); *P. umbrana* fs. lamprana (p. 224) and brunneana (p. 225); *P. hyemana* fs. griseana and brunneana (p. 243); *P. sparsana* fs. *sparsana* Schiff (=*P. sponsana* Fab.) and haworthana (p. 245); *P. lipsiana* fs. costimaculana (p. 274) and griseana (p. 275); *P. rufana* fs. ochreostriana (p. 276), ochreana, and purpurana (p. 277); *P. variegana* fs. brunneana (p. 3), fuscana (p. 4), and argentana (p. 5); *Acleris caledoniana* f. rufimaculana (p. 77); *Dictyopteryx lorquiniana* f. flavana (p. 100); *Oxigrapha logiana* f. tripunctana (p. 103); *O. literana* fs. fulvana* (p. 125) and brunneana* (p. 126). Keys are given to the forms of many spp.

14905. **SLASTSHEVSKIJ, P. Zur Biologie von Phassus schamyl Chr. (Lepidoptera, Hepialidae).** *Rev. Russe Ent.* 23 (3/4): 189-199. 1 fig. 1929.—This supplements Schaposchnikov's data. The mating flight takes place at dusk and is a swinging flight in both sexes. The ♀ has a heavier flight in laying eggs and flies both at dusk and dawn. The eggs are broadcast, and average about 2000, with a maximum of 3720. The ♀ lives two weeks, laying most of its eggs the first days. The egg is white, later turning black and the stage lasts 19 days or less. The first stage larva makes a sand tube and is very lively, later it lives in a tube in the soil which it leaves readily. The food is varied, but typically consists of dead leaves in the first 4 stages, and of roots in later stages. It refused ferns and *Verbascum*, but did well on potatoes. The larva and mating are figured.—*W. T. M. Forbes.*

14906. **TONNOIR, A. L. Notes on Indian blepharocerid larvae and pupae with remarks on the morphology of blepharocerid larvae and pupae in general.** *Rec. Indian Mus.* 32 (2): 161-214. 58 fig. 1930.—An historical survey of the Indian spp. in which the identities of *Blepharocera indica* Brun. and *Philorus bionis* Aghr. are questioned. A list of the larvae and pupae obtained from different localities in India is given; larvae A*, B*, C Aghr. are redescribed; *Apistomyia* larvae L*, M*, N*, larvae and pupa O*, larvae P*; genus? (near *Apistomyia*) larva K*; *Blepharocera* larvae A*, D*, larvae and pupa E*, larvae F*, G*, H* (*B. indica* Brun.?); genus ? (near *Blepharocera*) larvae J*; genus? (near *Blepharocera* and *Philorus*) pupa Q*; **EULIPONEURA** (p. 176) with *E.* horai (p. 176), larvae and pupae I*; *Euliponeura?* larvae B*, larva C*; **HORAIA** (p. 193), type (described in addendum); *H.* montana* (p. 210), larvae and pupa R_1*, larvae R_2, R_3, R_4. Notes on the morphology and metamorphosis of the larvae and pupae of the Blepharoceridae are also included. Types of new genera and spp. in the Indian Mus. In the addendum appears: *Euliponeura* assamensis* ♂ (p. 207).—*S. Ribeiro.*

14907. **WAGNER, FRITZ. Zweiter Beitrag zur Lepidopteren-Fauna Inner-Anatoliens.** *Internat. Ent. Zeitschr.* 23 (48): 545-558. 1 pl. 1929. 24 (2): 16-22. 1930. —(Macrolepidoptera) Noctuidae: *Agrotis* (*Euxoa*) cortii* (p. 549); *A.* (*E.*) glabella ♂* (p. 551); *A.* costaevittata* (p. 551); *Nonagria geminipuncta* v. orientalis* (p. 553). (Microlepidoptera) Pyralidae: *Dattinia* (*Epizonora*) variabilis (p. 17), with fs. obscurior ♀ and albidior (p. 18). Oecophoridae: **CROSSOTOCERA** (p. 19), with *C.* wagnerella (p. 20). Coleophoridae: *Coleophora* pellicornella ♀ (p. 21). Types in Naturhist. Mus. Wien. Besides these, *Leucanitis caucasica, Saragossa siccanorum, Agrotis robiginosa, Earias insulana, Arctia spectabilis, Gymnancyla canella, Bactra robustana,* and *Tineola murariella* are new to Asia Minor. *Anaitis opificata* Ld. and *A. kawrigini* Chr. are not synonymous, but separate, valid spp.

ORTHOPTEROIDEA

14910. CAMPOS, FRANCISCO. El grillo (Gryllus assimilis Fabr.) [The cricket G. assimilis.] *Rev. Colegio Nac. Vicente Rocafuerte* [*Guayaquil*] 10(32/35): 7-11. 1 pl. 1928.—A biological account of this orthopteran, dealing briefly with its distribution over Ecuador (where it is found up to altitudes of 4000 m.), its nymphal stage, its behavior during the mating season, and stridulation. Its omnivorous feeding habits constitute a factor of economic importance during seasons of great abundance of the insect; allusion is also made to the danger to public health, since *G. assimilis* is the carrier of the nematode *Gordius gryllivorus*. Its periodic abundance in Ecuador appears to be correlated with the seasonal change, its general appearance being coincident with the approach of winter.—*C. Zeimet.*

14911. CAPRA, FELICE. Una nuova specie di Troglophilus d'Italia (Orth. Phasgonuridae). *Ann. Mus. Civ. Storia Nat. Genova* 52: 310-313. 1 fig. 1925/1928.—*Troglophilus* **andreinii** ♂* (p. 310), Italy, type in Mus. Civ. Storia Nat. Genova.

14912. CHOPARD, L. Biospeologica. LVI. Campagne spéologique de C. Bolivar et R. Jeannel dans l'Amérique du Nord (1928). 8. Insectes Orthoptères. *Arch. Zool. et Gén.* 71(3): 389-402. 20 fig. 1931.—The evolution, phylogeny, and taxonomy of American cavernicolous Orthoptera are discussed; and the species are described in detail. Gryllacridae: *Hadenoecus subterraneus**, *H. puteanus**, *Ceuthophilus stygius**. *C. brevipes* is new to Kentucky.

14913. CHOPARD, L. Les Orthoptères du mont Aigoual. *Bull. Soc. Ent. France* 1930(7): 137-140. 1930.—Twenty-six spp. are listed from this region in southeastern France. —*S. B. Fracker.*

14914. CHOPARD, L. Description d'un Mantide (Orth.) mimétique des Cicindèles du genre Tricondylus. *Bull. Soc. Ent. France* 1930(14): 229-232. 1 pl. 1930.—**TRICONDYLOMIMUS** (p. 229), erected for *T.* **coomani*** (p. 229), Tonkin.—*S. B. Fracker.*

14915. CHOPARD, L. Sur une espèce nouvelle du genre Eneoptera confondue avec l'E. surinamensis (Orth. Gryllidae). *Bull. Soc. Ent. France* 1931(1): 14-16. 1931. —*Eneoptera* **guyanensis*** from French Guiana.—*S. B. Fracker.*

14916. CHOPARD, L., H. H. KARNY, and C. WILLEMSE. Orthoptera Celebica Sarasiniana. I. Saltatoria. *Treubia* 12(suppl.): 1-273. Map. 112 fig. 1931.—Each of the 3 authors cited above treats independently (not as joint author) certain families included in the group Saltatoria, as follows: H. H. KARNY.—Introduction (pp. 1-3. Map); Tettigoniidae (pp. 4-140. 70 fig.); Gryllacridae (pp. 141-184. 18 fig.). Karny also translated into German the sections contributed by Chopard and Willemse. The introduction contains a map of Celebes and adjacent islands, and a key to the families of Saltatoria found therein. Tettigoniidae: A table is given showing distribution of the Celebesian spp. or near allies of Tettigoniidae and Gryllacridae in Sumatra, Java, Borneo, Philippines, Sunda Isls., Moluccas, Key Isls., Aru, New Guinea, and N. Australia. A key is given to the subfams. of Tettigoniidae, and keys are also given to the genera of each subfam. *Emmarota* is redescribed; *E.* celebica* (*Locusta* (*Phaneroptera*) *c.* De Haan) (p. 12); *Ducetia thymifolia**; *Elimaea inversa**; *Isopsera vaga**; *I.* **fissa*** (p. 19), Buru; *Phaula* **neglecta** ♂* (p. 22); *P. compressa**; *Casignota longipes** is compared with *C. loliifolia** and *Elbenia jacobsonii**; *Tapiena* **chelicerca** ♂* [*Casigneta chelicerca* by error? in fig. 14, p. 30] (p. 29); *Liotrachela* **taeniistyla** ♂* (p. 32); *Holochlora* **metazonalis** ♂* (p. 35); *H.* **sarasini** ♀* (p. 36); *H.* **mapanensis** ♂* (p. 38); *Psyra* **celebica** ♀ (p. 43); *Phygela* **latipennis** ♂* (p. 45); *Sasima bifurcata* ♂*; *Sasimella* **sarasinifolia** ♀* (p. 49). *Phyllomimus detersus* ♀*; **DIPLODONTOPUS** (p. 57) (Pterophyllinae), near *Phyllomimus*, based on *D.* **insolitus** ♂* (p. 59); **ACAULOPLACELLA** (p. 62) (Pterophyllinae), type *Acauloplax asiatica** Brunner v. W.; the type species is provisionally left in *Acauloplax*. **DIAPHLEBOPSIS** (p. 67) (Mecopodinae), near *Paradiaphlebus*, type *D.* **fissiceps** ♂* (p. 70); *Segestes* **celebensis** ♂* (p. 72); *Sexava karnyi**; *S. coriacea**; *Phisis* **buruana*** (p. 91), Buru Isl.; *P.* **leontopolites** (p. 92); *P.* **sarasini** ♀* (p. 92); *Hexacentrus unicolor**; *Mortoniellus* **digitatus*** (p. 100); *M.* **hamatus** ♂* (p. 101); *M. azuriventer**; *Xiphidion maculatum**; *X. longipenne**; *X. affine**; *Nicsara* **aethiops** ♀* (p. 116); *N.* **sarasini** ♀* (p. 119); *N. inferior**; *Anthracites* **discolateralis** ♀* (p. 124); *A.* **tibialis*** (p. 126); *A.* **humeralis** ♀* (p. 127); *Xestophrys horváthi**; *Pseudorhynchus minor**; *Euconocephalus mucro**; *E. brachyxiphus**; *E. gracilis**. Gryllacridae: *Gryllacris*, key to 17 forms; *G.* **maculiventris** ♀* (p. 144); *G.* **celebica** ♀* (p. 149); *G. helleri**; *G.* **sarasini** ♂* (p. 154); *G. bicornuta**; *G. sexpunctata* spp. **obscuripes** ♂* (p. 159); *G. inconspicua**; *G.* **brevistyla** ♂* (p. 162); *G.* **nodistyla** ♂* (p. 164); *G. voluptaria**; *G.* **libidinosa** ♀* (p. 171); *Neanias* **celebensis** ♀* (p. 174); *Rhaphidophora* **sarasini*** (p. 179). L. CHOPARD.—Achetidae and Gryllotalpidae (pp. 185-188): A list of 20 spp. is given including *Euaphonus* **atrifrons** ♀ (p. 188). C. WILLEMSE.—Acrididae (pp. 189-270): key to 6 subfams., also keys to genera in each subfam. **CELEBOMASTAX** (p. 203) (Eumastacinae), type *C.* **curiosa** ♀* (p. 204); *Mnesicles* **saussurei** (*Xanthomastax crassipes* Sauss.) (p. 206); *Phlaeoba* **abbreviata** ♂* (p. 212); *Heteropternis obscurella**; *H. respondens**; *Tagasta celebesica**; *Trigonopteryx* **celebesia*** (p. 230); *Oxyrrhepes* **celebesia*** (p. 234); **PARACRANAE** (p. 234) (Cyrtacanthacrinae), near *Oxya*, type *P.* **celebesia*** (p. 235); *Tauchira* **gracilis*** (p. 242); *Chitaura brachyptera**; **TAURACRIS** (p. 248) (Cyrtacanthacrinae), near *Chitaura*, type *T.* **flavo-lineata** ♀* (p. 248); *Mesambria maculipes**; *Alectorolophus speciosus**; *A. applicatus**; *A. unilobatus**; *Celebesia acuticerca**; *Traulia ferruginata**. Except where otherwise given, new forms are from Celebes. All types in Wien Mus.

[São Paulo]* 1(3): 257-265. 6 fig. 1931.—Labiduridae, Psalinae: *Euborellia* **flavipes*** (p. 258); *E.* **inermis*** ♀ (p. 259); *Psalis* **brasiliensis*** ♂ (p. 260), *P.* **minima*** ♂ (p. 261). Brachylabinae: *Nannisolabis* **punctulata*** (p. 261), with var. **rufa** (p. 262). Strongylopsalinae: *Strongylopsalis iheringi* Rehn (=*Labia castanea* C. Moreira). Types in Inst. Biol. Defesa Agric., Rio de Janeiro.

14925. REGEN, JOHANNES. Über den Aufbau der Stridulationslaute der saltatoren Orthopteren. *Akad. Wiss. Wien Math.-Naturwiss. Kl. Sitzungsber. 1 Abt.* 139(8/10): 539-544. 1930.—The stridulations of *Liogryllus campestris, Thamnotrizon apterus, Chorthippus parallelus,* and *Oecanthus pellucens* are classified according to the rhythm as recorded by an oscillograph.

14926. REHN, JAMES A. G. On the blattid genera Abrodiaeta Brunner (=Allacta Saussure and Zehntner) and Margattea Shelford (Orthoptera). *Trans. Amer. Ent. Soc.* 57(3): 297-304. 1 fig. 1931.—*Allacta* Saussure & Zehntner, having as its type *Abrodiaeta modesta* Brunner, is rediagnosed. *Margattea* Shelford, rediagnosed, is closely related to *Allacta.*

14927. RUNGS, C. Contribution à la détermination du nombre des générations annuelles du criquet pélerin Schistocerca gregaria Forsk. *Bull. Soc. Sci. Nat. Maroc* 10(1/6): 66-69. 1930.—There are at least 2 generations of *S. gregaria* in Morocco. The insects are attacked by the fungi *Beauveria densa, B. bassiama, B. globulifera,* and *Spicaria verticilloïdes.*

14928. SILVESTRI, F. Notes on Grylloblatta campodeiformis and a description of a new variety (Grylloblattidae). *Trans. Amer. Ent. Soc.* 57(3): 291-295. 1 pl., 1 fig. 1931.—*G. campodeiformis** v. **occidentalis** (p. 293), Washington State, type in author's coll. The Grylloblattidae should form a group of equal rank with Blattoidea and Isoptera. The type localities of *G. campodeiformis* and *G. c.* var. *occidentalis* are shown in photograph.

14929. STÄGER, ROB. Einige Notizen über Anechura bipunctata (Dermatopt.). *Ent. Zeitschr., Frankfurt a/M* 43(22): 271-273. 1930.—Biological notes.

14930. UVAROV, B. P. A new mantid from Baluchistan. *Ann. and Mag. Nat. Hist.* 8(46): 418-419. 1931.—*Microthespis* **evansi** ♂ (p. 419), type in Brit. Mus., is compared with *M. dmitrievi.* The distinction between *Microthespis* and *Rivetina* is discussed.

14931. UVAROV, B. P. Composition and origin of the palaearctic fauna of Orthoptera. *Congrès Internaton. Xe Zool. à Budapest 1927* Part 2. pp. 1516-1524. 1929.—Autochthonous elements of the Palaearctic fauna of Orthoptera belong to 2 main groups: (1) A tropical Tertiary fauna of damp habitat; (2) an Atlantic fauna of (a) forest and (b) dry rocky habitats. The following developments have taken place in the evolution of the fauna: (1) Invasion of the Angara fauna, which occupied all except the most southern parts of the region; (2) secondary progressive development of the autochthonous elements in the Mediterranean countries, with 2 main centers, Iberian and Anatolian, and subsequent migration of new faunistic elements northward; (3) formation, in response to climatic conditions, of the desert fauna out of the Atlantic elements in 2 main centers, northwestern African and Persian, and subsequent spreading of these elements northward; and (4) development of the peculiar alpine fauna in Central Asia out of the autochthonous tropical elements lifted up by the rising of the mountain ranges.—*B. F. Howell.*

14932. WILLEMSE, C. Orthoptera (Acridiidae) from Mangalum Island, Northwest Borneo. *Bull. Raffles Mus.* 5. [93.] 1 pl. 1931.—A list of 4 spp., including *Valanga nigricornis* ssp. **mangalumensis.**

14933. ZOLOTAREVSKY, B. N. Sur le comportement du Phymateus puniceus Bol. (Orth. Acrididae). *Bull. Soc. Ent. France* 1930(18): 283-286. 1 fig. 1930.—*P. puniceus** in Madagascar is unattractive as food for animals or man on account of its bad odor. The adults are solitary, but the nymphs are gregarious, migrating to new plants in single file.—*S. B. Fracker.*

SMALLER ORDERS OF INSECTA

[A new genus and three new species of Thysanoptera Heliothripinae, taken at Bahia.] *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 83-88. 1 pl. 1931.—Heliothripinae, key to genera; **HOODOTHRIPS** (p. 83), near *Parthenothrips,* type *H.* **neivai** ♀* (p. 84), on *Dahlia variabilis,* and Apocynaceae; *Heliothrips* **apicallis** ♀* (p. 86), on Boraginaceae; *H.* **ipomoeae** ♀* (p. 86), on *Ipomoea batatas.* Types in author's coll.

14935. BROWN, JAMES MEIKLE. Report on the Collembola collected by the Oxford University expedition to Lapland, 1930. *Ann. and Mag. Nat. Hist.* 8(43): 131-139. 5 fig. 1931.—The collection consists of 14 spp. on which collecting data are given. *Proisotoma* (*Isotomina*) **lapponica*** (p. 134); *P. minuta**.

14936. GALLARD, LUKE. The discovery of the eggs of Heterojapyx gallardi, Tillyard. *Australian Nat.* 8(5): 92. 1931.—A cluster of 25 eggs were found under ground in N. S. Wales, attended by ♀; in another case 15 young were found clustered about the mother, much as in the manner of the centipedes.

14937. [JOHN, O.] ИОН, О. И. Пузыреногие из Новгородской губернии. (Thysanoptera from the Novgorod Province.) Русское Энтомологическое Обозрение (*Rev. Russe d'Ent.*) 24(3/4): 218-219. 1930.—

An annotated list of 22 spp., including *Prosopothrips vejdovskyi* and *Haplothrips alpester*, new to the USSR, and 4 other spp. new to the district.

14938. **JORDAN, KARL.** Three new South American fleas. *Novitates Zool.* [*Tring*] 36(3): 311-316. 5 fig. 1931.—**CTENIDIOSOMUS** (p. 311), near *Stenoponia*, type *C.* **spillmanni*** ♀ (p. 311), Ecuador, from *Neomys* sp.; *Craneopsylla* **chiris*** (p. 313), Argentina, on *Phyllotis xanthopygus* [Muridae]; *C.* **tolmera** ♂* (p. 314), Ecuador, on *Neomys* sp.

14939. **KARNY, H. H.** Zur Systematik der Orthopteroiden Insekten. Zweiter Teil. *Treubia* 12(3/4): 431-461. 1930.—This article deals primarily with classification of the Order Copeognatha [Corrodentia], but considers other orders. Isoptera: **TERMOPSIDAE** (p. 432), new fam. name for Protermitidae Holmgren; **RHINOTERMITIDAE** (p. 432), new fam. name for Mesotermitidae Holmgren; **TERMITIDAE** (p. 432), new fam. name for Metatermitidae Holmgren. Copeognatha: key to suborders, families, subfamilies, and tribes; checklist to the genera in each group. Some of the group names given below are new but the author does not so indicate. The classification used is as follows: the suborder Permopsocida is divided into 4 families, Psocidiidae, Permopsocidae, **MARTYNOPSOCIDAE** (p. 453), based on **MARTYNOPSOCUS** (n. n. for *Dinopsocus* Martynov not Banks) (p. 446), and **NEUROSEMIDAE** (p. 434), including the subfamilies Neuroseminae, based on *Neurosema* McLachlan, and Calopsocinae, based on *Calopsocus* Hagen. The suborder Embiopsocida contains only the Delopteridae, in which is placed **LITHOPSOCUS** (p. 435), n. n. for *Lithentomum* Martynov not Scudder. The suborder Parapsocida contains the fams. Trogiidae and Amphientomidae. The fam. **TROGIIDAE** (p. 441), is divided into subfamilies Thylacinae, with tribes Thylacini and Udamolepidini; Empheriinae, with tribes Empheriini and Rhypsocini; Psoquillinae; Trogiinae, with tribes Trogiini and Lepinotini; Psyllipsocinae, with tribes Psyllipsocini, Archipsyllini and Allopsocini; Troctinae, with tribes Embidopsocini, Troctini and Pachytroctini; Electrentominae; Pseudopsocinae; Prionoglarinae and Archipsocinae. The family Amphientomidae is divided into subfamilies Perientominae, with tribes Perientomini, Echmepterygini and Echinopsocini; Lepidillinae; and Amphientominae, with tribes Cymatopsocini and Amphientomini. The suborder Eupsocida contains the remaining four families. **STENOPSOCIDAE** (p. 444) contains the subfamilies Callistopterinae, Propsocinae, Stenopsocinae, and Bertkauiinae. The family Psocidae contains the subfamilies Myopsocinae; Psocinae, with tribes Psocini and Hemipsocini; and Thyrsophorinae, with tribes Ischnopterygini and Thyrsophorini. The family **LACHESILLIDAE** (p. 439), n. n. for Caeciliidae Enderlein, preocc. in Amphibia, includes the subfamilies Ptiloneurinae; Elipsocinae; Reuterellinae; Dypsocinae; Xenopsocinae; **LACHESILLINAE** (p. 451), with the tribes Epipsocini and **LACHESILLINI** (p. 451), the latter including *Lachesilla* Westwood and containing among other genera *Caecilius* Curtis upon which Caeciliidae was founded. The family Peripsocidae Cockerell is redefined, and contains the subfamilies Neurostigminae and Peripsocinae.

14940. **MORISON, GUY D.** A new thripid (Thysanoptera) from South Australia. *Bull. Ent. Res.* [*London*] 22(2): 245-248. 3 fig. 1931.—*Hemianaphothrips* (*Anaphothrips*) **concinnus*** (p. 245), on *Leptospermum lanigerum*, compared with *H. tersus**. Type in Brit. Mus.

14941. **PETERS, HAROLD S.** A new biting louse (Mallophaga) from white-tailed deer. *Proc. Ent. Soc. Washington* 32(5): 76-79. 3 fig. 1930.—*Tricholipeurus* **virginianus*** (p. 76), parasite on *Odocoileus v. virginianus*, Pennsylvania (type, in U. S. Nat. Mus.), and from *O. v. texanus*, Texas.

14942. **PRIESNER, H.** Indomalayische Thysanopteren III. *Treubia* 12(3,4): 263-270. 1930.—*Gynaikothrips* **brevisetis** (p. 263), ♂, ♀, and larva, Luzon, Philippines, on *Conocephalus*; *G.* **piperis** (p. 265), ♂, ♀, and larva; *G.* **eugeniae** (p. 266), Kuala Lumpur, in leaf gall on *Eugenia*; *G.* **ficarius** (p. 267), Singapore, in leaf gall on *Ficus benjamina*; *G.* **retusae** ♀ (p. 269), Penang, Malacca, on *Ficus retusa*.

14943. **SCHÖTT, HARALD.** Hoppstjärtar-Collembola. 15. In: Insektfaunan inom Abisko Nationalpark [Sweden]. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. Pp. 69-72. 1931.—List of 21 spp. in 3 families, with brief locality notes.

14944. **TUXEN, S. L.** Über die dänischen Machilidae. *Ent. Meddel.* [*Copenhagen*] 16(7): 398-400. 1929; (8): 401-413. 10 fig. 1930.—Keys are given for both sexes of the 7 north-European species of *Petrobius* Leach. Two of these have been found in Denmark: *P. balticus** Stach, very common, and *P. oudemansi** Carp., only 3 females. Also mentioned from Denmark is *Lepismachilis notata** Stach, this species previously having erroneously been called *Machilis polypoda* L. in Denmark.—*S. L. Tuxen.*

14945. **TUXEN, S. L.** Einige Apterygoten aus Südeuropa nebst Beschreibung zwei neuer Arten von Thysanura. *Ent. Meddel.* [*Copenhagen*] 17(3): 219-227. 7 fig. 1930.—A list is given of Apterygota collected in Croatia and north Italy. *Campodea* **suensoni*** (p. 222) and *Japyx* **sinuosus*** (p. 223) are described together with a juvenile form* (?) of the latter.—*S. L. Tuxen.*

14946. **WATSON, J. R.** A new Haplothrips from Panama. *Florida Ent.* 15(1): 11-12. 1931.—*Haplothrips* **panamaensis** ♀ (p. 11), on pineapple introduced in shipment to Washington, D. C., from the Canal Zone. Type in author's coll.

14947. **WEBER, HERMANN.** Die Lebensgeschichte von Ectopsocus parvulus (Kolbe 1882). Ein Beitrag zur Kenntnis der einheimischen Copeognathen. *Zeitschr. Wiss. Zool.* 138(3): 457-486. 18 fig. 1931.—*E. parvulus* is found in greenhouses on various hostplants in association with the homopteran *Trialeurodes vaporariorum*; it feeds upon the sooty mold which develops on the droppings of white flies. They spin webs* under which they live in colony. Reproduction is by thelytoky, no ♂♂ being produced. Development is at optimum at 20° C., requiring 9 days for the egg stage, 17 days for the larva; there may be 12 generations a year. The ♀ genital organs*, embryonic egg-burster*, egg*, embryo*, larval stages*, and adult* are described.

FOSSIL INSECTA

F. M. CARPENTER, *Editor*

14948. **ALEXANDER, CHARLES P.** Crane-flies of the Baltic amber (Diptera). *Bernstein-Forschungen* (*Amber Studies*) 2. 1-135. 1 pl., 168 fig. 1931.—The types of most of the described species of Tipulidae fossil in amber have been examined and many are figured. Baltic amber was formed during the Lr. Oligocene. Superfam. Tipuloidea, key to families. Tanyderidae: *Macrochile*, recharacterized, is distinct from the recent *Protoplasa*. *M. spectrum**. Tipulidae, key to subfamilies, tribes, and subtribes, in amber. Tipulini, key to genera and subg.; *Macromastix bornhardti**; **ELECTROTIPULA** (p. 21), n. subg. in *Tipula*, type *T.* (*E.*) **pinetorum** (p. 22), type in Berlin Mus.; key to ♂♂ of spp. of subg. *Tipula*; *T. media**; *T.* **submedia*** (p. 26), *T.* **digitifera*** (p. 26) and *T.* **phoracantha*** (p. 27), types in Klebs coll.; *T.* **presliana*** (p. 27), *T.* **spinistyla*** (p. 30), *T.* **falco** (p. 30), *T.* **handlirschiana*** (p. 32) and *T.* **scudderiana*** (p. 32), types in Geol. Inst. Coll. Univ. Königsberg; *T.*

*major**, *T. graciosa**, *T.* (?) *eocenica**. Limoniini: key to genera; *Limonia* Meigen (=*Ataracta* Loew), key to spp.; *L.* **meunieri*** (p. 36) and *L.* **flagellata*** (p. 38), types in Klebs coll.; *L.* **lobata*** (*Dicranomyia l.* Meunier) (p. 37); *L.* **sinuata*** (*D. s.* Meun.) (p. 39); *L.* **graciosa** (*D. g.* Meun.) (p. 39); *Dicranoptycha* **electrina*** (p. 40), type in Geol. Inst.; *Thaumastoptera* **electra*** (p. 41), type in Fritsch coll.; the genus *Antocha* does not belong to amber fauna; *Helius* **pulcher*** (*Rhamphidia pulchra* Meun.=*Antocha succinea* Meun.). Hexatomini: key to genera; *Palaeopoecilostola* Meunier, recharacterized, is restored to generic rank, removed from *Lasiomastix*, key to spp.; the type is designated as *P.* **longicornis*** (*Lasiomastix l.* Meun.=*Limnophila robusta* Meun.) (p. 46); *P. l.* ssp. **parallela*** (p. 48), type in Geol. Inst.; *P.* **speciosa*** (*Limnophila s.* Meun.) (p. 48); *P.* **fastuosa*** (*L. f.* Meun.). *Tanysphyra* Loew is removed from synonymy with *Limnophila*, and restored to generic rank, type *T.* **meunieri*** (*Limnophila m.* Ckll., *L. gracilis* Loew preocc.). *Austrolimnophila* **elegantissima*** (*Limnophila* (*Dactylolabis*) *e.* Meun.); *Phyllolabis* **andréei*** (p. 52), type in Geol. Inst.; *Trichoneura* Loew (=*Sackeniella* Meun.), key to ♂♂; *T.* **gracilistylus*** (p. 57), type in Klebs coll.; **ELECTROLABIS** (p. 58), near *Dactylolabis*, type *E.* **extincta*** (p. 58), type in Klebs coll.; **IDIOLABIS** (p. 59), n. subg. in *Dactylolabis*, type *D.* (*I.*) **terebrella*** (p. 60), type in Klebs coll.; *D.* (*Dactylolabis*) **vetusta*** (p. 60), type in Klebs coll.; *Pseudolimnophila*, key to spp.; *P.* **loewiella*** (p. 63), n. nom. for *Limnophila* (*Dactylolabis*) *concinna maculata* Meun.; *P.* **vulcana*** (*Limnophila v.* Meun.) (p. 64); *P.* **timida*** (p. 65), type in Geol. Inst.; *P.* **producta*** (*Prionolabis p.* Meun.) (p. 66); *P.* **exigua** (*Prionolabis e.* Meun.) (p. 66); *P.* **pinicola*** (p. 67), type in Klebs coll.; *P.* **inculpata*** (p. 68), type in Geol. Inst.; *P.* **continuata*** (*Limnophila* (*Dactylolabis*) *c.* Meun.); *P.* **ambigua*** (p. 70), type in Klebs coll.; *Limnophila*, key to spp.; *L.* (*Phylidorea*) **servilis*** (p. 72), type in Geol. Inst.; *L.* **samlandica*** (p. 73) and *L.* **skwarrae*** (p. 74), types in Klebs coll.; **TANYMERA** (p. 75), a name proposed (with insufficient diagnosis of the genus) by Loew in 1850 for 4 unnamed spp., type *T.* **fritschi*** (p. 78), type in Fritsch coll.; key is given to spp. of *Tanymera*; *T.* **arguta*** (p. 76) and *T.* **terminans*** (p. 78), types in Geol. Inst.; *T.* **berendti*** (p. 79), type in Klebs coll.; *Pilaria*, key to spp.; *P.* **batheri*** (p. 81), type in Brit. Mus.; *P.* **elongata*** (*Limnophila e.* Meun.) (p. 81); *P.* **electrina*** (*Limnophila e.* Ckll. & Clark) (p. 82); *P.* **baltica*** (p. 82) and *Hexatoma* **minuta*** (p. 84), types in Geol. Inst.; *Eriocera*, key to spp.; *E.* **plastica*** (p. 86), type in Brit. Mus.; *Elephantomyia* **baltica*** (p. 88), type in Klebs coll.; *Adelphomyia* **hirtipennis*** (*Ula h.* Meun.) (p. 93); *Tricyphona*, key to spp.; *T.* **succinea*** (p. 94), type in Klebs coll.; *T.* **sepulchralis*** (p. 94), type in Geol. Inst.; *T.* **electrina*** (p. 95), type in Zool. Mus. Eriopterini, key to genera and subg.: *Dasymolophilus* **circumcinctus*** (*Erioptera circumcincta* Meun.) (p. 98); *Ormosia* Rond. (=*Rhypholophus* Kol., *Gonomyiella* Meun.); *O.* **skwarrae*** (p. 100), type in Klebs coll.; *O.* **electrella*** (p. 101), *O.* **tornquisti*** (p. 102) and *O.* **beurleni*** (p. 102), types in Geol. Inst. *Erioptera*, subg. *Erioptera*, key to spp.; *E.* (*E.*) **arcuata*** (p. 105), type in Klebs coll.; subg. *Empeda*, key to spp.; *E.* (*Emp.*) *minuta** Meun. (=*E. prolifica* Meun., *E. elongata* Meun.); *E.* (*Emp.*) **platyphylla*** (p. 107), *E.* (*Emp.*) **duplicata*** (p. 108) and *E.* (*Emp.*) **axillaris*** (p. 110), types in Klebs coll.; *E.* (*Emp.*) **diacantha*** (p. 109), *E.* (*Emp.*) **subabortiva*** (p. 110) and *E.* (*Emp.*) **rectistyla*** (p. 111), types in Geol. Inst.; *Palaeogonomyia* Meun. is removed from *Gonomyia* and recognized as a subg. of *Rhabdomastix*, with type now designated as *R.* (*P.*) **pulcherrima*** (*Gonomyia* (*P.*) *p.* Meun.) (p. 114); *R.* (*P.*) **klebsi*** (p. 113), type in Klebs coll.; *R.* (*P.*) **elegantula*** (*G.* (*P.*) *e.* Meun.) (p. 114); *R.* (*P.*) *pulcherrima* **graciosa** (*G.* (*P.*) *g.* Meun.) (p. 116); *R.* (*P.*) **borussica*** (*G.* (*P.*) *b.* Meun.) (p. 117); *R.* (*P.*) **brevis*** (p. 117), type in Geol. Inst.; **ELECTROGONOMYIA** (p. 118), n. subg. in *Gonomyia*, type *G.* (*E.*) **pinetorum*** (p. 118), type in Klebs coll.; *G.* (*Gonomyia*) **oligocenica*** (p. 119), type in Geol. Inst.; *Gnophomyia*, key to spp.; *G.* **minuta*** (*Trimicra m.* Meun.) (p. 121); *G.* **inferna*** (p. 122) and *G.* **parvicellula*** (p. 122), types in Klebs coll.; *Trentepohlia* (*T.*) **dampfiana*** (p. 123). Other amber species are described and figured. The bibliography contains 42 references.

PROCHORDATA

(See also in B. A. 6(3): Entry 9061; 6(4): 11441; and in this issue 14475)

14949. **HARANT, HERVÉ.** Les ascidies et leurs parasites. *Ann. Inst. Océanograph.* 8(4): 231-389. Map, 60 fig. 1931.—A few new facts are brought out in this work, which completes and summarizes the author's publications since 1922. They are as follows.—Polyclinidae: **PSEUDODISTOMINAE** (p. 246), n. subfam. erected to include *Pseudodistoma, Homeodistoma,* **RITTERELLA** (p. 268) (n. n. for *Amaroucium aequalisiphonis* Ritter), and *Placentela; Polyclinum aurantium** Edw., recharacterized; *P. a.* vars. **lahillei** (p. 248), Sargasso Sea, **pseudomolgula** (p. 248) [locality not cited], **humile** (*Glossophorum h.* Lahille) (p. 249), **brementi*** (p. 249), France, and **luteum** (*P. l.* Giard) (p. 249); **POLYCLINELLA** (p. 254), type *P.* **azemai*** (p. 254), Mediterranean. Didemnidae: *Trididemnum* **brementi** (p. 271), *T.* **duci*** (p. 272) and *Didemnum* **grassei*** (p. 278), France; *D. dentatum**, recharacterized. Keys are presented to the genera and spp. of Ascidia from the coasts of France. Morphological studies are presented on the muscles of the digestive tube, and of the tunic of Polyclinidae, the sexual organs and tentacles of Didemnidae; dorsal raphe of Ascidiidae. Histophysiological observations are made on the tunicate cells of *Polysyncraton,* pleochromatic cells of *Diazona* and of *Phallusia,* the pigmented cells of *Lissoclinum bataillonl,* the blood of Cynthiadae, the purine cells and experimental inflammation. The composition and characters of the fauna of France, and its relation to neighboring populations, are discussed, and a few associations studied. The parasites of Ascidia are discussed, including data on the culture of the fungus *Nephromyces molgularum* on agar-purines; *Selenidium* (?) **giganteum** (p. 357), a gregarine from the stomach of *Polycarpa pomaria;* description of stages of *Selysina* **dubosqui*** (p. 359), a sporozoan (Selysinidae) parasite of *Styela partita* and *P. pomaria;* and *Pseudoklossia* **legeri*** (p. 365), a coccidian parasite of *Styela* and *Polycarpa;* ecological observations concerning certain metazoan parasites or commensals of Ascidia are also made, with a list of Copepoda living in Ascidia. This memoir is a revision of the known species of Ascidia, and of their described parasites. The author expounds his ideas relative to classification, and makes some suggestions relative to geographical distribution, to associations and to parasitism.—*From H. Harant's abstract (transl.).*

14950. **HARTMEYER, R., und W. MICHAELSEN.** Ascidiae Diktyobranchiae und Ptychobranchiae. Fauna Südwest-Australiens 5(6): 251-460. Map. 61 fig. Gustav Fischer: Jena, 1928.—This work was finished after the death of Dr. Hartmeyer, and each section is attributed to its actual author. In all, 57 spp. are treated in detail with bibliography and synonymy, distribution and description. Diktyobranchiae: Cionidae, *Ciona intestinalis** anatomical study. Perophoridae, 2 spp. Ascidiidae, 11 spp., including *Ascidia malaca* v. *australiensis** (redescribed), *A. rhabdophora**, *A. dubia gemmata**, *A. munda**, *A. austera**, *A. latesiphonica** (redescr.), *A. glabra* (redescr.), and *Phallusia obesa** are considered.

Rhodosomatidae, *Rhodosoma turcica** treated. Ptychobranchiae: Stelidae, general considerations are given of the family and of the subfam. Botryllinae, also of 7 spp. and vars., including *Botryllus anceps*, and *B. gracilis** (redescr.). In Polyzoinae 4 spp. are discussed including *Oculinaria australis**, and *Stolonica australis** redescr. In Styelinae 14 spp. are considered, including *Polycarpa aurata* f. *clavata**, *P. moebii**, *P. abjornseni** redescr., *P. hartmeyeri** redescr., *Cnemidocarpa polyphlebodes**, *C. posthuma**, *C. irma**, and *C. hartogi**, the last 3 also redescribed. Pyuridae, 18 spp. and vars. are considered, including *Microcosmus claudicans* spp. **squamiger** (*M. exasperatus* ssp. *australis* Michaelsen) (p. 405), *Pyura australis**, *P. ostreophila** redescr., *P. australiensis* f. **busseltonensis** (p. 429), S. Australia, Victoria, *P. stolonifera* ssp. *waia*, *P. albanyensis** and *P. momus* f. *galei* redescribed. Molgulidae, 3 spp. are discussed, including *Molgula nodosa** and *M. reducta** redescribed. The bibliography contains 98 references.

14951. MICHAELSEN, W. Ascidiae Krikobranchiae. *Die Fauna Südwest-Australiens* 5(7/9): 461-558. 12 fig. 1930.—Clavelinidae: Reorganization of the family with new diagnoses of many spp.; discussion of the origin and evolution of the cloaca and the consequent modification of the atrial aperture, i.e., a radial structure becoming transformed into a bilaterally symmetrical one with an atrial tongue ["*Atrialzunge*"], and its relations in the Synoicidae and Didemnidae. The earlier proposal to unite the families Clavelinidae and Polycitoridae is now modified and they are regarded as subfamilies. Subfam. Clavelininae emend.; *Podoclavella* Herdm. emend.; *P.* **ostrearium** (p. 467); *Oxycorynia* v. Dr. emend.; the temporary generic name *Nephtheis* Gould is rejected (the name in any case being only an erroneous variant of the alcyonarian genus name *Nephthea* Sav.); *Oxycorynia* (=*Colella* Herdm.); *O. fasciculatis* v. Dr. (=*Nephtheis* ? Gould, *Colella thomsoni* Herdm., *Nephtheis centripetens* Sluiter), with fuller description; *Clavelina* Sav. emend. (=*Chondrostachys* Macdonald *Stereoclavella* Herdm. part., ? *Pycnoclavella* Garstang, *Synclavella* Caullery); *C. enormis* Herdm., with fuller description; *C. cylindrica* Quoy & Gaim. (=*Chondrostachys macdonaldi* Bronn), with fuller description. Subfam. Polycitorinae emend.; doubtful genera, *Aphanibranchion* Oka and *Eucoelium* Sav.; *Sigillina* Sav. (emend.) is divided into 5 subgenera: *Archidistoma* Garstang emend., subgenotype *A. aggregatum* Garst.; *Eudistoma* Caullery emend., subgenotype *Distoma rubra* Sav.; *Paessleria* Mich. emend., subgenotype *P. magalhaensis* Mich.; **HYPERIODISTOMA** (p. 490) subgen., type *Colella möbiusi* Hartmr.; *Sigillina* Sav. emend., subgenotype *S. australis* Sav. *Sigillina* (*Paessleria*) *magalhaensis** Mich., fuller description; *Polycitor* **circes*** (p. 495); *Cystodytes dellechiajei* f. *durus* v. Dr., synonyms listed, *C. draschei* Herdm. is united with *C. dellechiajei;* 3 forms of *C. dellechiajei* are temporarily retained: f. *durus* v. Dr., f. *typicus*, and f. *ceylonensis* Herdm.; *Distaplia stylifera* (Kowalewsky) (=*Polyclinum micropnous* Sluiter, *Holozoa bursata* Van Name); discussion of the synonymy and relationships; *D. cerebriformis* Quoy & Gaim and *Sycozoa sigillinoides* Lesson brief annotations on geographical distribution. Didemnidae: *Tridemnum lüderitzi* Mich., fuller description; *Leptoclinides dubius* f. **kingi** (p. 507); *L.* **glauerti*** (p. 511); discussion on the form of the colony with reference to the migration of the cloaca through the thickness of the colony till in *L.* **glauerti*** (p. 511) the arrangement of a *Pyrosoma* colony is attained; *Didemnum* **roberti*** (p. 516); *D.* (?) **turritum*** (p. 521) possibly the type of a new genus; *Diplosomoides* **ostrearium** (p. 526); *Diplosoma spongiforme* (Giard) var. (?), discussion of the morphological characters of the sp. Synoicidae: *Macroclinum* **papilliferum*** (p. 530); *M. hypurgon* f. **galei** (p. 535); *Polyclinum* Sav., discussion of the cloacal system and of the atrial tongues (p. 539); *P. neptunium* f. **typicum*** and f. **incrustatum** (p. 542); *P. macrophyllum* ssp. **phortax*** (p. 546). Distribution. Deals with the krikobranchiate ascidians of the marine littoral and shallow water regions off S. W. Australia from Shark's Bay to King George's Sound, giving a table of all known spp. from this region together with their usual occurrence and their wider distribution in relation to the wider distribution of related forms.—*W. Michaelsen (transl. by M. L. Hett).*

14952. OKA, ASAJIRO. On a new genus of simple ascidians intermediate between "Molgula" and "Rhizomolgula" ("Hemirhizomolgula" nov. gen.). *Proc. Imp. Acad.* [*Tokyo*] 2(4): 174-176. 1926.—**HEMIRHIZOMOLGULA** (p. 174), type *H.* **utidai** (p. 174), N. Sakhalin, type in author's coll.; *Rhizomolgula* **japonica** (p. 176), Japan.

14953. OKA, ASAJIRO. On the mode of gemmation in Dictyostyela depressa n. g. n. sp. (Ascidiae sociales). *Proc. Imp. Acad.* [*Tokyo*] 2(7): 348-351. 2 fig. 1926.—**DICTYOSTYELA** (p. 348), resembling *Synstyela* and *Goodsiria*, type *D.* **depressa*** (p. 348), on *Haliotis gigantea*. The buds are not formed from the creeping stolon, but directly from the lateral region of the parent ascidiozooid. This peculiar type of budding may be termed "pseudo-stolonial" and seems to throw light upon the nature of colony formation in certain genera of ascidians in which the existence of asexual reproduction has hitherto remained doubtful. It appears highly probable that *Stolonica* also reproduces by means of this peculiar mode of gemmation and afterwards loses by atrophy the stolon-like tubes which connected the different ascidiozooids of the colony.

14954. OKA, ASAJIRO. A striking case of mimetism in simple ascidians. *Proc. Imp. Acad.* [*Tokyo*] 2(8): 423-425. 1926.—*Ascidia* **dolosa** (p. 424) and *Cynthia* **snaboja** (p. 424) both mimic *Molgula hartmeyeri* Oka which grows in the same locality.

14955. OKA, ASAJIRO. A revision of the spiniferous species of "Cynthia" (Ascidiae simplices), with description of a new species. *Proc. Imp. Acad.* [*Tokyo*] 2(10): 559-561. 1926.—*C.* **pachyderma** (p. 559), from Misaki. The author made a comparative study of all the spiniferous spp. of *Cynthia* (except *spinifera* and *okai*) and concludes that they do not constitute a natural group but must be regarded as being polyphyletic in origin. A table shows the differences in the most important anatomical characters. Suggestions for further changes are made.

CYCLOSTOMATA, ELASMOBRANCHII, AND PISCES

14956. [AMBROZ, A. I.] АМБРОЗ, А. И. Сельдь (**Clupea harengus pallasi C. V.**) залива Петра Великого. Биологический очерк. **(The herring of Peter the Great Bay. A biological sketch.)** [English summary.] Известия Тихоокеанского Научного Института Рыбного Хозяйства (*Bull. Pacific Sci. Fisheries Inst.*) 6: i-viii+1-313. 7 maps, 30 graphs. 1931.—This sp. ranges from Korea to Bering Strait and perhaps to the estuary of the Kolyma River. Within these limits it is distributed universally but not in equal quantities. The herrings of different shoals differ greatly in length and weight. Fatness varies according to season and sex. From June

to October only the 2-year-old fish remain near the shores. In the late fall the 3-year-old fish approach the shores and are followed by the 4-year-olds. The length of life in Peter the Great Bay is 13 years. Cessation of feeding takes place only just before and during spawning. The food of adults is mostly Crustacea (Copepoda, Mysidae, Amphipoda); more rarely the worm *Sagitta* and the eggs of fish. During the first 5 or 6 months of their life herrings reach an average length of 110 mm. During the winter the rate of growth slows down considerably, especially after the 2nd winter. The rate of growth is far more rapid here than in the White Sea. Sexual maturity is attained by some of the 2-year-old fish and by all of the 3-year-olds. Sexually productivity lasts as long as life. The number of eggs of an individual varies from 10,836 to 134,100, depending upon age, weight, and length of the fish; the average number in the general herring migration of 1927 was 72,178. Spawning extends from March to May, according to the latitude, being later in the north. The eggs are demersal. Spawning takes place in water varying in depth from 15 cm. to 10 m. or more, at water temp. a little below or near 0°. An individual deposits all its eggs at the same time. The incubation period varies from 15 to 50 days, according to the temp.; the sum of the temp. of the embryonal period in 4 cases varied from 136° to 143.1°. Shoreward migration of the older fish is determined by maturation of the sexual products. There are 4 successive migrations, first of the older fish (8 to 4 years), then of the 4-year-olds, 3-year-olds, and 2-year-olds; each of these age groups contains a certain percentage of other groups. The migrations extend from March to late May or even June. The spring migrations in the bays take definite courses, varying with the age group. Within a few days after hatching the fry leave the spawning grounds for deeper water. The herring shoal of Peter the Great Bay is purely local, and the region is regarded as a closed basin for herring. The 3-year age group was most numerous (32.3%) in the general catch of 1927, each succeeding age group appearing in lesser amount. Bibliography of 73 titles.

14957. **ANCONA, UMBERTO D'. Murenoidi (Apodes) del Mar Rosso e del Golfo di Aden. Materiali raccolti dal Prof. Luigi Sanzo nella Campagna della R. N. "Ammiraglio Magnaghi" 1923-24. [Muraenoids (Apodes) from the Red Sea and Gulf of Aden, collected by Prof. Luigi Sanzo on the cruise of the R. N. "Ammiraglio Magnaghi" 1923-24.]** *R. Comitato Talassografico Italiano Mem.* 146: 1-146. Map. 5 pl. 1928.—This collection includes 5 specimens definitely young or adult; 93 between larval and semilarval, and 24 prelarval stages hatched on the boat. The definitely adult or young belong to the species: *Ophisoma anago* (Schlegel) new for the Red Sea, *Muraena hepatica* Rüpp., *M. undulata* (Lac.), *Muraena* sp. juv., *Ophichthys* sp. juv. (possibly *O. arenicola* Klz.). The vertebrae of all were counted by radiograph, thus establishing the diagnoses. Larvae and semilarvae are described in detail. They belong to the following larval species, mostly new. Where possible the referable adult species is given, otherwise the adult muraenoid family. All species are figured. Congridae: *Leptocephalus ophisomatis* **anagoi*** (p. 17); *L.* **sanzoi*** (p. 27); *L.* **macrenteron*** (p. 32); *L. mauritianus** Pappenheim described; *L. congri* **cinerei*** (p. 38); *L.* **congroides*** (p. 43); *L.* **magnaghii*** (p. 44); *L.* **cotroneii*** (p. 47). Family Incertae sedis: *L.* **arabicus*** (p. 51). Nettastomidae: *L.* **saurencheloides*** (p. 52); *L.* **lateromaculatus*** (p. 56); *L.* **bellottii*** (p. 60). Synaphobranchidae: *L.* **synaphobranchoides*** (p. 63). Ophichthyidae: *L.* **ophicthoides*** (p. 65). Echelidae: *L.* **echeloides*** (p. 69). Muraenidae: *L.* **grassianus*** (p. 70); *L. muraenae* **undulatae*** (*L. peterseni* Weber) (p. 75); *L.* **muraenoides*** (p. 79); *L. muraenae* **hepaticae*** (p. 82); *L.* **erythraeus** (p. 87). Almost all species described present similarities to some of those noted for the Mediterranean; none, however, is certainly common to that sea. There is, apparently, no exchange of Apodes across the Suez Canal. The geographic, seasonal, and bathymetric distribution of the species is also considered. The following are among interesting facts recorded: The absence of leptocephali in low-lying waters, in particular the Gulf of Suez; the greater abundance of leptocephali in the most southern part of the Red Sea; the abundance of leptocephali in the winter months in the Gulf of Aden and the contemporaneous immigration into the Red Sea across the Strait of Bab-el-Mandeb. A tentative systematic arrangement is made of larval species of Apodes hitherto described collectively. The author maintains that, putting into synonymy all those not corresponding to new species, about 96 spp. may be distinguished. These, he believes, fall into natural groups, among which may be found those corresponding to the families: Anguillidae, Congridae, Nettastomidae, Ophichthyidae, Echelidae, Nemichthyidae, and Muraenidae. He indicates the species of which the adult species was noted with the name corresponding to that of the latter, attributing it to the author who identified it. The following are also proposed: *Leptocephalus* **weberi** (*L. hjorti* Weber) (p. 104), *L.* **roulei** (p. 113), *L.* **tilurus** (*Tilurus hyalinus* Facc.) (p. 117), *L.* **tiluropsis** (*Tiluropsis* sp. Roule) (p. 118).—*U. D'Ancona* (*transl. by F. La Monte*).

14958. **BELLOC, GÉRARD. Étude monographique du Merlu Merlucius merluccius L. (1e et 2e parties.)** *Rev. Trav. Office Pêches Maritimes* 2(2): 153-199. 7 maps. 25 fig.; (3): 231-288. Map. 14 fig. 1929.—The taxonomic position, species, varieties, and affinities of the hake (*Merlucius*) are treated, and the genus is diagnosed and characterized. The geographic and bathymetric distribution is discussed. Detailed descriptions, accompanied by illustrations, are given of the morphology and anatomy of the common European hake, and a case of hermaphroditism, comparatively rare in this genus, is reported. Information is also given on the common and scientific names of the European species. The hake is a fish of temperate zones and middle depths. It is represented in the north Atlantic by *M. merluccius* (a European sp.) and *M. bilinearis* (an American sp.); in the south Atlantic by *M. capensis* (an African sp.); in the north Pacific by *M. productus* (an Amer. sp.); in the south Pacific by *M. gayi* (Australian sp.). The European hake (*M. merluccius*), of which the fishery has been carried on for a long time, is fished today by trawlers from Cape Blanc to the Hebrides. The principal French fishing centers are Boulogne, Lorient, Arcachon, and especially La Rochelle. The hake is endowed with remarkable fecundity; the ♀ deposits 2-7 million eggs. Part 2 deals with the development of eggs and fry, and with the growth etc. (ethnic and sexual variations, diseases and abnormalities, albinism and melanism) of the adult. A dichotomous key is given to postlarval stages of the Gadidae. The eggs are pelagic; they are transparent and have a homogeneous vitellus and an oil globule; their development up to eclosion lasts about 65 hrs. The larva is pelagic until it reaches a length of about 4 cm. The adult may attain a length of 1.3 m. ("1 m. 30") and a weight of 15 kgm. Growth is rapid, varying with the latitude, being most rapid in a lower latitude. The ♀ grows faster than the ♂. Three growth periods of unequal rate, corresponding to 3 phases of the sexual cycle, are exhibited. A dwarf race of hake occurs in the Mediterranean. The limits of geographic distribution are: From Trondhjem Fjord, Norway, in the north, to Cape Blanc in the south. The hake is fished at a depth of 800 m. A bibliography is included.—*G. Belloc* (*transl. by F. La Monte*).

14959. **BORODIN, N. A. On the genus Anostomus (family Characinidae).** *Bull. Mus. Comp. Zool. Harvard Coll.* 72(2): 37-52. 4 pl. 1931.—The nomenclatural history and taxonomic relationships of this genus are reviewed. The subfam. Anostominae is considered to be composed of *Anostomus, Leporinus, Leporellus, Curimatus, Prochilodus, Rhytiodus, Anodus,* and *Chaenotropus.* A key is given to the 4 subgenera recognized: *Anostomus, Schizodon, Schizodontopsis,* and *Lahilliella.* The spp. represented in the collections of the Mus. Comp.

Zool. are redescribed and synonymies are given. *Anostomus* garmani* (p. 47) and *A.* rostratus* (p. 50), Brazil; types in Mus. Comp. Zool.

14960. **BURKENROAD, MARTIN D. Notes on the sound-producing marine fishes of Louisiana.** *Copeia* 1931 (1): 20-28. 1931.—Capture by man of sound-producing fishes is probably a stimulus to sound production similar in effect to some stimulus provided by the normal environment, to which the response of the fish is adaptive. Sound production in many fishes probably has a defensive function. Sound production in *Hyporamphus unifasciatus* and *Chaetodipterus faber* is described, also in a number of fishes closely related to other, previously described, sound-producers. Sound produced by the movement of the pectoral spine of *Galeichthys milberti* is not merely incidental to the defensive fixation of the spine. Methods of sound-production not previously described for these forms are noted in *Monacanthus hispidus* and certain sciaenids. The importance of the teeth as sound-producing organs of fishes is emphasized. The drumming muscles of one sciaenid, *Pogonias*, are intrinsic to the swim-bladder. Twenty-five sound-producing fishes of Louisiana are classified. The list suggests that sound production has arisen independently in the different groups.—*From author's summary.*

14961. **CRAIG-BENNETT, A. The reproductive cycle of the three-spined stickleback, Gasterosteus aculeatus, Linn.** *Phil. Trans. Roy. Soc. London B* 219(466): 197-279. 4 pl., 3 fig. 1931.—The reproductive cycle of *G. aculeatus* in its natural habitat shows a close relation to the temp. of the habitat. In the ♂ the annual beginning of spermatogenesis occurs in Aug., and experimentally this was shown to be conditioned by the high temp. of the habitat. The time during which spermatogenesis is in progress varies inversely with the rate of fall of temp. of the habitat in autumn. The natural breeding season begins when the rate of vernal rise of temp. reaches the order of 1°C. per week, this usually occurring in the latitude in which the samples were taken in April or May. In many cases the ♂ will have completed spermatogenesis prior to the breeding season and is potentially mature for a period which may amount to 2 months. During this period the secondary sexual characters and the breeding instincts are absent but the testes of such fish will fertilize eggs artificially. The development of the secondary sexual characters of the ♂ is dependent on the joint action of 2 factors: (1) The presence of well developed interstitial tissue in the testes; (2) on the fish being subjected to a rise of temp. of the order of 1°C. per week. In the natural habitat the development of interstitial tissue precedes a rise of temp. and when such fish are subjected to the rise of temp. a rapid development of the secondary sexual characters results. Under experimental conditions this order may be reversed and then a gradual development of the secondary sexual characters accompanies the development of the interstitial tissue. The rate of degeneration of the interstitial tissue varies directly with the temp., and it is impossible to produce a continuous breeding season. By suitable experimental conditions the breeding season, which in the natural habitat is restricted from April to July, may be developed at any time of the year. The cycle of the germ cells is conditioned by the temp. cycle, but that of the interstitial tissue is not directly dependent on either the physical environment or the food of the fish. A rapid development of the interstitial tissue results from either substerility doses (1 Unit Skin Dose) of hard x-rays, or from the injection of an alkaline extract of mammalian anterior lobe of pituitary.—*A. Craig-Bennett.*

Lab.*) 2(2): 69-79. 3 fig. 1929.—The following 6 spp. are recorded from this river, which flows from the Elburz Mts. southward into a salt lake, Daria-i-Namak: *Salmo fario fario; Leuciscus cephalus orientalis; Varicorhinus* bergi* (p. 72); *V.* nikolskii* (p. 74); *Barbus* kessleri* (p. 75); and *Alburnoides bipunctatus fasciatus.* There are descriptive notes on the previously known forms and remarks on faunal relationships.

14965. **EIGENMANN, CARL H., and GEORGE S. MYERS. The American Characidae.** *Mem. Mus. Comp. Zool. Harvard Coll.* 43(5): 429-558. 11 pl. 1929.—Part 5, concluding the monograph, edited by Myers after Eigenmann's death, and with supplement by Myers. About ⅓ of the species are treated in the whole monograph. Genera reviewed in this part are *Piabina, Creatochanes, Phenacogaster* and related genera, of the Tetragonopterinae; also the genera of subfamilies Rhoadsiinae, Glandulocaudinae, Iguanodectinae and Stethaprioninae. *Gephyrocharax* major Myers (p. 479), Bolivia; *Ephippicharax* franciscoensis* (p. 506), San Francisco Basin. The S. Amer. Tertiary characins are reviewed, including: **LIGNOBRYCON** (p. 513), type *L.* ligniticus (*Tetragonopterus l.* Woodward) (p. 513), Brazil; and *Eobrycon* branneri* Eigenmann (p. 514), Tertiary lignite, São Paulo, Brazil, type in Indiana Univ. The supplement by Myers includes accounts of expeditions, additional information on various species and descriptions of: *Moenkhausia* simulata* Eigenm. & Pearson (p. 523), *M.* crisnejas* Pearson (p. 524), *Knodus* megalops Myers (p. 527) and *Hemigrammus* paipayensis Pearson (p. 533), Peru; *Hyphessobrycon* coelestinus Myers (p. 535), Goyaz, Brazil; **BRYCONACIDNUS** Myers (p. 545), type *B.* ellisi (*Hyphessobrycon e.* Pearson (p. 545)); *B.* hemigrammus (*Bryconamericus h.* Pearson) (p. 546). Plates include one of x-rays. Sexual dimorphism of Glandulocaudinae is expressed by different organs in different species.—*C. L. Hubbs.*

14966. **GINSBERG, ISAAC. On the difference in the habitat and the size of Cynoscion arenarius and C. nothus.** *Copeia* 1931(3): 144. 1931.—*C. arenarius* averages slightly larger in size, and is more of a shallow-water form, while *C. nothus* occurs more in deeper water. The 2 occur together, however, at intermediate depths in the Gulf of Mexico.

14967. **GUDGER, E. W. The fourth Florida whale shark, Rhineodon typus, and the American Museum model based on it.** *Bull. Amer. Mus. Nat. Hist.* 61(9): 613-637. 9 pl. 4 fig. 1931.—This 32-ft. specimen was captured June 9, 1923, near Marathon, Florida. Measurements and photographs (moving and stills) were made of the living or just dead fish. From these, helped by all other known figures, the model was made. The characteristic features of the fish are described, its habits considered, and its occurrence in the Atlantic and its dependencies discussed. Photographs of the model and figures of all known mounted specimens (so far as available) are reproduced for comparative study.—*E. W. Gudger.*

14968. **GUDGER, E. W., and W. H. HOFFMANN. A shark encircled with a rubber automobile tire.** *Sci. Monthly* 33(192): 275-277. 1 fig. 1931.—A ♂ shark of non-determinable species was captured off Havana harbor, with an automobile tire encircling its body behind the pectoral fins and in front of the dorsal. At Havana, garbage, street cleanings, and other debris are loaded on scows, and then are towed out to sea and dumped. Sharks collect around these to feed. It is presumed that this shark thrust its head through the tire, laid its pectorals

flat against its sides and pushed through until the dorsal fin was caught against the tire, then on expanding its pectorals, it was caught in the tire.—*E. W. Gudger.*

14969. **HERRE, ALBERT W.** A check list of fishes from the Solomon Islands. *Jour. Pan-Pacific Res. Inst.* [*Honolulu*] 6(4) : 4-9. 1931.—A brief notice of previous work is given, together with a list of 344 spp.

14981. **[SOLDATOV, V. K., and G. J. LINDBERG.]** СОЛДАТОВ, В. К., и Г. У. ЛИНДБЕРГ. Обзор рыб дальневосточных морей. (A review of the fishes of the seas of the Far East.) [English summary.] Известия Тихоокеанского Научного Института Рыбного Хозяйства (*Bull. Pacific Sci. Fisheries Inst.*) 5: i-xlvii + 1-576. 16 pl., 76 fig. 1930.—In this work, based upon collections made by various ichthyologists during the past 20 years, the authors aim to furnish a handbook for the ready identification of fishes occurring in Russian Pacific waters. Previous work on the fishes of the region is briefly reviewed. The present work covers the region from Korea to Bering Strait. It deals chiefly with marine fishes, but includes some fresh-water spp. from the river mouths. Fishes recorded in the literature from adjacent regions are also treated. The spp. so far found in the region number 347, to which 113 spp. are added as probably occurring. The systematic account of spp. includes references to the literature, brief descriptions, and distributional records. Keys to families, genera, and some spp. are given. New forms are from the Pacific Coast of Siberia, unless otherwise stated; their descriptions are given in both English and Russian. Trygonidae: **UROLOPHOIDES** Lindberg (p. 24), allied to *Urolophus,* type *Urolophoides* **giganteus*** (p. 26). Syngnathidae: *Syngnathus schlegeli* **soldatovi*** Lindberg (p. 79), Siberia and Korea. Cottidae: **RADULINOPSIS** Soldatov & Lindberg (p. 183), near *Stelgistrum,* erected for *R.* **derjavini*** Soldatov & Lindberg (p. 185) and *R.* **derjugini*** Soldatov (p. 189) ; *Eurymen* **bassargini*** Lindberg (p. 286). Cyclopteridae: *Cyclopteropsis* **lindbergi*** Soldatov (p. 318) ; *C.* **popovi*** Soldatov (p. 322). Liparidae: *Neoliparis* **mednius*** Soldatov (p. 339) ; *Liparis* **niger*** Soldatov & Lindberg (p. 352) ; *L.* **dulkeiti*** Soldatov (p. 356) ; *L.* **tartaricus*** Soldatov (p. 361) ; *L.* **brashnikovi*** Soldatov (p. 364) ; *L.* **dubius*** Soldatov (p. 366). Bathymasteridae: *Bathymaster* **derjugini*** Lindberg (p. 478). Cryptacanthodidae: **CRYPTACANTHOIDES** Lindberg (p. 482), near *Delolepis,* type *C.* **bergi*** Lindberg (p. 484). The types of some new spp. are in the Pacific Res. Sta. of Fisheries at Vladivostok or in the collections of the Far East Expedition; the depository of the other types is not stated. Fourteen families, 32 genera, and 45 spp. are recorded as new to the region. There is a full index.

14982. **SPARTÀ, A.** Contributo alla conoscenza di uova e larve nei Labridi. II. Uova e larve di Crenilabrus ocellatus Forsk. [Egg and larva of C. ocellatus.] *R. Comitato Talassografico Italiano, Mem.* 182. 6p. 1 col. pl. 1931.—The embryonic* and early larval* stages are described.

14983. **VAN DER HORST, C. J.** Some South African siluroid fishes. *Ann. Transvaal Mus.* 14(3) : 246-250. 4 fig. 1931.—*Synodontus zambezensis,* new to Limpopo River system (Transvaal and Portuguese East Africa). Specimens of *Amphilius* from Transvaal and Natal are described and referred to *A. grandis* Blgr., hitherto unknown from South Africa; however, an accompanying figure, evidently referring to the specimens discussed, is labeled "*A.* **transvaaliensis** n. sp." (p. 247). Three new spp. of *Chiloglanis,* a genus hitherto unknown in S. Africa, are described from Transvaal: *C.* **pretoriae*** (p. 248) ; *C.* **swierstrai*** (p. 249) ; *C.* **pumilus*** (p. 250).

14984. **VLADYKOV, VADIM.** Sur un nouveau genre de Cobitides: Sabanejewia. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(1) : 85-90. 1929.—**SABANEJEWIA** (p. 86), near *Cobitis,* type *S.* **balcanica** (*Cobitis b.* Karaman = *C. montana* Vladykov) (p. 87), of which an emended description is given; *S.* **aurata** (*Acanthopsis a.* Filippi) (p. 88). The genus probably includes also *Cobitis taenia hohenackeri* Kessler and *C. t. aralensis* Kessler.

14985. **WEBER, MAX, and L. F. de BEAUFORT.** The fishes of the Indo-Australian Archipelago. Vol. 5. Anacanthini, Allotriognathi, Heterosomata, Berycomorphi, Percomorphi: Families: Kuhliidae, Apogonidae, Plesiopidae, Pseudoplesiopidae, Priacanthidae, Centropomidae. 458p. 98 fig. E. J. Brill, Ltd.: Leiden, 1929.—The fifth volume of this well known work, which is very useful and labor-saving to students of East Indian fishes and those from adjacent regions, follows the

ıeral plan of the preceding volumes. Keys to the nilies, genera and species are given, followed by deiptions. The scope of the paper is readily gathered ım the title. As a result of an examination of Bleeker's ginal types in the Leyden Mus., a number of his names ɔ reduced to synonymy. Aside from these new synyms listed below, many have undoubtedly been left t of this abstract as not being definitely stated or imed to be new by the authors. The large group of species ɛated under *Apogon* are divided into smaller genera ı the basis of number of dorsal spines and number of ys in the anal fin. The larval stages of 2 species of eterosomata are described and figured without being ımed. *Coryphaenoides* **sibogae** (p. 29), Flores Sea, 694 .; *Pseudorhombus* **quinquocellatus** (p. 104), Strait ladura, near Kangeang Ids., 80-100 m.; *Nematops* **:andisquama*** (p. 134), St. Nikolaas Bay, 108-162 m.; *ımariscus* **sunieri** (p. 141), Nikolaas Bay, 108-252 m.; *chirus* **abnormis** (p. 163), market of Makassar, Celebes; *pogon* **gjellerupi** (p. 285), *A.* **heurni** (p. 286), *A.* **damıermani** (p. 338) and *Ambassis confinis* **occidentalis** (p. 20), New Guinea. *Symphurus* **regani*** (*Aphoristia longata* Weber 1913, preocc. by *Symphurus elongatus* Gunther)) (p. 210); *Bothus intermedius* (Bleeker) (=*Anticitharus annulatus* Weber); *Solea lascaris* Risso (=*S. margaritifera* Gthr.); *Liachirus melanospilos* (Bleek.) (=*L. nitidus* Gthr.); *Cynoglossus puncticeps* (Richardson) (=*Plagusia brachyrhynchus* Bleek.); *Holocentrum cornutum* Bleek. (=*H. melanospilus* Bleek.); *Myripristis pralinius* C. & V. KARL PATTERSON SCHMIDT, *Editor,* Reptilia

(See also in this issue Entries 12135, 12458, 12459, 12472, 12488, 12630, 13076, 13097, 13269, 13513, 13551, 14240, 14303 14406, 14416, 14433, 14571)

GENERAL

14986. ANGEL, F. Reptiles et batraciens recueillis en Indo-Chine par la Mission de MM. Delacour et Lowe. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(6): 445-447. 1928.—A list of 16 reptiles and 6 amphibians, with locality records and with descriptive notes on some spp.

14987. ANGEL, F. Liste des reptiles et batraciens du Haut-Laos recueillis par M. Delacour. Description d'un genre, de deux espèces et d'une variété d'ophidiens. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(1): 75-81. 4 fig. 1929.—A list of 31 spp. of reptiles and 1 sp. of caecilian from Xieng-Khouang, French Indo-China, with descriptive notes on some of them. Colubridae: **PARATAPINOPHIS** (p. 76), near *Tapinophis,* erected for *P.* praemaxillaris* (p. 78); *Plagiopholis* **delacouri** (p. 78); *Ablabes multicinctus* **bicolor** (p. 79). Types in Paris Mus.

14988. GANDER, FRANK F. Observations on an alligator lizard. *Copeia* 1931(1): 14-15. 1931.—A captive *Gerrhonotus scincicauda webbii* fed on various insects and on the young of *Sceloporus occidentalis biseriatus* and *Mus m. musculus.* A *Hyla regilla* gained protection from the *Gerrhonotus* by raising itself on its toes, puffing itself up, and possibly emitting some protective vapor.

14989. SCHOUTEN, GUILLERMO B. Contribuciones al conocimiento de la fauna herpetológica del Paraguay y de los paises limítrofes. [Herpetology of Paraguay and neighboring countries.] *Rev. Soc. Cient. Paraguay* 3(1): 5-32. 2 fig. 1931.—From personal observations and from the literature, the author gives an account of the food habits and reproduction of Paraguayan snakes. A systematic list of spp., a discussion of the venomous forms, and notes on economic importance are added.

14990. SMEDLEY, N. On some reptiles and a frog from the Natuna Islands. *Bull. Raffles Mus.* 5. [46]-[48]. 1931.—These islands are notable for a predominance of Bornean elements in their fauna. An annotated list is given of 9 reptiles and 1 amphibian collected by F. N. Chasen in 1928. The following are new to the Natunas: *Draco cornutus* (emended description), *D. formosus, Boiga drapiezii,* and *Rana glandulosa.*

14991. VINCIGUERRA, D. Risultati zoologici della Missione inviata dalla R. Società Geografica Italiana per l'esplorazione dell' oasi di Giarabub (1926-1927). Rettili, batraci e pesci. [Zoological results of the Mission sent by the Ital. R. Geogr. Soc. for exploring the Oasis of Jarabub (1926-1927). Reptiles, batrachians, and fish.] *Ann. Mus. Civ. Storia Nat. Genova* 52: 324-345. 1925/1928.—A record of 20 spp. of Reptilia, 1 Batrachia, 1 Pisces, with comments on each.

REPTILIA

14992. ABEL, OTHENIO. Eine Reptilienfährte aus dem Oberen Perm (Grödener Sandstein) der Gegend von Bozen in Südtirol. *Palaeobiologica* [*Vienna*] 2(1/3): 1-14. 1 pl., 2 fig. 1929.—Stratigraphy and flora suggest an Up. Permian age for this sandstone. The track is referred to *Herpetichnium acrodactylum** Pabst, type, from the Rotliegende, consists of the left hind foot of a 5 toed vertebrate with sharp claws and probable phalangeal formula of 2, 3, 3, 3, 3, hence presumably made by a theriodont, mammal, or turtle, more probably the last.—*A. S. Romer.*

14993. BERTONI, A. de W. Nuevo ofidio tiplópido del Paraguay. *Rev. Soc. Cient. Paraguay* 3(1): 4. 1931.—*Helminthophis wilderi* recorded as new to Paraguay.

14994. BRONGERSMA, L. D. Notes on the list of reptiles of Java. *Treubia* 12(3/4): 299-303. 1930.—Critical notes on 30 spp.

14995. CARPENTIER, C. J. Note sur un serpent nouveau pour le Maroc. *Bull. Soc. Sci. Nat. Maroc* 10 (1/6): 19-20. 2 fig. 1930.—*Tropidonotus natrix**.

14996. [CHEKANOVSKAÏA, O.] ЧЕКАНОВСКАЯ, О. К морфологии черепа змей Typhlopidae, Glauconidae и Ilysiidae. [Morphology of the skull of Typhlopidae, Glauconidae and Ilysiidae.] [German summary.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 55-68. 10 fig. 1930.—A comparative study of the skulls of Typhlopidae, Glauconidae, and Ilysiidae leads to the conclusion that Glauconidae and Typhlopidae have very many traits in common even though they have become extremely specialized, showing indication of many traits of adaptation to subterranean life. All 3 families have a very compact arrangement of skull bones. The skulls of snakes of the family Ilysiidae

exhibit primitive traits in having a process basipterigoidei and in the presence of teeth on the praemaxillary.—*S. A. Corson.*

14997. **DERANIYAGALA, P. E. P. The Testudinata of Ceylon.** *Ceylon Jour. Sci. Sect. B. Zool. and Geol. Spolia Zeylanica* 16(1): 43-88. 7 pl. 1930.—Detailed descriptions of 7 species (*Dermochelys coriacea*, Emyda granosa ceylonensis*, Testudo elegans, Geoemyda trijuga thermalis, Chelonia mydas, Eretmochelys imbricata,* and *Caretta caretta**), belonging to as many genera, are given; the descriptions are accompanied by observations on food, reproduction, oviposition, variation, and distribution. A bibliography of 26 titles is appended.—*S. C. Bishop.*

14998. **DERANIYAGALA, P. E. P. The crocodiles of Ceylon.** *Ceylon Jour. Sci. Sect. B. Zool. and Geol. Spolia Zeylanica* 16(1): 89-95. 2 pl. 1930.—Diagnostic characters, habits, and distribution of the 2 species of crocodile found in Ceylon; the gregarious tank form *Crocodylus palustris**, and the solitary estuarine form *C. porosus**.—*W. G. Lynn.*

14999. **FORREST, H. E. Hawksbill turtle on Welsh coast.** *North Western Naturalist* 6(1): 26-27. 1931.—On *Chelonia imbricator,* new to the fauna of North Wales.

15000. **GUTHRIE, J. E. Snake notes.** *Proc. Iowa Acad. Sci.* 36: 349-359. 5 fig. 1929.—The massasauga, or prairie rattler, *Sistrurus catenatus* (Raf.) is probably becoming rare in Iowa, but the timber rattlesnake, *Crotalus horridus* L., still maintains itself in considerable numbers in those parts of the state favorable to it. The true prairie rattler, *Crotalus confluentus* Say, is found near the S. Dakota line in Plymouth County. Two specimens of *Virginia elegans* Kennicott are described from Keosauqua. Notes on the development of the fox-snake, *Elaphe vulpina* (Baird & Girard) and figures of some 2-headed snakes are given.—*F. A. Stromsten.*

15001. **HAUGHTON, S. H. Pareiasaurian studies. Part 2. Notes on some pareiasaurian brain-cases.** *Ann. South African Mus.* 28(1): 88-96. 6 fig. 1929.—Brain-cases of *Pareiasuchus* sp.* indet., *Anthodon serrarius*, Embrithosaurus schwarzi, Bradysaurus baini*,* and *Dolichopareia angusta** are described. [See also B. A. 4(10): entries 26206 and 26207.]—*A. S. Romer.*

15002. **HUENE, FRIEDRICH von. Über Rhynchosaurier und andere Reptilien aus den Gondwana-Ablagerungen Südamerikas.** *Geol. u. Palaeont. Abhandl.* [*Jena*] 17(1): 1-62. 8 pl., 14 fig. 1929.—Based on new material from Santa Maria, southern Brazil. A specimen consisting of a skull and vertebrae of *Scaphonyx australis* is described in detail, with a restoration of the palate. Isolated bones of S. American rhynchosaurs in Tübingen and the British Mus. apparently pertaining to *Scaphonyx, Cephalonia, Cephalastron* and *Cephalastronius,* are described and figured. Lydekker's description of *Hyperodapedon huxleyi** is discussed. A résumé is given of the British rhynchosaurs, based on a restudy of the material; *Hyperodapedon gordoni** and *Rhynchosaurus articeps** are redescribed. *Eifelosaurus triadicus* is probably a rhynchosaur. A definition of the rhynchosaurs is given, including 32 characters. Other Triassic rhynchocephalians are listed, and *Polysphenodon müller** is redescribed; it is near *Brachyrhinodon.* Certain Triassic footprints are probably rhynchocephalian. The Triassic rhynchocephalians are listed and arranged in 3 families: Sphenodontidae (*Brachyrhinodon, Polysphenodon*); Gnathodontidae (*Howesia Mesosuchus, ?Browniella, ?Paliguana*); and Rhynchosauridae (12 remaining forms). A number of Permian forms, including *Galephyrus, ?Broomia, Heleosaurus, Heleophilus, Youngina, Palaeagama, Noteosuchus, Saurosternum* and *?Heleosuchus* of S. Africa and the aquatic *Hovasaurus* and *Tangasaurus* are considered to be rhynchocephalians. The primitive rhynchocephalians are compared with other reptiles: Pelycosaurs, dinocephalians, thecodonts. They are genetically related to the last, but more primitive; the Eosuchia are probably ancestral to both thecodonts and rhynchocephalians. A true cynodont is represented by part of a skull previously described as *Gomphodontosuchus brasiliensis,* resembling both *Cynognathus* and *Diademodon;* this suggests that the S. Amer. beds are equivalent to the *Cynognathus* Zone of S. Africa. A jaw seems to show the presence of a parasuchian. There are further unidentified reptilian remains. The presence of rhynchosaurs and parasuchians in S. Amer. and their absence in S. Africa suggests a Triassic land connection between India and S. Amer. The geological evidence of this connection, via Australia and Antarctica, is discussed.—*A. S. Romer.*

15003. **KLAUBER, LAURENCE M. Notes on the worm snakes of the Southwest, with descriptions of two new subspecies.** *Trans. San Diego Soc. Nat. Hist.* 6(23): 333-352. Map. 1931.—*Leptotyphlops humilis* **slevini** (p. 338), Lower California, type in Calif. Acad. Sci.; *L. h.* **cahuilae** (p. 339), California (type, in author's coll.) and Arizona. Detailed notes are given on the differential characters of these forms and *L. h. humilis,* and on areas of intergradation, habits, and distribution.

15004. **KOPSTEIN, F. Herpetologische Notizen. III. Reptilien des östlichen Preanger (West-Java).** *Treubia* 12(3/4): 273-276. 1930.—A list of 43 spp. of snakes and 24 of lizards, with records of locality and altitude.

15005. **KOPSTEIN, FELIX. Die Giftschlangen Javas und ihre Bedeutung für den Menschen.** *Zeitschr. Wiss. Biol. Abt. A. Morph. u. Ökol. Tiere* 19(2/3): 339-363. 1930.—Five years work in Java on the problem of snake poisoning shows that injuries due to bites of poisonous snakes are infrequent and deaths rare. Full statistics concerning the frequency of fatal snake bites are lacking in Java, but in the year 1920 there occurred in the largest hospital of Java only 2 cases, and in the government hospital of Surabaja only 5. No one died in these hospitals of snake bites. The Annual Report for 1921 reports 5 cases, but no deaths. For the year 1923, the figures are as follows: Batavia, 3, Semarang, 13, and Surabaja, 5, with no deaths. The report of 1924 states that 132 patients with snake bites were treated in 171 hospitals of the Netherlands Indies and only 2 died. In spite of many years of experience the author knew personally of only 1 fatality due to snake bite. Even non-fatal cases were few in number. This question is interesting because in the adjoining Brit. India, according to Hugh W. Acton, during recent years there were approximately 25,000 fatalities from snake bite annually. Java has about 40,000,000 inhabitants and Brit. India approximately ten times as many. Java has 10 species of poisonous snakes, *Bungarus fasciatus, candidus,* and *flaviceps; Naja tripudians sputatrix* and *bungarus; Doliophis intestinalis* and *bivirgatus; Ancistrodon rhodostoma; Lachesis gramineus* and *puniceus,* while Brit. India has thirty. Since among the 10 types of snakes there are several fatally poisonous ones, occurring in numbers in various regions, we may ascribe the small number of cases of snake bite to the fact that these snakes are nocturnal and that they avoid human beings. The Javanese proteroglyph snakes are more dangerous for human beings than the viperids. The bite of the latter appears to be in general not deadly, for there are very few fatal cases reported in scientific literature. The observed cases of poisoning by *Lachesis* and *Ancistrodon* resulted in recovery. Cases of bite by *Lachesis gramineus* and *puniceus, Naja tripudians sputatrix* and *N. bungarus* were observed by the author. Animal experiments were carried on with the other types of snakes. The bite and poison of the sea snakes, Hydrophiinae, are discussed. The nomenclature is that of the monograph of De Rooij, "The reptiles of the Indo-Australian Archipelago."—*F. Kopstein (transl. by B. Kramer).*

15006. **MEGGITT, F. J. Insectivorous snakes.** *Nature* [*London*] 128(3227): 413. 1931.—Stomach and intestinal contents of 15 *Simotes violaceus* in Burma consisted almost wholly of insect remains.

15007. **MEHL, M. G. A new genus of mosasaurs from Mexico, and notes on the pelvic girdle of Platecarpus.** *Jour. Scientific Lab. Denison Univ.* 24(10/13): 383-400. 4 pl., 5 fig. 1929.—**AMPHEKEPUBIS,** erected to include *A.* **johnsoni*** (p. 383). The type, consisting of much

the pelvic girdle, hind limbs, and tail, is from a ality near Monterey, Mexico; horizon unknown, prenably Up. Cretaceous, type in Univ. of Missouri. neric characters include the recurved, slender unposed pubes with remarkably developed anterior ocess; the stout, non-spatulate ischia, and the comatively slender femora. Relationships perhaps closest h *Clidastes*. A pelvic girdle assigned to *Platecarpus olosaurus*) *abruptus* is described.—*A. S. Romer.*

15008. **MERTENS, ROBERT, und LORENZ MÜLLER.** r Nomenklatur einiger Eidechsen und Schlangen tropas. *Zool. Anz.* 84(11/12): 295-302. 1929.—Despite e criticisms of W. A. Lindholm, the authors main- n the validity of the following names: *Alsophylax crotis* (Blanford); *Agama aralensis* Licht.; *Ophisaurus odus* (Pallas); *Ablepharus kitaibelii* Bibron & Bory; *yx tataricus helluo* Pallas; *Coluber viridi-flavus* acépède, *Elaphe quatuor-lineata* Lacépède. The authors nclude that Lichtenstein and not Fitzinger must stand author of the genus and sp., *Ablepharus pannonicus*. hey discard *Natrix maura cherseoides* Wagler as a mere ase of *N. maura* (L.) that does not require a name. a footnote they show that *Neoemys* Lindholm is a nonym of *Eurydoidea* Gray, and they criticize Lindlm's division of *Testudo* into subgenera on the basis geographical distribution.

15009. **MIYAMOTO, S.** Über Geckonen als Moskitoinger. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 307. 1-61. 1930.—*Gecko japonicus* and *Hemidactylus bowringii* catch daily respectively from 49 to 59 and om 43 to 48 specimens of blood-engorged ♀♀ of *Culex itigans*.—*E. C. Faust.*

15010. **PIZA, S. de TOLEDO, Jr.** Considerações a espeito da determinação biometrica das especies em phiologia. [Biometric determination of species of nakes.] *Revista Agric.* [*São Paulo*] 5(3/4): 127-141. 930.—The author attempts to show that the determiation of spp. of snakes cannot be based solely upon uch fluctuating morphological characters as the number f rows of scales, the number of sub-caudals, the numer of ventral plates, etc. If these characters are to e taken into consideration it is necessary to make a iometrical analysis of the same.—*S. de T. Piza, Jr.*

15011. **SIMPSON, GEORGE GAYLORD.** Allognathosuchus mooki, a new crocodile from the Puerco formaion. *Amer. Mus. Novitates* 445. 1-16. 6 fig. 1930.—*A. mooki** (p. 2), from upper fossil level, Puerco formaion [Eocene], San Juan Basin, New Mexico, type in Amer. Mus. Nat. Hist., New York, consists of skull, jaws, and most of the skeleton. The generic characters of *Allognathosuchus* are emended. Skull, jaws and dentition are described. Relationships with other late Cretaceous and early Tertiary crocodiles are discussed; *Caimanoidea* is similar but more primitive although later in time. The form is of interest with regard to the Cretaceous-Tertiary transition problem. The structure does not suggest either a molluscan or chelonian diet, although the jaws were unusually powerful and the teeth were adapted anteriorly for grasping and tearing and posteriorly for crushing. Possibly the rise of this short-snouted genus may have been connected with the expansion of mammals.—*A. S. Romer.*

15012. **STRECKER, JOHN K.** Dragons and other reptiles, real and imaginary. *Baylor Univ., Contrib. to Folk-Lore* 3. 1-19. 2 pl. 1929.—A discussion of dragons, sea serpents, heliotropes and other charms, disappearing broods of snakes, charming snakes, etc.

15013. [**STREL'NIKOV, I. D.**] СТРЕЛЬНИКОВ, И. Д. К характеристике адаптивной организации черепа роющихся змей. [Characteristics of adaptive formation of the skull of burrowing snakes.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 69-72. 1930.—The skulls of *Glauconia hamulirostris*, *Typhlops punctatus*, and *Cylindrophis rufus* were studied. Each possesses distinctive adaptations to the same environment (subterranean life), indicating a different origin for these 3 snake families.—*S. A. Corson.*

15014. **TAYLOR, EDWARD H.** The discovery of a lizard Sceloporus torquatus cyanogenys Cope in Texas, new to the fauna of the United States. *Proc. Biol. Soc. Washington* 44: 129-131. 1931.—Full description is given, with discussion of locality and range.

15015. **WIMAN, CARL.** Die Kreide-Dinosaurier aus Shantung. *Geol. Surv. China Palaeontol. Sinica Ser. C* 6(1): 1-67. 9 pl., 7 fig. 1929.—In 1923 two partially complete skeletons of *Helopus* zdanskyi* (p. 6) were discovered at Mêng-Yin-Hsien, China. Specimen (a) consists of vertebrae 2-25, neck ribs and part of breast ribs, fragment of coracoid, and left femur; specimen (b) of vertebrae 22-37, entire pelvis, right femur together with the tibia, fibula, astragalus, metatarsals 1-3, and 7 phalanges. *H. zdanskyi* occupies a unique position paleontologically and though approaching *Camarosaurus* in skeletal structure, esecially in regard to the skull, must yet be placed in a new family, **HELOPODIDAE** (p. 28). There is evidence that *Helopus* led an aquatic existence, walking on the bottom of lagoons, as evinced by the high nostrils, relatively light bones, and the fan-like arrangement of the tarsal phalanges. Arrangement and structure of teeth indicate herbivorous diet. A complete skeleton of *Tanius sinensis** was also found in 1923. *Tanius* falls in the subfamily Hadrosaurinae, and it is thought that *Trachodon amurense* is identical with it. Skeletal features indicate the hydrophilous and herbivorous nature of *Tanius*. The bones of *T. sinensis* are exceedingly porous and this, together with their special modifications, substantiates the genetic affinities of the Orthopoda with the Pterosauria. Fragments of other sauropod remains are described together with those of Theropoda and a caudal spine of a stegosaur. Several turtles were also discovered. The individual parts of all the specimens are minutely described.—*J. Piatt.*

15016. **WOODBURY, ANGUS M.** A descriptive catalog of the reptiles of Utah. *Bull. Univ. Utah, Biol. Ser.* 21 (5): 1-129. 58 fig. 1931 (Biol. Ser. 1(4)).—A brief sketch is given of the history of Utah herpetology. General topics treated in the introduction include habits, sex, enemies, economic value, poisonous forms, and faunal relations. Keys are given to all groups from families to spp. The catalogue treats of 20 lizards, 25 snakes, and 2 turtles. The account of each sp. includes synonymy, description, habits, general range, and distribution within the state. Many spp. are figured. *Pituophis catenifer deserticola* Stejneger (=*P. c. stejnegeri* Van Denburgh); *Tantilla nigriceps* eiseni (*T. e.* Stejneger) (p. 107). Bibliography.

(See also in this issue section Economic Ornithology; and Entries 12254, 12362, 12534, 12630, 12635, 13045, 13119, 13120, 13913)

GENERAL AND POPULAR

15017. **BARCLAY-SMITH, PHYLLIS.** The destruction of birds by oil pollution at sea and the progress made since 1926 in combating this. *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 503-508. 1931.—In addition to destroying many thousands of birds annually, oil pollution at sea results in danger of fire, defilement of beeches, destruction of plankton, and threat to fisheries. The main sources of this pollution are leakages from oil-driven and oil-carrying ships. The

installation of oil-separators on all oil-driven vessels is the best solution of the problem, and their universal adoption is urged.

15018. **CHRISTY, BAYARD H. British birds at a glance.** *Auk* 47(1): 11-21. 1930.—An American bird-lover's impressions of British bird life, especially in comparison with American birds.

15019. **DROST, RUDOLF. Über die Organisation eines Stationsnetzes zur Beobachtung des Vogelzuges im Gebiet der Nordsee.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 324-326. 1931.—Proposals for the organization and operation of a chain of stations for the observation of bird migration in the North Sea region.

15020. **GEYR von SCHWEPPENBURG, H. Zur Terminologie des Vogelzuges.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 333-339. 1931.—The term "Zug" (migration) can not be replaced by "Wanderung" (wandering). "Heimat" (home) is capable of various interpretations. "Wegzug" (departure migration) and "Heimzug" (homeward migration) are proposed as terms of more general applicability than "Herbstzug" (fall migration) and "Frühlingszug" (spring migration). "Übertrockenzeiten" and "Überregenzeiten" are applied to the migration of tropical birds to escape the dry and rainy seasons, respectively; "Überruhezeiten" to the spending of the non-breeding season. "Zwischenzug" (interim migration) is applied to the wandering of herons, etc., between the breeding season and the period of regular fall migration. "Ruheziel" (resting objective) is proposed as a more valid term than winter quarters. The area reached during the interim migration is termed "Zwischenziel" (interim objective). "Auswanderung" (emigration) is applied to a bird's shifting from its natal area to another area for breeding. A bird's actual route between its home and its resting objective is its "Zugweg" (migration route). "Idealzugweg" (imaginary migration route) is represented by a straight line connecting home and resting objective. A convergence of migration routes is referred to as a "Massenzugweg" (general migration route). "Schmalfront" (narrow front) and "Breitfront" (broad front) refer to the lateral extent of the migration of a species. An extensive physiographic formation serving to direct migration is a "Leitlinie" (guide line). "Kennpunkten" (recognized landmarks) guide certain species on definite and regular routes.

15021. **LÖNNBERG, EINAR. [Presidential address.]** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 6-28. 1931.—Comments on various problems of ornithology, including the concepts of "Formenkreis," "Rassenkreis," species, and subspecies, and the effects of environment and isolation in producing subspecies. Also memorial notices of many recently deceased ornithologists, especially E. Lehn Schiöler (Denmark), Robert Ridgway (U. S. A.), Jonathan Dwight (U. S. A.), Emilie Snethlage (Germany and Brazil), Annie Jackson Meinertzhagen (Britain), Herbert C. Robinson (Britain and Malaysia), Peter Petrovitch Sushkin (Russia), Otto von Zedlitz (Germany), and J. Büttikofer (Switzerland and Netherlands).

15022. **PITTET, L. Adlerschutz in der Schweiz.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 519-520. 1931.—The golden eagle is slowly but steadily decreasing in Switzerland. It can be saved only by complete protection during the nesting season.

15023. **SCHOENICHEN, WALTHER. Weiterer Bericht über Vogelschutz in Deutschland.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 513-514. 1931.—In Prussia recent legislation has left only 13 species of birds without protection. A shorter open season or complete protection is accorded to certain game birds. Sale and transportation of birds are forbidden. Bounties and pole-traps for birds of prey are forbidden. Lighthouses are provided with protective devices for birds.

15024. **STADLER, HANS. Elektrophonographische Aufnahmen von Vogelstimmen.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 496-499. 1931.—Description of 2 methods of recording bird voices by means of electrical apparatus.

15025. **THIJSSE, JAC. P. An introduction to the excursions of the International Ornithological Congress to the Naardermeer, the Zwanenwater and the Isle of Texel.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 100-104. 1931.—Account of several bird sanctuaries in Netherlands.

SYSTEMATIC

15026. **CARRIKER, M. A., Jr. Descriptions of new birds from Peru and Bolivia.** *Proc. Acad. Nat. Sci. Philadelphia* 83: 455-467. 1932.—*Pionopsitta melanotis* **peruvianus** (p. 455), *Pipra caeruleo-capilla* **grandior** (p. 456), *Pipreola frontalis* **juninensis** (p. 456), *Muscisaxicola capistrata* **borealis** (p. 457), *M.* **tenuirostris** (p. 458), and *M.* **titicacae** (p. 459), Peru; *Empidonax bolivianus* Allen is removed from the synonymy of *E. traillii brewsteri* Oberh.; *Todirostrum chrysocrotaphum* **neglectum** (p. 460) and *Euscarthmornis granadensis* **caesius** (p. 460), Peru; *Myiophobus* **inornatus** (p. 461), Peru (type) and Bolivia; *M.* **rufipennis** (p. 462) and *Tachurus* [misspelling for *Tachuris*?] *rubrigastra* **grandis** (p. 463), Peru; *Mionectes olivaceus* **viridiceps** (*M. striaticollis v.* Chapman) (p. 463); *Thamnophilus aspersiventer* **steinbachi** (p. 464), Bolivia; *T. aroyae* [here spelled *oroyae*] (Hellmayr), first description of ♀; *Microrhopias quixensis* **albicauda** (p. 465), Peru; *Grallaria andicola* **punensis** (*G. p.* Chubb) (p. 465), emended description; *Chlorophonia torrejoni* Tacz. is maintained as a distinct species; *Sicalis citrina* **occidentalis** (p. 467), Peru. Types of new forms in Acad. Nat. Sci. Philadelphia.

15027. **HARTERT, ERNST, and ERNST MAYR. I. On a collection of birds made by Dr. Ernst Mayr in Northern Dutch New Guinea, by HARTERT. II. My Dutch New Guinea Expedition, 1928, by MAYR. III. List of the birds collected by Ernst Mayr, by HARTERT.** *Novitates Zool.* 36(1): 18-128. 1930.—In part I (pp. 18-19) Hartert briefly reviews previous ornithological explorations in the parts of New Guinea covered by Mayr.—In part II (pp. 20-26) Mayr gives his itinerary and a general account of his field experiences in the Arfak Mts. of the Vogelkop Peninsula, in the Wandammen Mts. and in the Cyclops Mts. near Humboldt Bay.—In part III (pp. 27-128) Hartert gives a systematic account of 352 spp. and subspp., represented by 2700 specimens. This account includes distributional records, taxonomic discussion, and notes on colors of "soft parts" and weight. Two species and 30 subspp. from Mayr's collection and 9 other subspp. are described as new. *Ailuroedus jobiensis* Rothschild is removed from the synonymy of *A. melanotis arfakianus* Meyer; *Amblyornis inornatus* **mayri** (p. 30); *Seleucides melanoleucus* **auripennis** (*S. ignotus a.* Schlüter) (p. 33); *Epimachus fastosus* **stresemanni** (p. 34), type in Tring Mus.; *Diphyllodes magnificus* **intermedius** (p. 36), with review of other subspecies; *Paradisaea m. minor* Shaw, type locality fixed at Arfak; *Phonygammus keraudrenii* (Less. & Garn.), review of subspp.; *Munia* **vana** (p. 42); *M. spectabilis* **mayri** (p. 42); *M. grandis* **destructa** (p. 42); *Erythrura trichroa sigillifera* De Vis (=*E. t. macgillivrayi* Mathews); *E.* **papuana** (*E. trichroa p.* Hartert) (p. 43); *Melilestes megarhynchus* **stresemanni** (p. 45); *Melipotes fumigatus goliathi* R. & H. (=*M. f. anthophilus* Stresemann); *Meliphaga montana* **germanorum** (p. 47); *Xanthotis polygramma* **kuehni** (p. 49); *Ptiloprora guisei* **mayri** (p. 49); *Dicaeum* **geelvinkianum** (p. 51); *Melanocharis* Scl. (=*Urocharis* Salvad.); *Pachycare flavogrisea* **subpallida** (p. 53); *Pachycephala schlegelii* **cyclopum** (p. 54); *P. griseiceps* Gray, review of subspp.; *P. g. jobiensis* Meyer (=*P. g. rubiensis* Meise); *P. g.* **subflavidior** (p. 56); *P. g.* **perneglecta** (p. 56); *P. rufinucha* **niveifrons** (p. 57); *Pinarolestes megarhynchus* **goodsoni** (p. 59), with review of other subspp.; *Pitohui nigrescens* **wandamensis** (p. 59); *P. cristatus* **arthuri** (p. 61), with review of other subspp.; *Gerygone chloronota cinereiceps* (Sharpe) (=*G. placida* Madarász); *G. c. chloronota* Gould

G. c. darwini Math., *G. c. apsleyi* Math.); *G. neglecta* :scens (Blyth) (=*G. n. dohertyi* R. & H.); *G. rubra* iarpe), first description of ♀; *Phylloscopus trivirgatus* lopum (p. 65); *Microeca* Gould (=*Kempiella* th.); *Poecilodryas leucops* **mayri** (p. 67); *P.* **crypto**-:us (p. 67); *P. albonotatus* **correctus** (p. 68); *Pachy-halopsis hattamensis* **ernesti** (p. 69); *Heteromyias ispecularis* **rothschildi** (p. 69), with review of other spp.; *H. a.* **cinereifrons** (*Poecilodryas* ? *c.* Ramsay) 69); *Peltops blainvilli* **montanus** (*P. m.* Stres.) (p. ; *Monarcha axillaris fallax* (Ramsay) (*Piezorhynchus* :henowi Madarász); *Rhipidura threnothorax* S. Müll. =*Setosura t. novae-guineensis* Math.); *R. hyperythra* taneothorax Ramsay (=*R. manayoensis* De Vis); *brachyrhyncha* Schl. (=*R. montana* Math.); *R. a.* olimbata Salvad. (=*R. a. lorentzi* Van Oort); *Malurus* oscapulatus **aida** (p. 78), with review of other sub-ecies; *M. alboscapulatus* **lorentzi** (*M. l.* van Oort) . 78); *Megalurus timoriensis* **stresemanni** (p. 79), :h review of other subspp.; *M. t.* **mayri** (p. 79); *M. t.* icrurus (*Sphenoeacus m.* Salvad.) (p. 80); *M. t.* iboinensis (*Sphenoeacus a.* Salvad.) (p. 80); *M. t.* ilvillensis (*M. alisteri m.* Math.) (p. 81); *Crateroscelis* nfordi (p. 81); *C. robusta* **deficiens** (p. 81); *C. r.* **ninsularis** (p. 82); *C. r. robusta* De Vis (=*C. pec-ralis* R. & H.); *C. r.* **albigula** (*C. a.* Rchw.) (p. 82); *ricornis magnirostris* **cyclopum** (p. 83) with review of her subspp.; *S. perspicillata* **goodsoni** (p. 84); *Aetho-yias spilodera* **granti** (p. 85), type in Tring Mus.; *malocichla i.* **incerta** (*Eupetes incertus* Salvad.) (p.); *A. i.* **brevicauda** (*Drymoedus b.* De Vis) (p. 85); . *i.* **olivascentior** (p. 85); *Drymoedus superciliaris* **bec-rii** (*D. b.* Salvad.) (p. 86); *D. s.* **brevirostris** (*Dry-aoedus b.* De Vis =*Drymodes beccarii adjacens* Math.) . 86); *Eupetes leucostictus* **mayri** (p. 87); the type cality of *Campephaga strenua* Schlegel is fixed at Arfak eninsula; *Pitta atricapilla* **hebetior** (p. 92), Dampier l.; *Collocalia fuciphaga* **mayri** (p. 93); *Aegotheles istata* **affinis** (*Ae. a.* Salvad.) (p. 94); *Ae. albertisi bertisi* Scl. (=*Ae. dubius* A. B. Meyer); *Ae. a. salva-rii* Hart. (=*Ae. rufescens* Salvad.); *Eurystomus orien-lis crassirostris* Scl. (=*E. waigiouensis* Elliot); *Syma rotoro* Lesson, review of subspp.; *S. t.* **megarhyncha** *S. m.* Salvad.=*S. t. wellsi* Math.) (p. 98); *Melidora acrorhina* **waigiuensis** (p. 99); *Halcyon s. sancta* Vig. Horsf. (=*H. sanctus ramsayi* Math., *H. westralasianus* ampbell, *H. sanctus confusus* Math.); *Alcyone azurea ulchra* Gould [1846] and *A. ruficollaris* Bankier [1841] re synonyms; *Tanysiptera sylvia* **mira** (p. 100); *Cen-opus nigricans* (Salvad.) and *C. bernsteini* Schlegel are eparated specifically from *C. spilopterus* Gray; the type ocality of *Chalcopsittacus duivenbodei* Dubois is fixed t Tana Mera, of *Psittacus papou* Scopoli at Arfak, nd of *Trichoglossus josephinae* Finsch at Arfak Mts.; *Charmosyna josephinae* **cyclopum** (p. 104); *Charmo-ynopsis pulchella* **rothschildi** (p. 105); *Opopsitta d. esmarestii* (Desm.) (=*Cyclopsitta d. intermedius* van)ort); *Micropsitta pusio beccarii* (Salvad.) (=*Nasi-erna salvadorii* R. & H.); *Psittacella brehmii* **intermixta** p. 107), type in Tring Mus.; *Megaloprepia magnifica* **nterposita** (p. 114); the type locality of *Peristera rufi-rula* Jacq. & Puch. is fixed at Arfak Peninsula; *Chara-lrius apricarius* **fulvus** (*C. f.* Gmelin) (p. 118); *Iredi-arra gallinacea* Ramsay, review of subspp.; *I. g. novae-iollandiae* (Salvad.) (=*I. g. rothschildi* Math., *I. g. nelvillensis* Math.); *Chlidonias leucopareia fluviatilis* (Gould) (=*C. l. rogersi* (Math.)); *Hypotaenidia philippensis* **meyeri** (p. 121), Witu Isl., Bismarck Arch.; *Rallus pectoralis* **mayri** (p. 121); the name *Porzana tabuensis* **immaculata** (*Gallinula i.* Sw.) (p. 123) is applied to Australian birds, the subspecies described by Mathews being considered indistinguishable; *Gallinula tenebrosa* **neumanni** (p. 123); *G. t.* **frontata** (*G. f.* Wall.) (p. 123); *Fulica atra*, new to New Guinea; *Rallicula rubra* **mayri** (p. 124); *R. r. rubra* Schlegel (=*R. klossi* Ogilvie-Grant); *Synoicus ypsilophorus* **saturatior** (p. 125), with review of other subspp. Unless otherwise stated, types of new forms are from New Guinea, but not exclusively from the Dutch territory, since some of the new forms are based upon collections other than that of Mayr. With few exceptions, the type depository is not given in individual cases, but apparently the type specimens are divided between Tring Mus. and Am. Mus. Nat. Hist.

15028. **HARTERT, ERNST.** Types of birds in the Tring Museum. D. Gregory M. Mathews's types of Australian birds. III. *Novitates Zool.* [*Tring*] 37(1): 35-52. 1931.—Anatidae: *Chenopis atrata* Latham (=*C. a. roberti* Math.); *Anseranas semipalmata* (Latham) (=*A. s. hamiltoni* Math.); *Tadorna tadornoides* (Jardine & Selby) (=*T. t. westralis* Math.); *Spatula clypeata* L. (=*S. c. indiana* Math.); *Malacorhynchus membranaceus* (Latham) (=*M. m. assimilis* Math.); *Nyroca australis* Eyton (=*N. nyroca dampieri* Math.); *Oxyura australis* Gould (=*O. a. victoriae* Math.); *Biziura lobata* (Shaw) (=*B. l. menziesi* Math.). Accipitridae: *Circus assimilis* Jardine & Selby (=*C. approximans inexpectatus* Math., *C. assimilis rogersi* Math.); *C. approximans* Peale (=*C. a. drummondi* Math. & Iredale); *Accipiter novae-hollandiae cooktowni* (Math.) (=*Astur novaehollandiae alboides* Math.); *A. cirrocephalus cirrocephalus* (Vieill.) (=*A. c. quaesitandus* Math.); *Aquila audax* (Latham) (=*Aquila a. carteri* Math.); *Erythrotriorchis radiatus* (Latham) (=*E. r. katherinae* Math., *E. r. queenslandicus* Math.); *Nisaetus m. morphnoides* (Gould) (=*Aquila m. coongani* Math.); *Haliastur s. sphenurus* (Vieill.) (=*H. s. territori* Math.); *Milvus migrans affinis* Gould (=*M. korschun napieri* Math.); *Haliastur indus girrenera* (Vieill.) (=*H. i. subleucosternus* Math.); *Milvus isurus* Gould (=*M. i. westraliensis* Math.); *Elanus notatus* Gould (=*E. axillaris parryi* Math.); *Baza s. subcristata* (Gould) (=*B. s. queenslandica* Math.). Falconidae: *Falco l. longipennis* Sw. (=*F. lunulatus murchisonianus* Math., *F. lunulatus apsleyi* Math.); *Ieracidea b. berigora* (Vigors & Horsfield) (=*I. b. centralia* Math., *I. b. kempi* Math., *I. b. melvillensis* Math., *I. b. tasmanica* Math.); *Falco cenchroides* Vigors & Horsfield (=*Cerchneis cenchroides milligani* Math.). Muscicapidae: *Orthonyx t. temminckii* Ranz. (=*O. t. chandleri* Math.); *Cinclosoma punctatum* (Shaw) (=*C. p. dovei* Math.); *C. cinnamomeum cinnamomeum* Gould (=*Samuela cinnamomea todmordeni* Math.); *Hylacola p. pyrrhopygia* (V. & H.) (=*H. p. belcheri* (Math.); *H. p. cauta* Gould (=*H. p. halmaturina* Math.); *H. cauta* Gould is considered only subspecifically separable from *H. pyrrhopygia* (V. & H.); *Psophodes o. olivaceus* (Latham) (=*P. o. magnirostris* Math.). The author also comments upon a number of other types of Mathews, whose status either is not changed here or has been changed previously.

15029. **HENS, P. A.** Subspeziesfragen in Holland. *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930 439-464. 1931.—The author aims especially to determine the relations between avian subspecies in the Netherlands and in Great Britain, and mentions previous works dealing with this question in the former country. Its fauna has been derived from 3 sources: (1) the North German lowland; (2) the Rhine Valley; (3) southern and southwestern Europe, including an "Atlantic" element. The author discusses in particular 24 "Formenkreise" represented by subspecies in western Europe. Critical determinations of the breeding subspecies of the Netherlands are as follows: *Coloeus monedula spermologus; Garrulus glandarius rufitergum*, intergrading with *G. g. glandarius; Fringilla coelebs hortensis; Certhia brachydactyla megarhynchos; Sitta europaea hassica; Parus m. major; P. cristatus brunnescens; P. palustris longirostris; P. atricapillus subrhenanus; Regulus r. regulus; Turdus philomelus clarkei; Erithacus rubecula monnardi; Dryobates major arduennus; Athene noctua vidalli; Tyto alba rhenana; Haematopus o. ostralegus; Charadrius apricarius oreophilos; Perdix perdix sphagnetorum.* Bibliography.

15030. **JOUARD, HENRI.** Prélude à quelques examens de variabilité subspécifique d'oiseaux de chez nous. *Rev. Franç. Ornith.* 1928(231/232): 210-218. 1928.—A dis-

cussion of criteria in the determination of avian subspecies.

15031. **JOUARD, HENRI. Une nouvelle forme de pic-vert habiterait-elle les Pyrénées-Orientales?** *Rev. Franç. Ornith.* 1928(231-232): 242-253. 1928.—Detailed description of a puzzling specimen of *Picus viridis*.

15032. **JOUARD, HENRI. De la variabilité subspécifique de Parus major dans l'Europe occidentale.** *Rev. Franç. Ornith.* 1928(233): 287-292. 1928.—The author calls attention to slight variations in specimens from Sardinia, Germany, Switzerland, and France.

15033. **JOUARD, HENRI. De la variabilité subspécifique de Parus caeruleus dans l'Europe occidentale.** *Rev. Franç. Ornith.* 1928(234): 311-330. 1928.—A review of 6 subspp. of *P. caeruleus*, with detailed descriptive notes on specimens exhibiting local variation. The validity of *P. c. tourcdauricus* Bacm. & Kleinschm. is questioned. For the birds of France an apparently new name, *P. c.* **exiguus** (p. 330), is introduced without description and without designation of particular type locality or type specimen.

15034. **JOUARD, HENRI. De la variabilité géographique de Parus ater dans l'Europe occidentale.** *Rev. Franç. Ornith.* 1928(235): 355-374. 1928.—A review of 6 previously described subspecies of *P. ater*, with detailed descriptive notes on variations exhibited by specimens from many localities. *P. ater abietum* Brehm (=*P. a. intermedius* Burg) is recognized as a valid subspecies of Germany and Rumania; *P. a.* **burgi** (p. 372), Switzerland, type in author's coll.; *P. a.* **rapinensis** (p. 373), N. & W. France; *P. a.* **parisi** (p. 373), Pyrénées-Orientales, France, type in author's coll.; *P. a.* **mediterraneus** (p. 374), Alpes-Maritimes, France.

15035. **KUHN, OTTO. Die Kennzeichen unserer Taubenrassen. [Characteristics of the common races of doves.]** *Pelztierzucht u. Kleintierzucht* 8(1): 8-13. 11 fig. 1932.

15036. **OBERHOLSER, HARRY C. New birds from Brazil.** *Proc. Colorado Mus. Nat. Hist.* 10(5): [24]-[28]. 1931.—*Accipiter guttifer*, new to Brazil (Matto Grosso); *Uropelia campestris* **figginsi** (p. 24) and *Picumnus* **arileucus** (p. 25), Matto Grosso; *Sicalis pelzelni* **danisa** (p. 28), Matto Grosso (type) and Paraguay. Types of new forms in Colorado Mus. Nat. Hist.

15037. **RILEY, J. H. A second collection of birds from the Provinces of Yunnan and Szechwan, China, made for the National Geographic Society by Dr. Joseph F. Rock.** *Proc. U. S. Nat. Mus.* 80(7): 1-91. 1931.—This is a report on over 1700 specimens, representing 254 forms. The collection was made largely in the semi-independent kingdom of Muli, in southwestern Szechwan, where no birds had been previously collected. Some of the mountains rise to more than 25,000 ft. A list of collecting localities, with altitudes, is given. The systematic account includes locality and date records and descriptive and taxonomic notes. *Lerwa lerwa major*, new to Yunnan; *Hirundapus nudipes* (Hodgson) and *H. caudacutus* (Latham) are treated as separate species; *Calandrella brachydactyla dukhunensis*, new to Yunnan; *Babax l. lanceolatus* (Verreaux) (=*B. l. bonvaloti* Onstalet); *Trochalopteron e. elliotii* Verreaux (=*Trochalopterum yunnanense* Rippon); *Cinclus cinclus beicki* Meise (=*C. c. szetschwanensis* Meise); *Cichloselys s. sibiricus*, new to Yunnan; *Culicicapa ceylonensis calochrysea* Oberh. (=*C. c. orientalis* Baker); *Anthus spinoletta japonicus*, new to Yunnan; *Carpodacus* **murati** (*C. erythrinus m.* Delacour) (p. 75); *Leucosticte* **walteri** (*Montifringilla brandti w.* Hartert) (p. 80). Index.

15038. **SWANN, H. KIRKE, and ALEXANDER WETMORE. A monograph of the birds of prey (order Accipitres).** Part 10. 1-64. 2 col. pl. Wheldon & Wesley, Ltd.: London, 1931.—This part treats of 9 species (with their subspecies) belonging to the genera *Gypaëtus, Uroaëtus*, and *Aquila*. *Gypaëtus barbatus* **hemachalanus** (*Gypaetos h.* Hutton) (p. 5) and *G. b.* **altaicus** (*G. a.* Sharpe) (p. 7) are recognized as distinct subspecies. Keys are given to the genera of Aquilinae and the species of *Aquila*. *Aquila chrysaëtos* **barthelemyi** (*A. b.* Jaubert) (p. 23), *A. c.* **nobilis** (*A. n.* Pallas=*A. fulva kamtschatica* Severtzow) (p. 32) and *A. heliaca* **crassipes** (*A. c.* Brooks) (p. 40) are recognized as distinct subspecies; *A. heliaca* **ricketti** (p. 42), China (type from Fokien, in Brit. Mus.), Siberia, Korea, and Japan; *A. adalberti* L. Brehm is recognized as a distinct species, and *A. clanga* **fulvescens** (*A. f.* Gray) (p. 63) as a distinct subspecies.

LIFE HISTORY

15039. **BAERG, W. J. The song period of birds of northwest Arkansas.** *Auk* 47(1): 32-40. 1930.—A table indicates the extreme dates of the song periods of 76 species, as noted during the years 1924-28. Another list gives the average period during which the more common species sing with regularity. Additional details concerning the song and song periods of certain species are furnished.

15040. **BOWLES, J. HOOPER, and F. R. DECKER. The ferruginous rough-leg in Washington.** *Murrelet* 12 (3): 65-70. 1 pl., 3 fig. 1931.—*Archibuteo ferrugineus* seems confined to the country east of the Cascade Mts. in the State of Washington, inhabiting the driest localities. It builds its nests of dead sticks, lined with soft bark, on low outcroppings of rock or in small trees. The eggs are from two to five. The species is entirely beneficial to man, eating great numbers of mice and other destructive small mammals. It has a habit of putting a large ball of dry horse or cow manure in the nest with the eggs. The sitting bird sometimes will not leave her eggs unless forced from them. The magpie (*Pica pica hudsonia*) often nests in the same tree, living in perfect harmony with the hawks.—*J. H. Bowles*.

15041. **CHAPPELLIER, A. Les baguages de freux (Corvus frugilegus Linné) du Service des Vertébrés, du Centre National de Recherches Agronomiques de Versailles, et leurs premiers résultats.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 320-323. 1931.—The breeding area of rooks (*Corvus frugilegus*) in France is chiefly north of the Loire. Recoveries of those banded as nestlings indicate that the individuals breeding in this country are sedentary there, although they leave the immediate vicinity of the rookeries after the breeding season. Of immigrants from the east, banded in the fall in east central France, all recoveries in France have been from south of the Loire; there have also been several very puzzling winter recoveries in Jugoslavia and Germany.

15042. **DOBAY, LAD. Der Brutparasitismus des Kuckucks, mit besonderer Rücksicht auf die siebenbürgischen Verhältnisse.** *X^e Congr. Internat. Zool. à Budapest 1927. Part 1.* 839-856. 1929.—Thirty-two years of personal experience with cuckoos are summed up and critical observations detailed. It is concluded that cuckoos place their eggs in certain nests, not because of location, but because the nests belong to species of like kind that are most certain to successfully raise cuckoos. Females lay in nests of species by which they were raised and their breeding seasons coincide with those of these species. It is believed that the laying period depends on the general condition and food supply of the cuckoo, not on stimulation by the nuptial activities of other species as claimed by Chance. Eggs are regularly laid on the ground and placed in the nests with the bill, contrary to Chance's observations. Cuckoos watch over nests containing their eggs, and if conditions become unfavorable may move the eggs to other nests. Inability to provide food for the normally large number of cuckoo young and the problem of keeping the eggs in condition during the completion of a large set are factors which have necessitated development of a parasitic habit out of originally normal breeding behavior.—*A. H. Miller*.

15043. **HEIM de BALSAC, H. Mode de nidification inaccoutumé chez Buteo b. buteo (L.).** *Rev. Franç. Ornith.* 1928(235): 395-396. 1928.—Nest in a roadside tree far from any woods, which constitute the normal nesting habitat.

15044. **HEINROTH, O. Beobachtungen bei der Aufzucht vom Purperreiher, Ardea purpurea, vom Löffler,**

Platalea leucorodia, und vom Säbelschnäbler, Recurvirostra avosetta. *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 493-495. 1931.—Notes on development, voice, and behavior of young reared in captivity.

15045. **HUXLEY, J. S. Biology of bird courtship.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 107-108. 1931.

15046. **LÖNNBERG, EINAR. The migration of the woodcock, Scolopax rusticola L., from Sweden. (A summary.)** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 389-391. Map. 1931.—Individuals banded in central Sweden have been taken in Scotland and Ireland, doubtless having crossed directly over the North Sea. Another record from northern France suggests a secondary movement from the British Isles to France. Individuals banded in southern Sweden evidently pursue a more southerly route, several having been taken in southern England and northern France.

15047. **LUCANUS, FR. von. Die Zugwege des weissen Storchs und des Schwarzstorchs.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 327-332. 1931.—*Ciconia ciconia* now avoids the wide stretch of the Mediterranean by pursuing 2 migration routes, one around each end of this sea. But in 1856 a great number were destroyed by a storm while on migration across this sea in the vicinity of Malta. Since then the route through Italy has been practically abandoned. *Ciconia nigra* has the same two migration routes, but prefers the western one, while *C. ciconia* follows the eastern one in far greater numbers. *C. nigra* also follows the Italian route across the Mediterranean to some extent.

15048. **MICHAEL, ENID. Feeding habits of the woodpeckers in the Yosemite valley.** *Yosemite Nature Notes* 10(12): 99-101. 1931.—Notes on *Sphyrapicus varius daggetti*.

15049. **REBOUSSIN, R. La gorge-bleue Luscinia svecica cyanecula (Wolf.), en Vendée.** *Rev. Franç. Ornith.* 1928(234): 343-345. 1928.—Notes on nesting, song, and courtship.

15050. **ROTHSCHILD, [L. W.]. Notes on paradisaeidae with a list of the species, subspecies, and hybrids exhibited at the Seventh International Ornithol. Congress.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 285-289. 1931.—The author calls attention to the characteristic types of nests and eggs of this family. A list is given of the birds exhibited, including 34 forms of Ptilinorhynchinae, 70 Paradisaeinae, and 16 supposed hybrids.

15051. **SCHÜZ, E. Ergebnisse der Vogelberingung.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 293-319. 16 maps. 1931.—The number of birds banded by nearly 30 stations and their collaborators in Europe, Asia, and N. America amounted by 1927 to a million; the number of recoveries, to more than 30,000. Some of the more striking results are here summarized. The percentage of returns for small birds is far less than 1; for large birds and game birds, much greater (e.g., up to 24% for *Ciconia nigra* and 69% for *Accipiter gentilis*). The general direction of fall migration in central and northern Europe is SW.; *Cuculus canorus, Lanius c. collurio,* and *Ciconia ciconia* are exceptional in going SE. *C. ciconia* is noteworthy in having two migration routes, one around each end of the Mediterranean. Direction and choice of route, objective, and restriction of winter range on the part of species or certain populations of given species, are discussed. Ten different breeding populations of *Larus r. ridibundus* are shown to mingle more or less during the non-breeding season, yet the total range of each population differs more or less from that of the others; e.g., the members of Russian and Hungarian breeding colonies do not seem to meet those of a British breeding colony at any time of year. Various populations of *Sturnus vulgaris* show a similar and even more pronounced condition. Birds with this sort of distribution have far greater prospects of separation into geographical races than those whose populations mingle more thoroughly during the winter.

15052. **SKOVGAARD, P. Zug der Islaendischen Vögel und anschliessende Bemerkungen über den Vogelzug in Europa.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 392-405. 8 maps. 1931.—Since 1921, 4464 birds of 47 species have been banded in Iceland. The author presents records of 125 recoveries, chiefly in the British Isles and continental Europe, with a few in Africa and North America. The migration of some individuals of *Anas penelope* to North America, instead of to the main winter quarters in Europe, is especially striking. This, together with the case of 4 young of *Ciconia nigra* from the same nest in Denmark, 2 of which migrated SE. and 2 SW., contradicts the theory that migration routes correspond to the old routes of immigration, and suggests that migration routes are learned and not inherited.

15053. **STADLER, HANS. Die Stimmen des Wasserpiepers (Anthus sp. spinoletta (L.)).** *Verhandl. Ornithol. Ges. Bayern* 18(1/2): 107-131. 1929.—A detailed analysis of the song of this pipit, richly illustrated with diagrams and musical notations, and comparison with the songs of related species. The call-notes also are described.

15054. **THOMSON, A. LANDSBOROUGH. On "abmigration" among the ducks: an anomaly shown by the results of bird-marking.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 382-388. 1 fig. 1931.—Abmigration is a spring movement which is not the counterpart of any preceding autumn movement. Numbers of ducks of 5 species, banded as native birds in the British Isles, have been subsequently found in summer in Germany, Denmark, Norway, Sweden, Finland, and Russia. This abmigration of individuals may be explained on the assumption that they become attached to flocks of winter visitants and accompany them on their normal emigration in spring.

15055. **TOWNSEND, CHARLES WENDELL. The post-breeding northern migration of North American herons.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 366-369. 1931.—"There seems to be a wanderlust in young herons which appears but slightly in the adults, and this casual wandering in search of food may in past ages have become an inherited instinct for northern post-breeding migration which still shows itself in the young, but has largely faded out in the adult."

15056. **TRISTAN, de. La nidification en Sologne de le sterne moustac Chlidonias l. leucopareia (Tem.), du grèbe à cou noir Podiceps nigricollis Sundevall, et de quelques autres espèces.** *Rev. Franç. Ornith.* 1928 (231/232): 219-226. 1928.—Notes on the nesting of these and other marsh birds in central France.

LOCAL AND FAUNISTIC

15057. **BARTELS, E. Vogels van Kole Beres. [Java.]** *Natuurkundig Tijdschr. Nederlandsch-Indië* 91(3): 308-348. 1931.—An annotated list of 184 species observed from 1927 to 1929 in this area (altitude 600-1000 m.) in SW. Java. Among them, at least 155 are breeding species, and 16 are winter visitors from northern Asia. Many notes on frequency, general habits, and nesting are included.

15058. **HEIM de BALSAC, H. Exploration ornithologique dans le Sud-Oranais et le Maroc Oriental.** *Rev. Franç. Ornith.* 1928(230): 174-188; (231/232): 227-237; (233): 279-286. 1928.—This is a report on an expedition to parts of the Saharan Atlas in western Algeria and eastern Morocco in 1927. In the Dept. of Alger the Saharan fauna begins abruptly on the southern slope of the Saharan Atlas, but in Oran it invades the High Plateaus on the north, extending considerably farther north than the typical Saharan flora. The zonal distribution of vegetation and avifauna on some of the mountains, including the highest peak (Dj. Aïn-Aissa, 2250 m.), is described. The avifaunas of 2 different sections of the Saharan Atlas (in Oran and Alger) are compared. The following are recorded as new to Morocco: *Rhamphocorys clot-bey, Alaemon alaudipes, Ammomanes phoenicurus, Chersophilus duponti, Lanius excubitor elegans, Scotocerca inquietus, Oenanthe leucopyga, O. lugens, Caprimulgus aegyptius, Athene noctua*

saharae, Pterocles coronatus, Alectoris barbara spatzi. An annotated list treats of 47 spp. whose variation or distribution are of particular interest.

15059. **JOUARD, HENRI. Contribution à l'ornithologie des Alpes valaisannes. Les oiseaux du plateau de Montana-Vermala.** *Bull. Murithienne Soc. Valaisanne Sci. Nat.* Fasc. 48. 94-143. 1 pl. 1930-1931.—After a general discussion of the birds of the various seasons, a classified list is given with synonymy and descriptions. Appended is a note on the relation between the bird fauna and the altitude.

15060. **JOUARD, HENRI. Encore quelques mots sur la distribution du cini en France.** *Rev. Franç. Ornith.* 1928(235): 391-393. 1928.—Notes on the local distribution of the serin (*Serinus canarius serinus*).

15061. **KURODA, N. Distribution of the Japanese birds.** [In Japanese.] *Bull. Biogeogr. Soc. Japan* 1(1): 27-35. 1929.—An accompanying map indicates 13 faunal areas.

15066. **MOMIYAMA, TOKU T. On the birds of Bonin and Iwô [=Volcano] Islands [Micronesia].** [Mainly in Japanese.] *Bull. Biogeogr. Soc. Japan* 1(3): 89-186. 2 col. pl. 1930.—A faunal list with extensive synonymies and reviews of previous records. A table shows the distribution of 128 species in 14 different regions in the Japanese Empire, the Philippines, Micronesia, and the Sandwich Isls. Certain related forms of adjacent regions (from Siberia to India, the E. Indies, and the South Seas) are listed and discussed. *Chloris sinica* **seebohmi** (p. 103), Volcano Isls.; *Apalopteron familiare,* col. plate; *Zosterops japonicus* **ohsimensis** (p. 172), Seven Isls., Japan; *Z. j.* **dageleticus** (p. 172), Dagelet Isl., Sea of Japan, type in Seoul Higher Common School; *Horornis cantans* **ponafidinicus** (p. 175), Seven Isls.; *Monticola philippensis* **taivanensis** (p. 177), Formosa. Types in author's coll. unless otherwise stated.

15067. **PAREL, ANDRÉ. Nidification de cigognes dans la Somme.** *Rev. Franç. Ornith.* 1928(230): 197-198. 1 fig. 1928.—Unusual breeding record of *Ciconia c. ciconia.*

15068. **RENSCH, BERNHARD. Der Einfluss des Tropenklimas auf den Vogel.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 197-205. 1931.—Tropical bird races are smaller than the races of the same species living in cooler regions (Bergmann's law); perhaps this is a direct effect of the external temperature in the poikilothermous condition of early life. Tropical races have relatively longer wings than the races of cooler regions; possibly in the case of the latter there is direct checking of growth of the exposed parts under the influence of the lower external temperature. The relative weight of the heart is smaller in tropical birds than in closely related species or races of equal weight in cooler regions. Among omnivorous feeders, tropical races have a relatively smaller stomach, shorter intestine, and shorter caecum than the races of cooler zones. Tropical races have a smaller number of eggs than races of the same species in cooler regions; this rule also applies generally to the species within a genus. This is a matter of adaptation to the shorter day-length in the tropics, or of compensation for the stronger climatic selection in the cooler regions. The melanin (especially eumelanin) of birds is increased in a humid, warm climate (Gloger's law). Strong intensification of melanin may produce expansion of the barbules and thereby give rise to iridescent colors. In the humid, warm tropics the number of bird species is greater than in equal areas in the temperate zones, but the number of individuals of the separate forms is relatively smaller; this phenomenon is evidently due to the more varied environmental conditions and the better conditions of existence in the tropics, which favor the formation and maintenance of species. In cooler zones a more rigorous climatic selection takes place during the winter period. —*From author's summary.*

15069. **WEIGOLD, H. Der Vogelzug auf Helgoland, graphisch dargestellt.** *Proc. 7th Internat. Ornith. Congress Amsterdam* 1930: 406-410. 1931.—Abstract.

MAMMALIA

(See also in this issue Entries 12097, 12159, 12437, 12567, 12630, 12635, 13546, 14241, 14271, 14299, 14303, 14331, 14344, 14367, 14368, 14372, 14402, 14462)

15070. **AIRAGHI, CARLO. Considerazioni filogenetiche sui rinoceronti d'Europa. [Phylogenetic considerations on the rhinoceroses of Europe.]** *Riv. Italiana Paleont.* [*Pavia*] 32(1/3): 23-46. 1 pl. 1 fig. 1926.—After some critical remarks on the previous attempts of classification the author defines a new index which is thought to have taxonomic value. In both skull and mandible it is the ratio between two lengths measured upon a straight line drawn through the grinding surface of the cheek teeth: (a) in the skull—from the anterior border of the glenoidal cavity to the foremost point of the foremost incisor, and the distance from the same point of the glenoidal cavity to the posterior border of the third molar; (b) in the mandible—the distance from the anterior border of the condyle to the foremost point of the foremost incisor, and the distance from the same point of the condyle to the posterior border of the third molar.—The European rhinoceroses are divided into three genera, viz. *Diceros, Rhinoceros,* and *Diceratherium. Diceros* is made to comprise all forms with two median horns, and is divided into three branches: the first with well developed lower canines and an index between 4 and 3.5; the second branching off from the first at the end of the Miocene and having an index between 3.5 and 3; the third branching off from the second during the Pliocene and containing the largest forms without either incisors or canines, with the anterior horn of great length and an index of 3-2.5. *Rhinoceros* contains large Oligocene forms without horns, previously ascribed to *Aceratherium,* and the living forms with one horn. It is divided into two branches; for the first no precise index has been established; in the second it varies between 3.5 and 3. *Diceratherium* contains the forms with two laterally placed horns, and their ancestors without horns, i.e., small Oligocene forms without diastemata between canines and premolars. *Diceratherium* is divided into two branches, one with the index 4-3.5, the other with 3.5-3.—*O. Zdansky.*

15071. **AMSCHLER, WOLFGANG. Über Capra aegagrus und Capra falconeri als Hausziegen im Kaukasus, eine Vorarbeit zur genetischen Bearbeitung der Hausziegen. (Done under the auspices of the "Notgemeinschaft der Deutschen Wissenschaft.")** *Wiss. Arch. Landwirtsch. Abt. B. Tierernähr. u. Tierzucht* 3(2): 307-338. Map. 13 fig. 1930.—On his Caucasian expedition in 1926-1927 the author made extensive studies on domestic

goats and, aside from the very prevalent *Capra prisca*, found a rare form of *C. aegagrus*. Entirely new is the discovery of various *falconeri* types as domestic goats in the Caucasus. The area of distribution of *C. falconeri* as a domestic goat is Daghestan, Ossetia, and certain parts of eastern Transcaucasia. The domesticated *C. aegagrus* greatly resembles the Bezoar goat in shape and position of horns. The study revealed the completely new fact, that the domesticated *falconeri* markedly differs from the wild *falconeri* in its more steeply rising horns with differently shaped cross-section. Several types can be distinguished according to torsion of the anterior and posterior borders: (a) both front edge and posterior surface participate in the spiral (eastern Transcaucasia and Daghestan); (b) the posterior rounded surface remains perpendicular, while the front edge winds about it (eastern Daghestan); (c) the spiral combines features of (a) and (b); (d) the spiral has several twists, combining (a) and (b). Wild individuals of *falconeri* also vary markedly in skull formation. The author does not agree with the opinion that the domestic *falconeri* sprang from existing wild forms.—*Author's summary (transl. by B. Bickel).*

15072. ANTHONY, R. Discussion sur l'interprétation de la série dentaire inférieure du Stehlinius uintahensis Matth. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(6): 416-421. 2 fig. 1928.—*Stehlinius* and related forms are allocated to the Insectivora, their resemblance to the Chiromyiformes being attributed to convergence. The author suggests that the remarkable second tooth in the lower mandible of *Stehlinius* represents a fusion of the 3rd and 4th premolars.

15073. ARAMBOURG, C. Les mammifères quaternaires de l'Algérie. *Bull. Soc. Hist. Nat. Afrique du Nord.* 20 (3): 63-84. 1 pl. 1929.—The Quaternary mammalian fauna of Algeria is somewhat different from that of Europe because in Mousterian time climatic differences and geographic barriers prevented the free interchange of animals between the two regions. The Algerian fauna remained remarkably uniform throughout the Quaternary as a result of the equable climate; boreal mammals seem not to have invaded this region. Moreover, the Algerian fauna was distinctly Ethiopian both in character and origin. Africa was undoubtedly a distinct faunal province in the Quaternary. The migration or disappearance of mammals from the Algerian region was due to climatic changes, to biologic causes (such as a climax in evolutionary development), and to the conquest of nature by man.—*E. H. Colbert.*

15074. ARAMBOURG, C., et J. PIVETEAU. Les vertébrés du Pontien de Salonique. *Ann. Paléontol.* 18(2/3): 3-82. 12 pl., 8 fig. 1929.—During French military operations near Salonika, Macedonia, a large collection of vertebrate fossils was obtained from the Pontian sediments (Upper Miocene). This collection is preserved in the National Mus. Nat. Hist., Paris. The following fauna is described: (Reptilia) *Testudo** spp.; (Carnivora) *Ictitherium robustum**, *I. hipparionum**, *Hyaena eximia**, *Felis* cf. *attica**, *Machairodus aphanistus**; (Soliped) *Hipparion gracile**; (Perissodactyla) *Aceratherium* sp., *Rhinoceros pachygnathus**, *Chalicotherium* cf. *goldfussi**; (Artiodactyla) *Sus erymanthius**; (ruminants) *Dorcatherium* **puyhauberti*** (p. 34), *Giraffa attica**, *Orasius speciosus**, *Helladotherium duvernoyi**, *Gazella deperdita**, *G. gaudryi**, *G.* **bailloudi*** (p. 48), *Protoryx carolinae**, *Tragocerus amaltheus**, *Helicotragus rotundicornis**, *Oioceros rothi**, *Tragelaphus* sp., *Palaeoreas lindermayeri**, *Palaeoryx pallasi**, *Parabos* **macedoniae*** (p. 61); (Proboscidia) *Mastodon pentelici**; (Primates) *Mesopithecus pentelici.* This fauna, like the other Pontian assemblages, has its closest modern relatives among the mammals of Africa, while characteristic Palaearctic forms do not appear until the Pliocene. The various Pontian faunas resemble each other in broad features, but some have peculiar elements.—*L. S. Russell.*

15075. ASTRE, GASTON. Anthracotherium magnum à Saint-Nazaire-de-Valentane. *Bull. Soc. Hist. Nat. Toulouse* 59(1): 153-154. 1930.—Records the finding of a skeleton in the "mollases stampiennes de l'Agenais" at 3½ m. depth.

15076. BARBOUR, EDWIN H. Ancient elephants of Nebraska. *Pan-Amer. Geol.* 53(1): 39-40. 1930.—The Tertiary sections of Nebraska are rich in mammalian remains, 20 proboscideans having been unearthed in Nov., 1929, alone. The oldest Nebraska elephants are the tetrabelodonts, possessing low brows, long jaws, and frames more rugged and bones more massive than those of modern elephants. The largest form is *Megabellodon lulli*, whose mandible and tusks exceed 6 ft. in length. The smallest is *Enhelodon marrilli*, in which the mandibular tusks are lacking. The amebelodonts, shovel-tuskers, found in this region are very massive, the mandible being close to 7 ft. in length. The type specimen, *Amebelodon fricki*, was discovered in south central Nebraska in 1927. Its mandibular tusks are each 4 ft. long, almost straight, very large, and flattened at the tips into great dental shovels. Other spp. from this region are *Amebelodon gregori*, *Archidiskodon hayi*, with but 8-9 grinding ridges in its molars, *Ar. scotti*, *Ar. maibeni* and the hairy mammoth, *Elephas primigenius*. The author remarks that, although over 300 spp. of fossil elephants have been found in various parts of the world, out of this number only 2 genera survive today, represented by the Indian elephant, *Elephas indicus*, and the African elephant, *Loxodonta africana*. —*D. J. MacNeil.*

15077. BEAUX, OSCAR de. Collezioni zoologiche fatte nell' Uganda dal Dott. E. Bayon. XIX. Mammiferi. Parte IV. Appendix, cum primatibus, insectivoris carnivorisque. *Ann. Mus. Civ. Storia Nat. Genova* 52: 100-107. 1925 [1928.—A list of spp. with records, including 1 Primate, 23 Chiroptera, 6 Insectivora, 4 Carnivora, 20 Rodentia, and 19 Ungulata, some with descriptive notes.

15078. BERNSEN, J. J. A. The geology of the Teglian clay and its fossil remains of Rhinoceros. 109p. 12 pl. Dissertation. Univ. Amsterdam. 1927.—The Teglian clay (Tegelen near Venlo in the Netherlands) has yielded a rich flora and mammalian fauna. The question of the geological age—Pliocene or Pleistocene—has given rise to a mass of literature. In the geological part, the arguments for and against the Upper Pliocene age are criticised and in the paleontological part a beginning is made with the paleontological investigation of the remains of the Mammalia found. It is evident now that 2 spp. of *Rhinoceros* occur in the Teglian clay, viz., *R. etruscus* Falconer and *R. mercki* Jäger.—*J. J. A. Bernsen.*

15079. [BIRULIA, A. A.] БИРУЛЯ, А. А. 15085. **DREVERMANN, F.** Ein bemerkenswertes Skelett eines grossen ausgestorbenen Faultieres. *Ber. Senckenberg. Naturforsch. Ges.* [*Natur u. Mus.*] 60(12): 553-556. 2 fig. 1930.—Nontechnical account of *Nothrotherium shastense**, Texas, in the Peabody Mus., Yale Univ.

15086. **DUBOIS, GEORGES.** Marte de la tourbe de Marquion. *Ann. Soc. Geol. du Nord* 52: 280-285. 5 fig. 1927.—A new find of *Martes martes* L. from the peat bogs (Flandrian) of Marquion (Pas-de-Calais) in the valley of the Gâche, northern France.—*W. Berry.*

15087. **DUBOIS, GEORGES.** Additions à la connaissance de la brèche à Lemmings de Maubeuge. *Ann. Soc. Geol. du Nord* 52: 315-322. 3 fig. 1927.—Redescription of *Dicrostonyx torquatus* v. **henseli** (*D. henseli* Hinton) (p. 315), and discussion of a find of *Lemmus lemmus**, both from the north of France.—*W. Berry.*

15088. **DUBOIS, G., et G. PONTIER.** Description de la molaire de lait d'Elephas primigenius trouvée à St. Druon, près Cambrai [northern France]. *Ann. Soc. Geol. du Nord* 53: 112-115. 1 pl. 1928.

15089. **DYBOWSKI, B.** Zur Kenntnis der Sibirischen Seehunde. *Bull. Internat. Acad. Polonaise Sci. et Lett. Cl. Sci. Math. et Nat., Sér. B: Sci. Nat. (II)* [*Zool.*] 1929(8/10): 405-415. 3 pl. 1929.—The author gives a systematic review of the seals hitherto known as *Phoca annellata* (Baltic Sea), *P. saimonensis* (Lake Saima, Finland), *P. ladogensis* (Lake Ladoga, Russia), *P. caspica* (Caspian Sea), and *P. sibirica* (Lake Baikal). The characters of the skull and the pelage are discussed in detail. New family, supergeneric (?), generic, subgeneric (?), and specific names are introduced for all of these forms, without regard to the law of priority. For the 2 forms of Lakes Baikal and Oron, Siberia, the following names, of generic or approximately generic rank, are employed: **SIBIRICO-BICUSPIDATO-BAICALOPUSA** (p. 414), **SIBIRICO-BAICALOPUSA** (p. 405), **BAICALOPUSA** (p. 405), **SIBIRICO-ORONOPUSA** (p. 405), and **ORONOPUSA** (p. 405). The corresponding species are named *Baicalopusa* (or *Sibirico-bicuspidato-baicalopusa*) **dorohostaiskii** (p. 412) and *B.* (or *S.*) **wereschtschagini** (p. 412), but which name applies to the seal of Lake Baikal, and which to the seal of Lake Oron, is not stated. The family name **SIBIRICOPUSIDAE** (p. 412) or **SIBIRICO-BICUSPIDATO-BAICALOPUSIDAE** (p. 414) is employed for the above-mentioned group of Siberian forms. For 3 European species the following new names are introduced: *C.* [initial not explained] **behningi** (p. 414), *C.* **kisielewitschi** (p. 414), and *C.* **dierzawini** (p. 414), but no type localities are given, and it is not explained to which of the older names each of the 3 new names corresponds. The family name **EUROPÄOPUSIDAE** (p. 412) or **EUROPAEO-TRICUSPIDATO-CASPIOPUSIDAE** (p. 414) is employed for this group of 3 European forms. Several other new terms, of indefinite rank and partly of uncertain spelling (owing to the use of abbreviations), are applied (pp. 405 and 412) to 4 European forms, but are not listed in this abstract. None of the new names is labeled as such, and there is no synonymy and no bibliography. [Cf. B. A. 1: 13813 and Opinion 105 of the International Commission on Zoological Nomenclature.]

15090. **EDGAR, J. H.** The haunts of the giant panda. *Jour. West. China Border Res. Soc.* 3: 29. 1926/29[1930].—A record of this sp. from Szechwan more than 4000 years ago.

15091. **FINLAYSON, H. H.** Notes on some South and Central Australian mammals. Pt. 1. *Trans. and Proc. Roy. Soc. So. Australia* 54: 177-180. 1930.—*Petaurus breviceps* is recorded as new to S. Australia. *Thylacomys lagotis* is reinstated as a member of the fauna of Central Australia. Variation in the pelage and skull of *Petrogale lateralis* is discussed.

15092. **FORMOZOW, A. N.** Ueber die Säugetiere der nördlichen Mongolei. *Folia Zool. et Hydrobiol.* [*Riga*] 3(1): 41-78. 1931.—This report is based upon a collection of over 300 skins made by an expedition of the Russian Academy of Sciences in 1926, from the Altai Mts. northward. The systematic list of 44 spp. includes notes on distribution, taxonomy, habits, food, enemies, breeding, etc. *Cricetulus furunculus* **griseus** (*Cricetus g.* A. M. Edw.) (p. 58); *C. f.* **obscurus** (*Cricetus o.* A. M. Edw.) (p. 58); *C. f.* **fumatus** (*C. griseus f.* Thos.) (p. 58); *C.* **curtatus** (*C. migratorius c.* Allen) (p. 61); *Cricetiscus* Thos., reduced to subgeneric rank under *Phodopus* Miller; *Phodopus congarus* **campbelli** (*Cricetulus c.* Thos.) (p. 61); *P. roborovskii* Satunin (=*Cricetulus bedfordiae* Thos.); *Microtus gregalis raddei* Pol. (=*M. angustus* Thos.); *Alticola* **semicanus** (*Microtus worthingtoni s.* Allen) (p. 67); *Ellobius talpinus* **larvatus** (*E. l.* Allen) (p. 69).

15093. **FORMOZOW, A. N.** Notizen über einige Nager des westlichen Kaukasus mit Beschreibungen zweier neuer Formen. *Folia Zool. et Hydrobiol* [*Riga*] 3(1): 79-84. 1931.—*Sicista montana* **strandi** (p. 79); *Chionomys nivalis* **nenjukovi** (p. 81); both from No. Caucasus. *Dyromys nitedula* aff. *nitedula* is recorded also.

15094. **HUEY, LAURENCE M.** A new subspecies of Peromyscus from the gulf coast of Lower California, Mexico. *Trans. San Diego Soc. Nat. Hist.* 6(26): 389-390. 1931.—*P. crinitus* **pallidissimus** (p. 389), type in San Diego Soc. Nat. Hist.

15095. **KRETZOI, NIKOLAUS.** Materialien zur phylogenetischen Klassifikation der Aeluroïdeen. *X. Congrès Internation. Zool. Budapest, 1927.* Pt. 2. pp. 1293-1355. 2 pl. 1929.—The author undertakes a revision of the spp., genera, and higher groups of Aeluroïdea, both recent and fossil. He also discusses the position of the Aeluroïdea in the system of the Ferae, giving a provisional classification of the entire order. The paper ends with remarks on the phylogeny, origin, and distribution of the aeluroid stock. Diagnoses are given of the genera and higher groups. The systematic account of the spp. includes synonymies, information as to type specimen, type locality, and geological horizon, and descriptive and taxonomic notes. The following are new: *Ailurictis* **helbingi** (p. 1295), France, Middle Stampian, type in Basel Mus.; *A.* **jourdani** (p. 1295), France, Vindobonian, type in Mus. Hist. Nat. Lyon; **HYPERAILURICTIS** [Nimravidae] (p. 1295), near *Ailurictis*, type *H. intrepida* **sinclairi** (*Pseudaelurus intrepidus s.* Matthew) (p. 1296), including also *H.* **marshi** (Therpe), n. comb. (p. 1296); **AFROSMILUS** [Nimravidae] (p. 1296), compared with *Ailurictis*, type *A.* **africanus** (*Pseudaelurus a.* Andrews) (p. 1296); **SIVASMILUS** [Nimravidae] (p. 1296), near *Afrosmilus*, type *S.* **copei** (p. 1297), India, Middle or Upper Miocene, type in Geol. Surv. India; **PROPONTOSMILUS** [Nimravidae] (p. 1297), near *Sivasmilus*, type *P.* **sivalensis** (*Pseudaelurus s.* Lydekker) (p. 1298); **PONTOSMILUS** [Nimravidae] (p. 1298), type *P.* **orientalis** (*Machairodus o.* Kittl) (p. 1300), including also *P.* **ogygius** (*Felis ogygia* Kaup) (p. 1299), *P.* **hungaricus*** (*Machairodus h.* Kormos) (p. 1299), *P.* **schlosseri** (*Machairodus s.* Weithofer) (p. 1299), and *P.*

indicus (p. 1300), India, Pontian, type in Geol. Surv. India; *Paramachaerodus* Pilgrim, emended diagnosis; *P.* **pilgrimi** (p. 1301), India, Pontian, type in Geol. Surv. India; **METADEINIKTIS** [Machairodontidae] (p. 1303), near *Dinictis* Leidy, type *M.* **cyclops** (*Dinictus c.* Cope) (p. 1304); *Eusmilus* **schlosseri** (p. 1305), France, Aquitanian, type in München Mus.; **PAREUSMILUS** [Machairodontidae] (p. 1305), near *Eusmilus* Gervais, type *P.* **filholi** (p. 1305), France, Upper Eocene, type in Brit. Mus.; **ALBANOSMILUS** [Machairodontidae] (p. 1306), similar to *Ischyrosmilus* Merriam, type *A.* **jourdani** (*Machairodus j.* Filhol) (p. 1306); **SANSANOSMILUS** [Machairodontidae] (p. 1307), resembling *Albanosmilus* Kretzoi, type *S.* **palmidens** (*Felis p* Blainv.) (p. 1307); *Megantereon* Croizet & Jobert and *Drepanodon* Bronn, emended diagnoses; *Drepanodon* **mehelyi** (p. 1310), Hungary, Upper Pliocene, type in Kgl. Ung. Geol. Anstalt; **TOSCANIUS** [Megantereontidae] (p. 1309), provisionally proposed, type *Ursus cultridens* Cuvier; **EPIMACHAIRODUS** [Machairodontidae] (p. 1310), resembling *Ischyrosmilus* Merriam, type *E.* **hungaricus*** (p. 1311), Hungary, Upper Pliocene, type in Kgl. Ung. Geol. Anstalt, including also *E.* **crenatidens** (*Machairodus c.* Fabrini) (p. 1311), *E.* **latidens** (*Machairodus l.* Owen) (p. 1312), and *E.* **boulei** (p. 1312), France, Upper Pliocene; **PROTAMPHIMACHAIRODUS** [Machairodontidae] (p. 1316), type *P.* **maximiliani** (*Machairodus m.* Zdansky) (p. 1316); **AMPHIMACHAIRODUS** [Machairodontidae] (p. 1316), resembling *Machairodus*, type *A.* **palanderi** (*Machairodus p.* Zdansky) (p. 1317), incuding also *A.* **tingii** (*Machairodus t.* Zdansky) (p. 1317); **AILUROMACHAIRODUS** [Ailuromachairodontidae] (p. 1319), type *A.* **quadridentatus** (*Felis quadridentata* Blainv.) (p. 1319); **PARAPSEUDAILURUS** [Felidae] (p. 1322), near *Pseudaelurus* Gervais, type *P.* **osborni*** (p. 1322), Hungary, Upper Sarmatian, type in Kgl. Ung. Geol. Anstalt, including also *P.* **gaillardi** (p. 1322), France, Vindobonian, type in Mus. Hist. Nat. Lyon; **ELMENSIUS** [Felidae] (p. 1323), resembling *Neofelis* Gray, type *E.* **stehlini** (p. 1323), Germany, Lower Miocene, type in Senckenberg Mus.; **SIVAPANTHERA** [Felidae] (p. 1324), type *S.* **lydekkeri** (p. 1324), India, Upper Pliocene, type in Brit. Mus.; **PARDOTIGRIS** [Felidae] (p. 1325), near *Leo* Oken, type *P.* **onca** (*Felis o.* L.) (p. 1325), including also *P.* **palustris** (Burm.) n. comb. (p. 1325); *"Drepanodon"* **cautleyi** ("species incerti generis") (p. 1331), India, Upper Pliocene, type in Brit. Mus.; **TELOSMILUS** [incertae sedis] (p. 1331), provisionally proposed, type *"Drepanodon" cautleyi* Kretzoi; *Pseudaelurus* ? **pontopersicus** [Felidae] (p. 1332), Persia, Pontian, type in Naturhist. Mus., Wien. Nimravinae, emended diagnosis; **POGONODONTINAE** (p. 1333), n. subf. of Nimravidae, including *Pogonodon* Cope and possibly *Archaelurus* Cope; **DINICTINAE** (p. 1334), n. subf. of Machairodontidae, including *Dinictis* Leidy and *Metadeiniktis* Kretzoi; **HOPLOPHONEINAE** (p. 1334), n. subf. of Machairodontidae, including *Hoplophoneus* Cope, *Eusmilus* Gervais, *Pareusmilus* Kretzoi, and *Ischyrosmilus* Merriam; **EPIMACHAIRODONTINAE** (p. 1335), n. subf. of Machairodontidae, including *Epimachairodus* Kretzoi and *Homotherium* Fabrini; Machairodontinae, emended diagnosis; **SMILODONTINAE** (p. 1336), n. subf. of Machairodontidae, including *Smilodon* Lund, *Amphimachairodus* Kretzoi, *Trucifelis* Leidy, *Smilodontopsis* Brown, *Dinobastis* Cope, and possibly *Protamphimachairodus* Kretzoi; **PSEUDAELURINAE** (p. 1338), n. subf. of Felidae, including *Pseudaelurus* Gervais, *Parapseudailurus* Kretzoi, and *Metailurus* Zdansky; **NEOFELINAE** (p. 1338), n. subf. of Felidae, including *Neofelis* Gray; Pantherinae emended to include *Puma* Jardine; Nimravidae and Machairodontidae, emended diagnoses; **AILUROMACHAIRODONTIDAE** (p. 1340), with subf. **AILUROMACHAIRODONTINAE** (p. 1336), including *Ailuromachairodus* Kretzoi; **MEGANTEREONTIDAE** (p. 1341), with subf. **MEGANTEREONTINAE** (p. 1337), including *Megantereon* Croizet & Jobert and *Drepanodon* Bronn; Felidae, emended diagnosis; **DINAILURICTIDAE** (p. 1341), provisionally proposed, with subf. **DINAILURICTINAE** (p. 1337), including *Dinailurictis* Helbing; **MACHAIRODONTOÏDA** (p. 1342), n. tribe, including Nimravidae, Machairodontidae, Megantereontidae, and Ailuromachairodontidae; **EUAILUROÏDA** (p. 1346), n. tribe, including Felidae. The oldest representatives of the Aeluroïdea can be regarded as small, arboreal Pseudocreodi with specialized dentition, with their nearest relatives in the Oxyaenidae and Hyaenodontidae. Certain changes in the classification of the Ferae are proposed. The Eucreodi of Matthew are united with the suborder Carnivora, which includes the superfamilies Arctoïdea, **MUSTELOÏDEA** (p. 1350) (with Mustelidae as type and only family), and "Herpessoidae" [Herpestoïdea ?]. The new suborder **PARACARNIVORA** (p. 1349) is erected to include the superfamilies Pseudocreodi and Aeluroïdea, with Felidae as the type. The suborder Creodonta is made to include the superfamilies Procreodi and Acreodi. **ARCTODONTINAE** (p. 1350) is proposed as a new name for Arctotheriinae, since *Arctotherium* Bravard is a synonym of *Arctodus* Leidy. The Aeluroïdea are considered to be of African origin, the oldest genus *Ailurictis* being widespread in that continent. A table is introduced to show the geological and geographical distribution of the genera of Aeluroïdea. The spread of groups to the various continents at different geological periods is briefly discussed.

15096. PING, CHI. On the skeleton of Felis tigris. *Contr. Biol. Lab. Sci. Soc. China* 2(1): 1-6. 5 fig. 1926.—This specimen was shot in Amoy, Fukien. Comparison is made with bones of cat, dog, and leopard.—*A. M. Boring.*

15097. SIMPSON, GEORGE GAYLORD. A new Paleocene uintathere and molar evolution in the Amblypoda. *Amer. Mus. Novitates* 387. 1-9. 9 fig. 1929.—**PROBATHYOPSIS** (p. 1), type *P.* **praecursor*** (p. 2) from the Clark Fork of Wyoming, closely related to *Prodinoceras*. The problem of the molar pattern of uintatheres and coryphodonts is considered. It is concluded that *Probathyopsis* may be ancestral to the uintatheres, but is at most very distantly related to *Pantolambda*, and that the uintatheres cannot have been derived from *Pantolambda*.—*A. E. Wood.*

15098. SIMPSON, GEORGE GAYLORD. Additions to the Pleistocene of Florida. *Amer. Mus. Novitates* 406. 1-14. 7 fig. 1930.—Pleistocene mammals have been discovered in Florida in several localities: a fauna from the Itchatucknee River, associated with artifacts, including *Ondatra zibethica, Castor canadensis*, Lutra canadensis*, and *Mylohyus ?pennsylvanicus**; at Bradenton the mammoth, *Parelephas floridanus*, a skull of a capybara, *Neochoerus pinckneyi**, and the horn cores and occiput of *Bison latifrons**; in Sarasota Co. fossils from beach deposits, Pleistocene river clays, and typical stream and bog deposits.—*E. H. Colbert.*

15099. SIMPSON, GEORGE GAYLORD. American Mesozoic Mammalia. *Mem. Peabody Mus. Yale Univ.* 3(1): 1-171. 32 pl., 62 fig. 1929.—This monograph covers all known kinds and specimens of American Mesozoic Mammalia, treating the taxonomy, morphology, phylogeny, and geographic and geologic distribution of the Triconodonta, Symmetrodonta, Pantotheria, and the Mesozoic Multituberculata, Marsupialia, and Insectivora. Multituberculata, Plagiaulacidae: *?Psalodon* **marshi*** (p. 27), type in U. S. Nation. Mus. Symmetrodonta, incertae sedis: **EURYLAMBDA** (p. 41), type *E.* **aequicrurius*** (*Amphidon ae.* Simpson) (p. 41). Pantotheria, Paurodontidae: *Archaeotrigon* **distagmus*** (p. 52). Pantotheria, Dryolestidae: *Laolestes* **grandis*** (p. 64); *?Herpetairus* **humilis** (p. 74); *Melanodon* **goodrichi*** (p. 76). Pantotheria: **DOCODONTIDAE** (p. 84), type *Docodon* Marsh; this name replaces Dicrocynodontidae, since *Dicrocynodon* Marsh and *Ennacodon* Marsh are reduced to synonymy with *Docodon; Docodon* **superus*** (p. 95).

Types of new spp., except the first, in Peabody Mus., Yale Univ. All from the Morrison formation, Jurassic, Wyoming.—*H. E. Wood, II.*

15100. **SODY, H. J. V. Over Rattus rattus roquei Sody, met beschrijving van een nieuw ras van Rattus rattus van Soemba. [On R. r. roquei Sody with description of a new race of R. rattus from Soemba.]** *Zool. Mededeel.* [*Leiden*] 13(1/2): 94-99. 1930.—*Rattus r. roquei*, the tree rat of Java, is distinct from *R. r. jalorensis* of Malacca; *R. r. sumbae* ♀ (p. 98), East Soemba, type in Zool. Mus. Buitenzorg.

15102. **WEIDENREICH, FRANZ. Über die systematische Stellung des Australopithecus africanus Dart.** *Natur. u. Mus.* [*Frankfurt a/M*] 61(5): 229-234. 6 fig. 1931.—By comparing the relative proportions of the cranium and the facial part of the skull in *Australopithecus**, the author concludes that it is nearer to the Hominidae than are the chimpanzee* and the gorilla*, although it may still be considerably below the *Pithecanthropus* stage.

15103. **ANONYMOUS. Wild game census in Colville National Forest, northwestern Washington.** *Murrelet* 12(1): 26. 1931.—Census of game, predatory, and fur-bearing animals.

GENERAL

15105. GEITLER, LOTHAR. Über die Bedeutung der Grösse für die Organisation der Zelle. *Naturwiss.* 18 (14) : 301-305. 5 fig. 1930.—Body size is not the result of mere chance but is intimately connected with the life processes, since these are determined by the forces of molecular adsorption which are largely dependent on organelle size and, in particular, on the relation of volume to surface area. Evidence for this contention is adduced (1) from the absence of a nucleus in true bacteria (probably) and in the Cyanophyceae which seems to be correlated with the smallness of these cells. (2) In the algae in general, the smaller the cell the simpler the type of chromatophores. (3) Among Diatoms reduction in cell size is not merely geometrical but results in a different form since it takes place chiefly at the expense of the long axis, the others remaining almost constant. Such changes affect the developmental cycle because they influence sexual reproduction, there being a definite "copulation-size" among the organisms. Those that cannot conjugate die off. (4) The impossibility of organelles below a certain size for a certain type of organization is shown by comparing 2 vars. of *Cocconeis placentula.* A chromatophore of the *lineata* type is impossible in *pseudolineata* because the cells of the former are twice the size of the latter. (5) The different numbers of gametes formed by different diatoms is explained by cell size. Thus, large-celled sp. of *Navicula minima* regularly form 2 gametes whereas small-celled sp. form only 1. In general 2 gametes are formed by a small cell only when the nucleus, chromatophores, pyrenoids, etc., are realizable in sufficiently reduced form to fit into the cell. Hence size as a purely physical factor has an essential rôle in the differentiating of the cell and the changes of form of an organism.—*P. H. Yancey.*

15106. GREEN, WYMAN REED. The general status of sex and the sexes in organisms. *Jour. Tennessee Acad. Sci.* 2 (2) : 18-23. 1927.—Sex is a phenomenon not of individuals but of race, being related to the smallest racial unit, the "macrobion," which includes the neuters as well as the sexes. The locus of the primordial sex differentiation, not its quality, determines whether the sp. is bisexual or unisexual, etc. The clue to the guiding principle underlying the evolution of the sexes is to be found in the study of ontogeny. Sex is no more susceptible of evolution than is hunger or energy requirements. Secondary or even primary sex characters are in no sense expressions of sex. Life histories are cycles following the physico-chemical requirements of the law of successive reactions. Sex is related to the whole cycle in the same way as are the need for locomotion, for energy, or for means of defense.—*W. R. Green.*

15107. HÖBER, RUDOLF. Das Lebendige als Objekt naturwissenschaftlicher Forschung. [The living organism as object of scientific research.] 19p. Lipsius & Tischer: Kiel, 1930. Pr. 1 M.

15108. KINGSLEY, NATHAN H., and EDWARD J. MENGE. Laboratory studies, demonstrations, and problems in biology. 208p. Bruce Publishing Co.: Milwaukee, [1931?] Pr. $1.28.—This is a laboratory outline for an elementary course in high school biology, including 95 laboratory exercises in elementary botany, zoology, and physiology, with a short appendix on collecting and directions for a group of 16 projects.—*C. A. Kofoid.*

15109. LANTZ, C. W. The status of the biological sciences in the high schools of Iowa. *Proc. Iowa Acad. Sci.* 37: 101-105. 1930 (1931).—Biology has mostly replaced botany and zoology, and General Science has become almost universal. Training of teachers is inadequate. Biology is taught as related to human life.—*H. S. Conard.*

15110. LEPESCHKIN, W. W. My opinion about protoplasm. Sammelreferat. *Protoplasma* 9 (2) : 269-297. 1930.—Protoplasm is defined as a complex mixture of chemical substances. There are no living molecules, no living substances, but only living matter, i.e., a living mixture of chemical substances. The presence of a membrane on the surface of protoplasm is not necessary to explain its osmotic properties. The surface of protoplasm, which is not covered by a pellicula, is liquid. The colloidal structure of protoplasm is the only one possible. Pfeffer's hypothesis of a peculiar surface layer of protoplasm governing its osmotic properties is wrong; these properties are to be attributed to the whole mass. The dispersion medium of the colloidal system of protoplasm is a mixture of the principal compounds of protoplasm in water.—*W. Seifriz.*

15111. LEVI, GIUSEPPE. Organismo e tessuti. [Organism and tissues.] [Also in French.] *Scientia [Bologna]* 48 (219-7) : 19-32, and suppl. 7-19. 1930.—Organization, development, regeneration, hypertrophy, atrophy, abnormal activities including the formation of neoplasms, and the behavior of tissues in vitro are discussed from the standpoint of regulation by the organism; and it is concluded that there is the most profound difference between the life of the organism and the life of the tissues.—*M. M. Metcalf.*

15112. LOTKA, ALFRED J. The structure of a growing population. *Human Biol.* 3 (4) : 459-493. 1931.—A population growing according to the logistic law has a characteristic structure as regards age and sex composition, annual birthrate and deathrate, "inherent" as compared with the actual rate of natural increase, and other biometric functions. These characteristic features are developed by mathematical analysis in which a "generalized logistic" function, built up of the hyperbolic tangent and its derivatives, plays a leading rôle. The

discussion is first conducted for the special case of a population with a constant life table, then for the more realistic case of a population with a fluent life table, i.e., with gradually improving mortality conditions. In the case of a constant life table the curve of total annual births is very nearly a simple logistic, whose point of inflection comes about 35 yrs. before the point of inflection of the population growth curve. This is on the basis of the 1919-20 U. S. A. life table, and 35 yrs. in the mean age of the living in the corresponding "life table population." The curve of the birthrate per head is very nearly an inverted logistic, with its point of inflection about 22 yrs. later than that of the curve of total annual births, and about 12 yrs. before the point of inflection of the curve of population growth. The computed birthrates follow a course very similar to the observed. It is here clearly seen that a declining birthrate such as observed among the population of the U. S. A. is a necessary accompaniment of the logistic law of growth. A comparison of the age distribution in the logistic population with (1) a population growing according to the law of Malthus, and (2) the actual U. S. A. native white ♀ population brings out the fact that a population growing by the logistic law has a relative excess of persons at the reproductive ages, and that the actual structure of the U. S. A. native white ♀ population conformed quite closely to the computed logistic age distribution. The analysis further shows that the "inherent" or "true" rate of natural increase in a logistic population is necessarily always less than the "crude" or "observed."—*A. J. Lotka.*

15113. LYON, SCOTT C. Possibilities for the establishment of a biological station at Reelfoot Lake [Tennessee]. *Jour. Tennessee Acad. Sci.* 1(1): 11-15. 1926.

15114. McDOWALL, S. A. Biology and mankind. 224p. 46 fig. Macmillan Co.: New York, 1931. Pr. $2.50.—This is a statement of the course in general biology, given as the concluding year's work in a 5 yr. science course for classical students. The previous yrs. are given to physical geography, mechanics, chemistry, and physics. It therefore has a somewhat greater maturity of thought than the usual introductory course. Its aim is to present the significance of the biological basis of human life and its relations to problems of social and racial movements. It begins with a presentation of organic evolution and contrasts the Lamarckian and Darwinian hypotheses. The evidence for the inheritance of acquired characters is fairly summarized and rejected, with an examination of its social implications. The review of cellular basis of heredity and principles of Mendelian inheritance is followed by a discussion of its mechanism, of sex determination, and of the effects of inbreeding and outbreeding. The evidence of the extent and characteristics of Mendelian inheritance in man is reviewed and applied to social problems of population and human defects. National and international problems arising from outbreeding and inbreeding are discussed with reference to Ireland, Great Britain, and the U. S. A. and to the eugenic aspects of racial hybridization in general.—*C. A. Kofoid.*

15115. MENGE, EDWARD J. v. K. Biological problems and opinions. *Quart. Rev. Biol.* 5(3): 348-359. 1930.—Results of a questionnaire sent to the outstanding biological workers in all lands show the most important problems which need this generation's attention to be: the nature of life; the constitution of protoplasm; the mechanism of evolution; cancer research; the relation of genetics and environment; disease; criminality; racial superiority and inferiority; and problems of economic entomology.—*A. C. Haase.*

15116. METCALF, MAYNARD M. The place of research in the undergraduate college. A symposium by members of the Joint Committee on Research in Colleges. *Assoc. Amer. Colleges Bull.* 16: 1-7. 1930.

15117. PYCRAFT, W. P., editor. The standard natural history: From amoeba to man. 942p. 12 col. pl., 900 illus. Frederick Warne Co., Ltd.: New York, 1931. Pr., $6.00.—The purpose of the editor and his colleagues is to provide a balanced presentation of the entire animal kingdom such as to afford an easy, comprehensive survey of the classification of animals. The aim is to furnish a concise classification, and also to trace progressive development and to indicate existing and phylogenetic relationships. Adaptation of the animal to its environment is emphasized. A comprehensive account of the development of species, in all major groups, is included. Preceding a more detailed treatment of a given group there is a general discussion of the phylum, class, or order under consideration. The book is divided into sections in which the groups, ranging in rank from phylum to orders, are treated by the following authorities [the phylogenetic sequence observed in the book is sometimes broken in order to bring together all groups treated by one author]. M. BURTON: Protozoa (p. 5-20), Porifera (p. 21-28), Coelenterata (p. 29-40), Polyzoa (p. 68-71), Protochordata (p. 407-416); C. C. A. MONRO: Vermes (p. 41-67), Echinoderma (p. 77-101); in the group Vermes are included the phyla Annelida, Gephyrea, Rotifera, Gastrotricha, Nemertinea, Platyhelminthes, Nemathelminthes, Acanthocephala, Chaetognatha; G. C. ROBSON: Brachiopoda (pp. 72-76), Mollusca (pp. 102-147); W. T. CALMAN: Trilobita (p. 153), Crustacea (pp. 154-188); N. D. RILEY: Prototracheata (pp. 189-191), Insecta [exclusive of the Coleoptera and Diptera] (pp. 194-290), Hymenoptera (pp. 320-345); G. J. ARROW: Coleoptera (pp. 291-319); F. W. EDWARDS: Diptera (pp. 345-378); THEODORE H. SAVORY: Myriapoda (pp. 191-193), Arachnida (pp. 379-406); J. R. NORMAN: Salachii and Pisces (pp. 417-488) (a genealogical tree is given of fishes, p. 423); H. W. PARKER: Amphibia (pp. 489-510), Reptilia (pp. 511-563); W. P. PYCRAFT: Aves (pp. 564-779) with a phylogenetic tree showing the 6 main groups of "Neognathine" birds, and relative position of the "Palaeognathae" or ostrich-tribe; J. G. DOLLMAN: Mammalia (pp. 780-918). A comprehensive index concludes the book.

15118. SMART, HAROLD R. The logic of science. 234p. D. Appleton & Co.: New York, 1931. Pr. $2.50.—The chapters which are concerned with biological matters are II, On the general presuppositions, methods, and aims of natural knowledge, and VI, The biological sciences. The classificatory judgment, as it functions in the biological sciences, differs essentially from that in the mathematical and physical sciences. The relationship to which it gives expression is that of the individual to the class. The element of individuality becomes much more prominent than in the case of physical laws. In the latter case each particular counts only as another instance of the universal; in the former, we have the recognition of variability and adaptiveness, signs and indications of considerable inner diversity of structure and function, even amongst the members of the same species. And an explanation, in this realm, means the tracing of an evolutionary process of change, and possibly reference to purpose. The chapter on the biological sciences considers briefly the respective merits of mechanism, vitalism, and teleology, as methodological presuppositions for the guidance of the study of living things. It argues for Bergson's thesis that in the biological sciences the conception of natural kinds dominates the search for laws, somewhat as physical conceptions condition the application of mathematical principles to physical phenomena; and lastly it emphasizes the necessity of forming a clear idea of the process of evolution and of its natural limitation to the domain of living, quasi-individual entities.—*C. A. Kofoid.*

15119. THOMSON, J. ARTHUR, and PATRICK GEDDES. Life: outlines of general biology. 2 vols. 1515. Frontispiece. 202 fig. Harper & Bro.: New York & London, 1931. Pr. $15.00.—This treatise has a natural history background and a physiological framework with an evolutionary pattern. It is thus dynamic throughout. The treatment of the structural and systematic aspects is subordinated to the developmental and evolutionary. The material utilized is selected with reference to the

illustration of process or theory rather than to present an encyclopedic inclusive account. Its underlying philosophy is an attempt to interrelate the long standing and often contrasted mechanistic and vitalistic points of view. The general plan presents a summary of all important advances in the realm, mainly of animal biology, and with special reference to human interests. The introduction maps out the domain of biology and characterizes living creatures. The natural history, interrelationships, or ecology of organisms follows. Then follows an account of the functioning of the individual, especially as influenced by the hormones. A special chapter is devoted to the complex of problems associated with reproduction and sex from germ cells to parentage. The biopsychological patterns of organisms from rational thinking to the tropisms of the Protista are discussed, somewhat from the organismal point of view. Structure and classification are brought into the picture only to serve as foils for the discussion of generalities, such as symmetry, differentiation, integration, homology, analogy, convergence, change of function, vestigial organs, classification of tissues, the cell theory, and the species questions. The development of organisms, both plant and animal, affords opportunity for tracing the origin and continuity of germ cells, recapitulation, organisers, life histories, the curve of life, alternation of generations, the meaning of larval stages, longevity, the biology of death, and the play period and industries of animals. Organic evolution summarizes the ascent of both plant and animal life, notes the great steps in structural advance, the origin of organisms, the apartness of the bacteria, origin of insects and birds, effects of recurrent ice-ages, and the question of life beyond our world limits. The theories of evolution are followed from the earlier vague adumbrations to the latest aspects of holism. One finds here a very clear presentation of the oft-recurrent question of the inheritance of acquired characters, a loyal adherence to the main theses of the Darwinian hypothesis, and a summary of the factors of evolution. The biological factors which underlie human sociology, such as sex, individuality, woman's status in early stages of the evolution of human culture, the influence of the hunting stage and the cultivation of plants, and the present changing status of the sexes, are reviewed. The chapter on the wider aspects of biology touches upon such themes as the cultural value of natural history, biology and health, population, biology and ethics, war, eugenics, genius, education, biology and sociology, and relativity. This is followed by a chapter entitled "Toward a theory of life," naturalistic in basis, with a discussion of the origins of evils and of determinism or freedom. Four appendices treat respectively of (1) the great events in biology, a brief summary of the work of eminent biologists; (2) naturalists at work, largely an account of British enterprises; (3) how a biological outlook on life can be developed by education, containing an outline and discussion of educational methods; and (4) a guide to biological reading, with a very full classified list of nearly 1,000 titles.—*C. A. Kofoid.*

15120. WALKER, ERNEST P. Wild life protection—an urgent problem. *Ann. Rept. Smithsonian Inst.* **1930**: 327-346. 4 pl., 13 fig. 1931.—There is need for increasing the supply of wild life for recreational uses and for commercialization. The supply can be increased by proper administration or wild-animal husbandry on lands and water now producing scanty or no crops. Proper administration necessitates work by competent naturalists to ascertain existing conditions, to plan steps for improving conditions, to submit their findings and plans to those in a position to facilitate their execution, and to educate the public on the subject to the end of obtaining its full cooperation in improved wild-life production. Among various examples presented, it is shown that by limiting the open season for fur-bearers to the period when the fur is prime, the value of a smaller catch during this period may be greater than that of a larger catch during a more extended period.—*From author's summary.*

15121. WOLFF, MAX. Vom Missbrauch des Gesetzes der Kausalität in der Biologie. *Zool. Anzeiger* **86** (7/8): 175-179. 1930.—A plea is made for a clear distinction between mere opinion or expression of faith and scientifically established facts. Many zoologists, among whom are Konow, Haeckel, Forel, and Ostwald, have carried over religious or philosophical ideas into science to the detriment of the latter. The position of Kant and Schopenhauer on this matter is sound. The attitude of Volkmann, who avoids the question of causality in natural phenomena because it is too frequently confused with purpose and design, is especially commended. Teleological viewpoints may have a place in human thinking but not in science.—*A. M. Chickering.*

15122. WOOD, HORACE ELMER, 2nd. Priority in family, order and higher group names. *Science* **72** (1861): 219-220. 1930.—General agreement would be desirable on the method of applying priority to family names. The use of homonyms such as Cyclostomata (Bryozoa), Decapoda (Mollusca), and Tardigrada (Arthropoda) should be discontinued.—*H. E. Wood.*

15123. ZIMMERMANN, WALTER. Kritische Bemerkungen zu einigen biologischen Problemen. II. Zweckmässige Eigenschaften und Phylogenie. [Adaptations and phylogeny in some biological problems.] *Biol. Zentralbl.* **48** (4): 203-229. 1928.

PLANT

15124. FAIRCHILD, DAVID. Exploring for plants. 591p. 190 illus. Macmillan Co.: New York, 1930. Price $5.00.—A semi-popular narrative (based on notes taken during the Allison Vincent Armour expeditions for the U. S. A. Dept. of Agric., 1925, 1926, and 1927) of the author's experiences in studying, collecting, and introducing foreign plants and seeds into the U. S. A. and other parts of America. Descriptions of thousands of plants introduced have been recorded in the printed "Inventories of plant material introduced by the Office of Foreign Plant Introduction," and constitute the formal report of the expedition's activities. These explorations covered a wide range of territory extending from Panama, southern and Western Europe, the Mediterranean, northern and western Africa (a map facing p. 522 shows regions here visited), to southern Asia, including lesser known islands of the East Indies as well as Sumatra, Java, and Borneo (a map facing page 523 indicates regions here visited). Among results of these expeditions many new plants which give promise of economic or aesthetic value have already become established in America, among which may be mentioned: Mangosteen trees in Honduras; coconut and African oil palms in Panama; rock-cover plants in the parks of Seattle, Washington; poplars on the prairies of the Dakotas; Moroccan apricots in California; forage shrubs in the mountains of Arizona; shade trees, timber bamboos, sand dune shrubs, flowering vines, and strand trees and palms on the coast of Florida.

15125. HAUMAN, LUCIEN. Un voyage au pays des Araucaria. [A trip to the country of the Araucaria.] *Nouveau Jardin Pittoresque. Bull. Assoc. Nat. Belge.* **1927**: 205-210. Illus. 1927.—A botanical trip from Buenos Aires to the Argentine Cordillera in the territory of the Neuquen is described.

15126. MARTENS, P. Notes de botanique microscopique. 3e éd. 81p. Uystpruyst: Louvain, 1931. Pr. 12 fr.—A collection of practical notes for the guidance of first yr. students in the laboratory, including description and explanation of 74 preparations. The chapters treat of: the microscope; the cell; the nucleus and cell division; meristems; histology (differentiation of parenchymatous, supporting, conducting, secretory and protective tissues, epidermis and stomata); anatomy of the phanerogams (stem, leaf, root, primary and secondary structures); reproductive organs of phanerogams; vegetative and reproductive apparatus of pteridophytes, bryophyte and thallophytes.—*P. Martens (transl. by R. E. Cleland)*

15127. ROBBINS, WILFRED W. The botany of crop plants. 3rd ed. rev. 639p. 269 fig. P. Blakiston's Son & Co., Inc.: Philadelphia, 1931. Pr. $4.—This edition incorporates additions to our knowledge of crop plants since the publication of the 2nd ed. in 1924. Practically all chapters have been revised, several new illustrations added, and reference lists enlarged. Tables and matter pertaining to the distribution and yield of crop plants have been largely eliminated, so that this edition is more strictly botanical than the other two.—*C. S. Gager.*

ANIMAL

15128. CEDERSTROM, J. A. Retention of information gained in courses in college zoology. *Pedagogical Seminary & Jour. Genetic Psychol.* 38(1/4): 516-520. 1930.

15129. CHIDESTER, F. E. Zoölogy. A textbook for college and university students. 581p. 268 fig. D. Van Nostrand Co., Inc.: New York, 1932. Pr. $3.75.—This book is divided into 22 chapters, the titles of which indicate its predominantly taxonomic character as compared with the "principles" type of text-book. The Introduction deals with generalities and definitions of plants and animals, the subdivisions of zoology, cellular and chemical constitution, physiology and relationships of animals and a scheme of classification in the order of Mammalia to Protozoa. Then follows a chapter each for the phyla Protozoa, Porifera, Coelenterata, Platyhelminthes, Nemathelminthes, Annelida, Trochelminthes, Molluscoidea, Echinodermata, Mollusca, Arthropoda and Chordata, which are treated unequally according to the author's idea of their importance. This brings the text to p. 221. In addition to the more strictly taxonomic and morphological matter reference is generally made to geographical distribution, paleontology, ecological relations, economic importance and frequently to other subjects of popular interest concerning each group. Several groups, such as Sipunculoidea and Echiurida, are omitted altogether, though the latter is named in error for the Echinoidea in the introductory table. Treatment of the Chordata is expanded in chapters on the classes Cyclostomata, Pisces, Amphibia, Reptilia, Aves, Natural History of Mammals and Physiology of Mammals, the latter being especially comprehensive. There is a short chapter on the Social Life of Animals and a final one on Evolution, Heredity and Eugenics. The volume is designed to appeal not only to the general culture college student but to students specializing in zoology, in premedical sciences, and in agriculture, which explains the emphasis placed on certain aspects of the subject. Several distinctive features are worthy of note. The illustrations are abundant and fresh. A large part of them either were drawn especially for this book or were taken from sources not previously drawn upon for text-book illustrations. Many of the chapters were read and shaped in the making by specialists and brief statements of several special theories and points-of-view were written by their authors, thus giving an added authority. There is much information on topics not usually mentioned in text-books of general zoology. This usually appears in the form of short paragraphs introduced by a catchword printed in italics or heavy-faced type.—*J. P. Moore.*

15130. GASTHUYS, P. Historique de la protection de la faune au Congo Belge. *Bull. Agric. Congo Belge* 21(2): 374-379. 1930.—This is a chronologic résumé of the game laws of the Belgian Congo, dealing principally with the protection of the larger animals such as the elephant, the white rhinoceros, and other animals sought for their rarity by collectors and hunters. The location of park preserves for animal protection is described. One of the weaknesses of the game laws is the ordinance declaring that the amateur hunter when killing in defense of his life, or that of others, or of his property, may appropriate the ivory of the animals thus killed under the sole condition of registering.—*M. Buchsbaum.*

15131. REED, H. D., and B. P. YOUNG. Laboratory studies in zoology. 121p. 4 fig. McGraw-Hill Book Co.: New York, 1930. Pr. $1.00.—The object of this book is to meet the principal difficulties encountered by beginners and to provide an outline sufficiently elastic to meet preferences of the individual instructors. One-third of the book is based upon the frog as a type to illustrate zoological method, animal organization, and biological principles. Brief sections on mitosis, development, and heredity follow. The last half is given to a discussion of the principal phyla of animals and closes with a key to phyla and classes.—*J. P. Moore.*

15132. SCHMIDT, JOHANNES. Oceanographical expedition of the Dana, 1928-1930. *Nature [London]* 127(3203): 444-446. Map, 2 fig.; (3204): 487-490. Map, 2 fig. 1931.—This globe-circling expedition made investigations in many of the principal enclosed seas as well as the 3 oceans. Its main features were: making very large collections of pelagic life in the different depths of the various oceans; obtaining data on the physical and chemical composition of the different water layers; and subjecting a number of important pelagic forms, represented by abundant individuals, to finer analysis by biometrical methods. There is a special discussion of the striking latitudinal distribution of the recently described eel genus, *Nessorhamphus.* Each of the 2 known sp. occurs in the Indian, Pacific, and Atlantic Oceans, *N. ingolfianus** about the transitional circles, and *N. danae** (p. 487) in the equatorial belt. In a supplement (pp. 489-490), HELGE THOMSEN discusses "Oxygen in the tropical Pacific." From Panama to Tahiti an O minimum (of generally less than 5%) occurs at about 400-500 m., the amount steadily increasing as lower depths are reached. From Tahiti to New Caledonia the minimum does not go below 40%, this being reached at about 2000-2500 m. Probably this layer especially poor in O is centered about lat. 5-10° N. and extends right across the whole Pacific. This O minimum has about the same geographical distribution as the equatorial counter current, and the poor O layer under the latter shows that in these depths the currents with a meridional component must be extremely weak.

15133. STILES, C. W. Is an international zoological nomenclature practicable? *Science* 73(1892): 349-354. 1931.—The author gives a historical review of the International Rules on Nomenclature and of various attempts which have been made to alter them more or less radically. Special mention is made of propositions from Berlin and Vienna, and of the Horn Resolution adopted at Padua. American zoologists are urged to define their position towards this resolution.—*C. W. Stiles.*

15134. STRAND, EMBRIK. Nomenklatur und Ethik. Zurückweisung nomenklatorischer Entgleisungen der Herren Dr. Th. Mortensen und Prof. Dr. R. Richter. *Folia Zool. et Hydrobiol. [Riga]* 2(1): 25-46. 1930.—A controversial article answering Mortensen and Richter, and defending his own nomenclatorial practices.

15135. THORPE, W. H. Biological races in insects and their significance in evolution. *Ann. Appl. Biol.* 18(3): 406-414. 1931.—A biological race is a sub-specific group of individuals separated from other members of the same morphological sp. by definite and constant biological differences; structural and pigmentary differences are either completely absent or else very slight and inconstant. Biological races are usually distinguished by food preferences and seasonal distribution. Thus, whereas, a geographical ssp. is characterized by differences of average size or pigmentation and is isolated by geographical barriers, a biological race is characterized primarily by biological characters and is isolated by biological differences such as food and mating preferences. Biological races are known to exist in most of the main invertebrate groups. They appear to be most highly developed in the Insecta, Arachnida, and Nemathelminthes. There is also evidence of their existence in Coelenterata, Porifera, and Protozoa. In the 2 latter groups, where morphological characters are often slight and unreliable, the concept of a sp. fades insensibly into that of a biological race. This, of course, does not imply that the morphological characters of a sp., even in the higher

groups, are any more fundamental or important than the biological; they are accentuated merely for the sake of convenience in systematic work. With regard to insects, the host plant preferences which provide the basis for most biological races may be either germinally fixed or may be merely "memory reactions." The latter are renewed in each generation owing to the preference of an adult insect for oviposition on the particular food plant on which it was nourished as a larva,—the so-called "host selection principle." In the case of those which are germinally fixed, the probability that such biological characters may be of survival value is obvious. But even where the characters are of no direct value or where they are not germinally fixed, they may well be of evolutionary importance in that they would provide physiological barriers—lines of cleavage in an otherwise homogeneous population, which aid the spread and establishment of any new variety which might arise. In a number of cases, true biological races appear to have been induced experimentally. In most of these a Lamarckian explanation has been suggested. As regards insects there does not seem to be any one instance in which all other theories are completely ruled out, but there are 1 or 2 cases concerning plant-feeding Nematodes which make a Lamarckian explanation much more difficult to dispense with. Taken as a whole the phenomenon of biological races seems to provide a considerable amount of circumstantial evidence for some form of Lamarckian theory.—*W. H. Thorpe.*

APPARATUS AND TECHNIQUE

15137. **BRADBURY, O. C. A new dehydrating agent for histological technique.** *Science* 74 (1913): 225. 1931.—In experiments with animal tissues isopropyl alcohol not only is as good a dehydrating agent as ethyl alcohol, but causes less hardening of tissues. Tests with plant material are suggested.

15138. **FRIESNER, RAY C. A microtome knife cooler.** *Butler Univ. Bot. Studies* 1 (paper 12): 176. 1 fig. 1930.

15139. **GRAUPNER, HEINZ, und ARNOLD WEISSBERGER. Über die Verwendung des Dioxans beim Einbetten mikroskopischer Objekte. Mitteilungen zur mikroskopischen Technik I.** *Zool. Anzeiger* 96 (7/8): 204-206. 1931.—Dioxan (diethylene-dioxide) is miscible with water and with methyl and ethyl alcohol in all proportions, and also with paraffin at 60°. It may be kept dry by the addition of KCl. Methods of using it as a paraffin solvent for imbedding are given.

15140. **GROVE, A. J. An apparatus for keeping marine organisms under circulation in narrow observational tanks.** *Jour. Marine Biol. Assoc. Unit. Kingdom* 16 (3): 757-760. 1 pl. 1930.—This modification of Cannon & Grove's (1927) apparatus is made by holding a U-shaped rubber tube between 2 glass plates with spring clips.

15141. **GUILD, STACY R. Accumulation of gas in closed collodion sacs immersed in flowing tap water.** *Science* 70 (1812): 287-289. 1928.—Collodion sacs, 16 mm. in diam. and about 60 mm. long, filled with water or with aqueous solutions of various salts or gases and firmly closed without inclusion of free gas bubbles, when placed in slowing flowing tap water, became completely filled with gas in 6-7 days. In one measured experiment a pressure sufficient to support a 49½ in. water column in a 5 mm. glass tube was developed. The gas bubbles disappeared from the sac when it was taken out of tap water and put into a solution which had been "degassed" by means of a faucet filter pump. The information derived from these experiments is applicable in histological technic when there is distortion of tissues due to retained gas, as for example, in the membranous labyrinth.—*S. E. Johnson.*

15142. **HARVEY, E. NEWTON, and ALFRED L. LOOMIS. A microscope-centrifuge.** *Science* 72 (1854): 42-44. 2 fig. 1930.—The apparatus described enables one to get a magnified image of cells making 2,000-3,000 revolutions per min. at 10 cm. from the centrifugal axis. The cells are mounted on a slide clamped to the centrifuge arm. The source of light is fixed above the slide. Light passed through the slide into an ordinary microscope objective is then diverted by totally reflecting prisms to the eyepiece fixed above the centrifuge axis. By lighting cells for a few micro seconds every time they reach a certain point in revolution, they appear stationary and their contents show effects of centrifugal force. A special Hg lamp is described.—*M. B. Garnett.*

15143. **HOLMES, W. C., and A. R. PETERSON. The atmospheric dealkylation of aqueous solutions of cresyl blue.** *Stain Technol.* 6 (3): 79-82. 1931.—Aqueous solutions of cresyl blue are decidedly less stable than those of methylene blue. An appreciable degree of dealkylation occurs even under only slightly alkaline conditions (e.g., pH 7.68) and at room temp. within a few weeks. At pH 9 the dye is distinctly affected within 24 hrs.—*Authors (courtesy Wistar Bibl. Serv.).*

15144. **JOHNSON, B. K. Sources of illumination for ultra-violet microscopy.** *Proc. Phys. Soc. [London]* 43 (2): 127-137. 2 pl., 4 fig. 1931.—The conclusions recorded in the literature that a spark discharge between Cd electrodes is the most suitable source of illumination are confirmed. The brightness of the spark was found to be a function of the energy input and of the capacity employed. The frequency of alternation seems to have little effect.—*W. Marquette.*

15145. **LEECHMAN, DOUGLAS. Technical methods in the preservation of anthropological museum specimens.** *Bull. Canada Dept. Mines* 67. 127-158. 1931.—Methods of combating insect pests in museums are discussed and preservation of the following materials is considered: antler, babiche, baleen, bone, buckskin, feathers, fur, hair, horn, ivory, leather, rawhide, shell, sinew, turtleshell, wool; basketry, birchbark, resin, textiles, wood (including totem-poles); amber, beads, clay, copper, glass, gold, iron, lead, pictographs, pottery, silver, stone. There is a short bibliography.—*D. Leechman.*

15146. **PORTER, ALFRED W. The formation of images and the resolving power of microscopes.** *Jour. Roy. Microscop. Soc.* 49: 245-251. 1929.—A comparison is made of Abbe's and Rayleigh's methods of applying the diffraction theory in explaining the formation of images in the microscope. The importance of secondary spectra in calculating the resolving power is stressed, but it would be a mistake to consider this of great importance in practice.—*W. G. Marquette.*

15147. **SAVAGE, ALFRED, and M. C. JAMIESON. Note on the combined use of photo-electric cell and projection microscope.** *Canadian Jour. Res.* 3 (4): 322-326. 1 fig. 1930.—A method is described whereby the comparative areas of irregularly shaped microscopic objects may be rapidly determined. It consists of staining them with fuchsine and projecting their magnified images into a photo-electric cell insensitive to red light. The photo-electric current is inversely proportional to the sizes of the images and, at low magnifications, may be measured with a sensitive galvanometer.—*Authors' abstract.*

15148. **SCHMIDT, W. J. Dichroitische Färbung tierischer und pflanzlicher Gewebe.** In: **EMIL ABDERHALDEN. Handbuch der biologischen Arbeitsmethoden.** Abt. V. **Methoden zum Studium der Funktionen der einzelnen Organe des tierischen Organismus.** Teil 2. Heft 16. Lief. 355. 1835-1924. 1 col. pl., 24 fig. Urban u. Schwarzenberg: Berlin, 1931.—The writer discusses the property of some dyes and elements, such as metals and iodine, of showing one color in transmitted light and another in reflected light (dichroism). He goes into detail concerning certain theories to explain dichroism. Thus according to Ambronn dichroic staining is brought about by dyes being deposited in small particles which are oriented in one direction. Ambronn's theory is no longer held in all details, but it is believed that the phenomenon appears because the particles of the sub-

stance stained have a certain definite orientation. The phenomenon is not bound to color, as the color of the object can be changed without destroying the dichroicity. Thus it has been found that cellulose fibers, stained *dichroically with congo* red, continue to show the dichroic property even after treating with lead acetate which intensifies the red color. Objects which are doubly refractive stain dichroically; e.g., cellulose of plants, almost all animal fibers, and under certain conditions cell plasma, chromatin and chondriosomes. For staining, physical maceration has ordinarily been employed, but sections of material fixed in alcohol or $HgCl_2$ are also satisfactory. Fox showed that cellulose fibers are dichroic regardless as to whether the dyes are acid, basic, or those used in dyeing cotton. If mordants are used—tannin for basic dyes and alum or soda for acid dyes—the dichroicity is less pronounced; but if the resultant lake is dissolved the property will reappear. Some consideration is given to the application of the principle to histology. Nearly all the material given is drawn from the literature, although the author is apparently familiar with the technic.—*H. J. Conn and L. M. Hansen.*

BIBLIOGRAPHY AND HISTORY

15152. BRETSCHNEIDER, ARTHUR. Die höhere Bundeslehranstalt und Bundesversuchsstation für Wein-, Obst- und Gartenbau in Klosterneuburg. [The institute for horticultural teaching and research at Klosterneuburg.] *Ernähr. Pflanze* 27(19): 410-414. 11 fig. 1931.

15153. FRACASTORIUS, HIERONYMUS. De contagione, et contagiosis morbis et eorum curatione. Libri III. Translation and notes by WILMER CAVE WRIGHT. 356p. G. P. Putnam's Sons: New York, 1930. Pr., $4.50.

15154. GUNDER, J. D. North American institutions featuring Lepidoptera. XVIII. The museums of Cuba. *Ent. News* 41(9): 290-295. 3 pl. 1930.—The Museo de Historia Natural of Havana, under the direction of Mario Sanchez Roig, has a large collection of Lepidoptera. At Havana is also the Museo "Valle Yznaga," under the Inst. of Havana (director, Serafin Espinosa), and containing the Gundlach collection. The Museo Municipal Emilio Bacardi Moran at Santiago is under the direction of Jose Bofill and his son. At this city also lives Ozario Querci and his family, well known commercial collectors of Lepidoptera.

15155. GUNDER, J. D. North American institutions featuring Lepidoptera. XIX. Entomological institutions in Mexico. *Ent. News* 41(10): 313-318. 5 pl. 1930.—The oldest of the Mexican lepidopterists is Robert Müller, Mexico City, the owner of the largest collection of Mexican butterflies and moths. Other private collectors are his nephew, Max Draudt, and Pablo Petersen of Puebla. The other collections of note are official. The Mexican Plant Protection Service of the Ministry of Agric. is under the direction of Alfonso Dampf, concerning whom biographical data are given. Among his assistants are Leopold Conradt and Ignacio H. Olmedo. The medical entomological work is conducted by the Dept. of Public Health in Mexico City under the direction of C. C. Hoffman, who has a private collection of Lepidoptera. The Biological Inst. of the Mexican National Univ. is under the direction of Isaac Ochoterena who heads the National Museum of Nat. Hist.

15156. HYDE, H. A. The Welsh National Herbarium. *North Western Nat.* 6(3): 135-139. 1931.—History and brief summary of contents.

15157. MALIKOFF, GABRIELLE E., Editor. Union list of serials in libraries of the United States and Canada. Suppl. 1925-1931. 660p. H. W. Wilson Co.: New York, 1931.—Contains new titles and titles previously listed in main volume. Entries represent either corrections or holdings of new libraries or of libraries that have acquired or completed sets since original volume was published. Many cross references which tend to be useful in locating a title in the list have been added. [For abstract of original list see B. A. 2(6/8): entry 8641.]

15158. MONTESSUS de BALLORE, R. de, ed. Index generalis 1932. Annuaire général des universités. (French and English editions.) Éditions Spes: Paris. U. S. Agents: W. H. Allen: Philadelphia; Williams & Wilkins Co.: Baltimore. Pr., 225 fr. 1932.

15159. PEROTTI, R. I Laboratori di Patologia e Batteriologia del R. Istituto Superiore Agrario di Pisa e l'annesso R. Osservatorio Regionale di Fitopatologia. [The pathological and bacteriological laboratories of the Royal Agric. Inst. of Pisa and its annexed regional survey of phytopathology.] 18p. 12 fig. Stabilimento Editoriale Vallerini: Pisa, 1929.—History and description.

15160. POLEVOY, P., and B. PENTEGOFF. Research institutions of the Russian Far East. *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 1: 313-314. 1926(1928).

15161. ROYS, RALPH L. The ethno-botany of the Maya. *Tulane Univ. Middle Amer. Res. Ser., Pub.* 2: 1-359. 1931. Pr., $5.00.—Knowledge of plants from which food, clothing and shelter were obtained was part of the heritage of every Maya Indian farmer in Middle America 20 centuries ago; but study of medicinal plants and their properties was a specialized science confined to a priestly class which, since the Spanish conquest, survives as the "yerbateros." Plant-medicine suffered least of any of ancient Maya culture from European invasion. A considerable body of native Maya literature on the subject exists in MS. form, in the European script adapted to the special needs of the language of Yucatán by early missionaries. Indications are that the MSS. were compiled from much older sources. This volume offers a survey of the botanical knowledge of the Mayas, essentially an agricultural people who turned to the forest to supplement their food supplies in times of scarcity. Medicine was closely associated with religion and sorcery. Maya doctors believed in curing like with like. Yet a surprisingly large percentage of Maya medical texts were devoted to treatment of symptoms and are based on objective observations of effects of certain plants on the human system. Even when the Maya doctor borrowed from the Spaniards, he usually adhered

to his own methods and adopted their simple remedies rather than their pseudo-scientific theories. Maya medicine at least was not hampered by the theories of humors and distempers which so long continued to be the basis of European medical science. Maya methods of human sacrifice must have resulted from a practical knowledge of anatomy among the priests and doctors, probably handed down from generation to generation. The yerbatero's services are still in demand. Suggestion plays an important part in the cure. Little is known as to the extent to which this system of medicine has spread outside the Maya area. Most of the book's 359 pages contains only the plant-medicine remedy in Maya with an accompanying translation into English. There is also a vocabulary of Maya terms relating to the growth, parts and environment of plants, an annotated list of Maya plant-names, a table of nomenclature, an annotated list of Maya fauna names, a chapter on the climate and food-supply of Yucatán, a bibliography and an index.—*M. Ries.*

15162. **WOOD, CASEY A., (compiled and edited by). An introduction to the literature of vertebrate zoology, based chiefly on the titles in the Blacker Library of Zoology, the Emma Shearer Wood Library of Ornithology, the Bibliotheca Osleriana [The Gest Library of Chinese Literature], and other Libraries of McGill University, Montreal, Canada.** 643p. Col. frontispiece. Oxford University Press: London: Macmillan: New York, 1931. Pr., $15.—This attractively made quarto opens with a beautifully colored frontispiece depicting a Dodo from an original drawing in the Blacker Library. Following a preface the book consists of 3 parts: an introduction to the literature of vertebrate zoology p. 1-146, an author index p. 147-174, and catalogue of titles of vertebrate zoology in the libraries of McGill University p. 175-643. The preface gives much historical and other information relating to the indexed libraries. The introduction is divided into 19 short chapters and is essentially a history of the literature of vertebrate zoology with particular emphasis placed on ornithology and including bits of information and lively comments by the editor. Beginning with Aristotle the first 3 chapters carry the account into the 17th Century. Modern vertebrate zoology is dealt with by topics. Chap. IV and VI deal with systematics and evolution and V with records of explorations. Other chapter headings are animal painters and illustrators, faunas and bionomics (2 chap.), important works on ornithology and mammalogy (3 chap.), zoogeography and ecology, important treatises of ichthyology, herpetology and amphibiology, oriental literature, periodicals, and unique and rare printed books. The index is a list of authors arranged geographically, chronologically and by taxonomic classes with a single word indicating the scope of the work. The body of the book is the catalogue of titles arranged alphabetically by authors, editors or title of series with full bibliographical references and numerous descriptive annotations and comments, which are especially full on birds.—*J. P. Moore.*

15163. **ANONYMOUS. Facilities for advanced study and research in agricultural science and cognate pure sciences in the United Kingdom.** 141p. Ministry of Agric. & Fisheries: London, 1929.—Includes soils and crops, horticulture, animal pathology, animal husbandry, and other economic phases of agriculture.

(See also in this issue Entries 15105, 15110, 15137, 15139, 15142, 15180, 15181, 15185, 15186, 15188, 15189, 15190, 15191, 15196, 15199, 15204, 15208, 15214, 15215, 15227, 15228, 15240, 15241, 15249, 15259, 15283, 15284, 15285, 15286, 15287, 15290, 15423, 15427, 15621, 15649, 15656, 15751, 15755, 16303, 16309, 17030, 17102, 17298, 17348, 17349, 17355, 17360, 17381, 17385, 17386, 17395, 17471, 17476, 17481, 17488, 17500)

GENERAL

15164. **SAX, KARL. The mechanism of crossing-over.** *Science* 74(1906) : 41-42. 1931.—A reply to criticisms by Darlington, of the author's paper: Chromosome structure and the mechanism of crossing over.

PLANT

15165. **BOWEN, ROBERT H. The distribution of the plastidome during mitosis in plerome cells of Ricinus.** *Cellule* 39(1) : 123-154. 3 pl. 1929.—The proplastids are rod-shaped and aggregate about the poles of the mitotic spindle assuming a radiate arrangement. Individual proplastids are not seen to divide during nor immediately before mitosis but those present are distributed in approximately equal numbers to the two daughter cells. The literature on the subject of plastid distribution is discussed. Cytoplasmic arrangement is believed to determine the orientation of the mitotic spindle in both plants and animals without regard to the presence or absence of centrosomes.—*A. M. Showalter.*

15166. **COLLINS, J. L., and KENNETH R. KERNS. Genetic studies of the pineapple (Ananas sativus Lindl.) I. A preliminary report upon the chromosome number and meiosis in seven pineapple varieties and in Bromelia pinguin L.** *Jour. Heredity* 22(5) : 139-142. 2 fig. 1931.—The haploid number in 7 varieties is 25. Root tip nuclei showed 50 chromosomes. Meiosis appeared to be regular but differences in size of pollen grains were observed. Six triploid plants with 75 chromosomes were found in a hybrid population of about 8000 plants produced by crossing a wild type from Brazil with the Cayenne. Heilborn had previously reported a 75 chromosome pineapple from Ecuador. The chromosomes are small and rounded in both pollen mother cells and root-tip cells. *Bromelia pinguin,* a species closely related to the pineapple, had 48 chromosomes in haploid cells. Morphologically they are similar to those in *Ananas.*—*J. L. Collins.*

15167. **DEMBOWSKI, JOHANN. Karyologische Studien an Wurzelmeristemen höherer Pflanzen. I. Die Persistenz des Nukleolus bei der Zellteilung in Wurzelmeristemen von Helianthus annuus. 2. Die Anlage der jungen Zellwand in meristematischen Zonen von Helianthus und Monstera.** *Bot. Arch.* 28(1/2) : 1-56. 26 fig. 1929.—I. The nucleolus contains no chromatin. During mitosis it consists of 2 or possibly 3 substances which differ in form and color. In nucleolar division, the contents break up into spheres which are later freed into the nuclear cavity. At anaphase these bodies pass to the poles with the chromosomes and are there reassembled as the telophase nucleoli. In *Monstera* as well as *Helianthus,* substances diffuse from the daughter nuclei to the equator, forming dark, transverse zones. These substances are thought to act as ferments, building up the new cell wall out of raw materials derived from the remains of the mother nucleus, with cytoplasmic additions.—*M. M. Lesley.*

15168. **EMERSON, STERLING H. The reduction division in a haploid Oenothera.** *Cellule* 39(2) : 159-165. 1 pl. 1929.—Heterotypic prophase figures in a haploid *O. franciscana* showed as many parallel threads as are found in corresponding diploids, leading to the interpretation that these parallel threads in diploids do not represent a pairing of homologous chromosomes. Two chromosomes often were attached at one end. It is suggested that these may be two chromosomes of the ring of four

in the parent. The distribution of chromosomes was not random, the most frequent class being 6:1.—*S. H. Emerson.*

15169. **ERLANSON, EILEEN WHITEHEAD.** A group of tetraploid roses in central Oregon. *Bot. Gaz.* 91(1): 55-64. 3 fig. 1931.—Cytological material from *Rosa durandii, R. myriadenia,* and *R. yainacensis* showed that these are balanced tetraploids with 14 pairs at diakinesis. A semisterile *R. nutkana* was hexaploid. These tetraploid roses resemble *R. nutkana* in the size of flowers and hips, and in inflorescence type. In the number of stamens, fine serrations of the leaflets, size of pollen grains, and amount of sterile pollen they resemble the tetraploid *R. californica.* This tetraploid group seems to have a limited range, perhaps from central Oregon to the northern counties of California. It may have originated from a crossing between *R. nutkana* and *R. californica.* Some other rose species of limited range in this area may belong to this group. They are *R. delitescens, R. brownii, R. calavera, R. pinetorum,* and the forms in northern California usually classified as *R. muriculata.* Pollen grain size might be used in distinguishing the tetraploid and hexaploid rose forms in herbaria. The cubes of the mean length of the pollen of diploid, tetraploid, and hexaploid are as 1:1.7:1.9.—*Author's summary.*

15170. **HEIMLICH, L. F.** Microsporogenesis in Cucumis sativus. *Cellule* 39(1): 1-24. 3 pl. 1929.—The primary sporogenous cells function directly as spore mother cells. Their nuclei are small and contain little chromatin, which composes a very fine reticulum. The reticulum transforms into slender threads that conjugate parasynaptically and contract, forming a confused mass about the prominent nucleole. After synizesis the spireme is thicker and shows evidence of pairing of chromomeres. Mitochondria are prominent in a zone surrounding the nucleus during the two divisions. The nucleole diminishes in size and ultimately disappears, sometimes after marked changes of form. Occasionally a portion of nucleole is found associated with the chromosomes and difficult to distinguish from them. An intranuclear multipolar spindle is formed and changes to a bipolar one. Cytokinesis is by furrowing of the plasma membrane. Occasionally one or more spores of a tetrad disintegrate. The reduced number of chromosomes is 7.—*A. M. Showalter.*

15171. **LENOIR, M.** Étude vitale des cellules mères du pollen chez Lilium candidum L. *Compt. Rend. Soc. Biol.* 106(10): 813-814. 1931.—A method of removing the pollen mother cells from the anther is described. After removal, cytoplasmic streaming can be observed; the cells can be plasmolysed at this time also. The nucleoli function normally. Hence removal from the anther does not destroy vital properties.—*E. Weiner.*

15172. **MANGENOT, GEORGES,** (preface by A. GUILLERMOND). Données morphologiques sur la matière vivante. 258p. 54 fig. R. Guillon: Paris, 1930. Price 31.50 fr.—A review, dealing with the nature of protoplasm in plant cells, designed primarily for persons with scientific background but without cytological training. The subject-matter is treated under 6 chief headings: a general discussion of protoplasm and the products of its activity; the cytoplasm; the chondriosomes; the nucleus; the paraplasm; the cell and cellular differentiation. While the general outline of the book follows a strictly morphological pattern, the subject is treated from a broadly physico-chemical point of view, a considerable proportion of the book being devoted to the chemistry, physics and physiology of the various cellular structures. Thus, the chapters on the cytoplasm, chondriosomes and nucleus each include sub-headings dealing respectively with the morphology, chemistry and functions of these portions of the cell. The chapter on the paraplasm treats in a similar manner of the vacuome, of various inclusions, of skeletal structures, as well as of various other substances elaborated by the cytoplasm or by the chondriosomes. A subject index is included, but there is neither an author-index, nor a bibliography; and, although various workers are mentioned in the text, no specific references to individual papers or books are given.—*R. E. Cleland.*

15173. **ROBYNS, WALTER.** La figure achromatique, sur matériel frais, dans les divisions somatiques des Phanérogames. *Cellule* 39(1): 85-119. 1 pl. 1929.—The polar caps are formed of nucleolymph outside the nuclear membrane and increase in size as this membrane contracts. Both the caps and the ultimate spindle are optically homogeneous with no semblance of fibers or plates. The fibers and plates of fixed material are asserted to be entirely artifact, as are also dermatosomes. The cell plate is first discernible as a continuous membrane and becomes the middle lamella.—*A. M. Showalter.*

15174. **SOUZA VIOLANTE, J. M. de.** La parasyndèse dans Balsamina hortensis et Campanula persicifolia. *Cellule* 39(2): 235-266. 4 pl. 1929.—Prochromosomes are prominent in somatic nuclei of meristems of Balsamina and are of diploid. In early prophase nuclei of sporocytes, the prochromosomes are associated in pairs ("zygosomes") which are haploid in number. No true leptotene is found. Parasynapsis is demonstrable in the earliest stages of prophase. In *Campanula* no prochromosomes are discernible but the behavior is otherwise similar.—*A. M. Showalter.*

15175. **THOMPSON, W. P.** Chromosome homologies in wheat, rye and Aegilops. *Canadian Jour. Res.* 4(6): 624-634. 1931.—A review.

15176. **TURESSON, GÖTE.** Studien über Festuca ovina L. II. Chromosomenzahl und Viviparie. *Hereditas* 13(2/3): 177-184. 2 fig. 1930.—Three different sexual types of *F. ovina* were found to have 7 haploid chromosomes. Three apomictic or amphi-apomictic, viviparous types had the following chromosome complements: 1. *rogalandica,* a dwarf form from western Norway is triploid with somatic chromosome number 21. 2. In *svolvaeriensis,* a more vigorous type with larger bulbs, 2n=28. 3. In *tennforsiensis,* a very high and vigorous form, 2n=42. It is completely apomictic. There is an increasing sexual sterility with increasing chromosome number. The types with higher chromosome numbers may have arisen through hybridization, through the production of diploid gametes in some plants or by somatic duplication. The increasing degree of viviparity with increasing chromosome number indicates that they may have arisen from diploid gametes in forms with lower chromosome number and a slight degree of viviparity.—*H. Wexelsen.*

15177. **VOKES, MARGARET MARTIN.** Nuclear division and development of sterigmata in Coprinus atramentarius. *Bot. Gaz.* 91(2): 194-204. 48 fig. 1931.—After fusion of the 2 nuclei in the basidial cell, synapsis takes place in the single nucleus. This nucleus then migrates to the apex of the cell and its membrane comes in contact with the cell wall, where four hyaline bodies become attached. With the withdrawal of the nucleus to the center of the cell cytoplasmic threads are drawn out. These connect the hyaline bodies left on the wall to the nucleus. The centrosomes of the spindles are not interfered with in the formation of the four hyaline bodies which remain on the basidial wall. After the first division, threads from four hyaline bodies are attached to the two nuclei; after the second division, threads from four hyaline bodies are attached to as many nuclei. The long axis of the spindle has no definite orientation in either division. The hyaline bodies remain attached to the apex of the cell wall from the time the fusion nucleus comes in contact with it until after formation of the spores. These bodies react on both the wall and the nucleus in such a way that the wall pushes up at their points of contact and sterigmata form. The nucleus then follows, and after it has entered the spore the wall greatly enlarges and assumes mature proportions. After the hyaline bodies become attached they remain at all times at the apex. After a sterigma forms, a hyaline body is at the tip, as well as after the spore is formed. There are 8 chromosomes in the fusion nucleus. Reduction takes place in the first division. —*Author's summary.*

ANIMAL

15178. GRABOWSKA, Z. Über die Plasmakomponenten (Golgi-Apparat u. a.) in den männlichen Geschlechtszellen von Potamobius astacus L. [In Polish, with German summary.] *Bull. Internat. Acad. Polonaise Sci. et Lett. Cl. Sci. Math. et Nat. Sér. B: Sci. Nat. (II)* [*Zool.*] 1929(3/6): 197-214. 1929.—The behavior of the mitochondria, Golgi material and vacuomes in the development of these non-flagellated spermatozoa was studied in vivo, in material stained intra vitam, and in fixed material. The vacuome is identical with the internum of the Golgi material, and is characterized by affinity for neutral red. The Golgi material stains black with osmic acid in the absence of chrome salts. These changes in staining properties are attributed to secretory activities in the formation of the motor organ or (and) centrosomal apparatus. The mitochondria are characterized by affinity for dahlia and gentian violet and the usual stains. They do not coalesce, but remain granular, gather at the poles in the spermatid, and, except for a minute remnant, are sloughed off.—*R. C. Whitman.*

GENERAL

15179. ACQUA, CAMILLO. Ambiente ed eredità dei caratteri acquisiti. (A proposito del 2° Congresso Italiano di genetica.) *Ann. Tecnica Agraria* 3(2): 127-138. (Latin abstract p. 283-284.) 1930.—The author summarizes the position of Enriques at the Congress of Genetics, in which he stated that of the 3 kinds of environmental influence, "homotypic induction" does not exist; "heterotypic induction," if it exists, fails to explain evolution; while "collective induction" furnishes an explanation of adaptation. Unusual environmental conditions acting on germ plasm as well as soma may effect hereditary changes.—*H. D. Hill.*

15180. HALDANE, J. B. S. Theoretical genetics of autopolyploids. *Jour. Genetics* 22(3): 359-372. 1930.—The gametic series to be expected from various types of heterozygous autopolyploids (polyploids in which a chromosome is equally likely to pair with any of two or more others) are given, and the effects of self-fertilization and random mating on populations are considered.—*R. J. Garber.*

15181. WETTSTEIN, FRITZ von. Über plasmatische Vererbung und über das Zusammenwirken von Genen und Plasma. *Ber. Deutsch. Bot. Ges. 1. Generalversammlungsheft* 46: (32)-(49). 1928.

15182. WETTSTEIN, R. Das Problem der Evolution und die moderne Vererbungslehre. *Zeitschr. Indukt. Abstamm.- u. Vererbungsl. Suppl.* 1: 370-380. 1928.

PLANT

15183. ANDERSON, EDGAR, and DOROTHEA de WINTON. The genetic analysis of an unusual relationship between self-sterility and self-fertility in Nicotiana. *Ann. Missouri Bot. Garden* 18(1): 97-115. 1 pl. 7 fig. 1931.—An anomalous plant of *Nicotiana alata* was female cross-sterile with *N. langsdorffii* and with a self-fertile garden hybrid. When used as a pollen parent it produced F_1's each of which was composed of self-fertile and self-sterile plants in approximately equal numbers. The self-sterile F_1's were female cross-sterile with their self-fertile parent *N. langsdorffii,* and female cross-fertile with self-sterile plants of *N. alata.* These anomalies are interpreted as due to a single factor, S_F, belonging to the allelomorphic *S* series studied by East. S_F behaves like the self-sterility allelomorphs previously described except that it has the additional property of retarding the growth of pollen tubes carrying the S_f (full fertility) allelomorph as well as those carrying S_F. The hypothesis was tested by F_2 and back cross families and fully confirmed. The effect of gametic elimination caused by interaction of the *S* factors should be morphologically apparent in species crosses. Such an effect is demonstrated in this material.—*E. Anderson.*

15184. BARTOSCH, JULIUS. Untersuchungen über die Vererbung der Knollengestalt bei der Kartoffel. (Untersuchungen zur Genetik der Kartoffel. III. Herausg. von K. O. MÜLLER.) *Arb. Biol. Reichsanstalt Land- u. Forstwirtsch.* 18(2): 117-131. 1930.—Tuber shape is expressed in a coefficient of length: breadth. The material was analyzed with the aid of statistical constants. Progenies of selfed seed of the parents, F_1 progenies and F_2 progenies of certain F_1 individuals, were studied. Tuber shape and formation of secondary tubers were shown to be heritable characters by positive correlation between parents and progeny. Correlation between tuber shape and formation of secondary tubers was not established. The monohybrid inheritance of tuber form advanced by previous authors did not fit the material. The results are explained by the multiple-factor hypothesis, involving 3 or 4 factor pairs which somewhat influence the thickness of the tuber.—*F. A. Krantz.*

15185. BAUR, ERWIN. Mutations-Auslösung bei Antirrhinum majus. *Zeitschr. Bot.* 23 (Festschr. Oltmann's): 676-702. 19 fig. 1930.—The completely homozygous strain of snap-dragon used showed a mutation rate of 1.5% under ordinary circumstances. This rate is based only on easily perceived mutations. Plants 6 to 8 weeks old (i.e., with only diploid cells) were subjected to experimental conditions. Some had the stem tips merely immersed in various solutions, others had the tips immersed in tubes of solution and were whirled about in centrifuge. 216 treated plants flowered and set seed. They were normal-looking. Progeny (F_1) tests showed that only two of the 216 had become heterozygous for easily observed mutant characteristics,—a frequency essentially the same as untreated material. A further generation (F_2) from inbreeding F_1 was grown. 1936 F_2 groups revealed in 23 of them new recessive characters—a mutation rate about like that for "spontaneous" changes. Neither the kind nor the strength of the stimuli had any relation to the mutants found. However, this research yielded an unexpectedly high number of "non-factorial mutations" whose basis is cytoplasmic, whose transmission is through the ♀, and whose expression vegetatively is variable.—*J. P. Kelly.*

15186. BEADLE, GEORGE W. Heritable characters in maize XXXIII. Slit-leaf blade. *Jour. Heredity* 21 (1): 45-48. 3 fig. 1930.—This recessive factor (*sb*) is characterized by a decrease in size and ultimate disappearance of the plastids in certain longitudinal regions between the main vascular bundles of the leaf. Nuclear disintegration follows, and the tissues made up of the dead cells are often mechanically torn. The *sb* gene lies in the *Y-Pl* chromosome, some distance to the left of *Y.* The order of the genes is *sb-Y-Pl.*—*Author's summary.*

15187. BERG, v. Züchtung des Sagnitzer Roggens 1930/31. *Zeitschr. Zücht. Reihe A, Pflanzenzücht.* 16 (4): 657-661. 1931.—Selection methods are described used with ordinary rye varieties and with those ryes showing tendencies toward developing self-pollinating strains.—*L. R. Waldron.*

15188. BLEIER, H. Genetik und Cytologie teilweise

und ganz steriler Getreidebastarde. *Bibiographia Genetica* 4: 321-400. Martinus Nijhoff: The Hague, 1928.—A comprehensive survey of the many researches on hybridization in cereals, covering hybrids obtained with einkorn, with numerous emmer-spelt combinations, and with wheat-rye, *Aegilops*-wheat, *Aegilops*-rye, *Aegilops*-wheat-rye, and *Triticum villosum* parentage. Data are given regarding chromosome numbers, fertility and sterility, genetics, and the question of the origin and relationships of the various types of cereals.—*A. B. Stout.*

15189. **BUCHHOLTZ, J. T., and A. F. BLAKESLEE.** Radium experiments with Datura I. The identification and transmission of lethals of pollen-tube growth in F_1's from radium-treated parents. *Jour. Heredity* 21 (3): 119-129. 15 fig. 1930.—Three genetic abnormalities obtained following radium treatment were manifested after pollination: (1) failure of half of the pollen grains to germinate; (2) early bursting of half the pollen tubes, lethal to the male gametes affected; (3) slower growth of half the pollen tubes, a semi-lethal condition in that under normal conditions growth is too slow to permit the pollen tube to reach the ovary. Recessive genes rather than chromosomal abnormalities are probably responsible for these effects.—*L. M. Dickerson.*

15190. **CLAUSEN, J.** Cytogenetic and taxonomic investigations on Melanium violets. *Hereditas* 15(3): 219-308. 150 fig. 1931.—This paper reviews the author's cytological and genetic studies on this group. The cytology of species hybrids, the taxonomic and genetic relationships of the Melanium spp., the species concept, and the origin of the new spp. are discussed. In all, 25 successful specific crosses are reported. *V. tricolor* and *V. arvensis* occupy a central position in the section since they cross with a large number of the spp.; *V. cornuta* crosses only with *V. orphanidis* and *V. elegantula; V. calcarata* only with *V. battandieri.* In the collective species *V. kitaibeliana,* morphologically similar types are very incompatible, while one of the forms, *nana,* is compatible with the morphologically different type *V. tricolor.* In meiosis of the pollen mother cells the F_1 hybrids show a variable amount of chromosome conjugation with varying numbers of univalents, bivalents and polyvalent chromosome associations. There is no complete parallelism between morphological similarity and chromosome conjugation. The fertility of the F_1 varies considerably, a very irregular meiosis is often combined with a fairly good fertility. Autosyndesis occurs in some crosses. Taking the amount of chromosome conjugation as an indication of chromosome homology, many difficulties arise, many spp. which after their behavior in some crosses would be expected to conjugate in F_1 fail to do so; a species may show autosyndesis in one cross and not in another. This must mean that homology of chromosomes tends to produce conjugation if not prevented by other factors, environmental or genetic. In some hybrids the lagging univalents that divide at the first anaphase lead to an increase of chromosome number in later generations; in other crosses the elimination of chromosomes leads to a decrease in number. Crossing favors segmental interchange between nonhomologous chromosomes in later generations, resulting in multivalent association of chromosomes into long chains. Specific differences are determined by Mendelian genes. A gene can be introduced from one sp. into another, irrespective of chromosome number. Segregations of genes for anthocyanin show that there is parallelism between the degree of chromosome polyploidy and polymery of these genes. *V. alpestris* and *V. arvensis* show rather close genetic relationship. New constant, fertile vigorous types have been isolated from these crosses, some of which have a chromosome number new in the section. These new spp. are just as characteristic as many of the wild ones and no doubt would have been regarded as "good" spp. if found in nature. The following types have been named: *V.* **phaeno-elegantula,** *V.* **crassicaulis,** *V.* **hyperchromatica,** *V.* **petaloidea** and *V.* **velutina.** The spp. of the Melanium section constitute a complete series of transitions as regards intersterility, morphological differences and chromosome conjugation in hybrids. No sharp line can be drawn between specific and subspecific differences. It becomes impossible therefore to give any definite criteria of specific differences and one must abstain from making a definition of the species concept. In classification, however, all available methods must be used. Such studies must include morphology, ecology, geographical distribution, chromosome morphology, crossing ability and chromosome behavior in hybrids.—*H. Wexelsen.*

15191. **CLAUSEN, ROY ELWOOD.** Inheritance in Nicotiana tabacum. XI. The fluted assemblage. *Amer. Naturalist* 65(699): 316-331. 1931.—The fluted assemblage comprises a series of derivatives obtained directly or indirectly from fluted, a type monosomic for the F-chromosome. Two of these, the recessive types coral and mammoth, are shown to be due to secondary modification of the F-chromosome. Coral and mammoth crossed with normal or with each other, exhibit frequent non-conjunction of the F-chromosomes, as a consequence of which the F_2 populations contain haplo-F and triplo-F types in addition to the expected classes of offspring. No crossing-over was observed between coral and mammoth. A type called pale sterile also appeared in some lines and was found to owe its sterility to extensive non-conjunction of the chromosomes in meiosis. From pale sterile $\times$ normal, variable offspring were produced consisting of monosomic, trisomic and other more complex chromosomal variants. Four instances of origin of carmine-coral variegation are reported; one of which was shown to be due to fragmentation of the F-chromosome and to be subject to reversion to a self-carmine condition. The evidence indicates that coral, and probably also mammoth, is not due to factor mutation; but to some special form of modification to which the F-chromosome is subject when in the univalent condition. —*R. E. Clausen.*

15192. **COLBY, A. S.** Some raspberry varieties being used as parents in breeding. *Proc. Amer. Soc. Hort. Sci.* 27: 422-424. 1930(1931).—In a preliminary study of over 6000 individuals, Quillen appears to be by far the most useful parent in breeding work at the Illinois Station, with a number of seedlings outstanding as to anthracnose resistance and excellence in fruiting characters. Gregg and Honey Sweet rank well. Seedlings of Cumberland, Plum Farmer, Older, Black Pearl, Earhart, and Munger do not, in general, appear as good as the parents. Some promising individuals resulted from the Honey Sweet-Plum Farmer cross. An occasional hybrid purple of Quillen-Latham parentage is outstanding.—*A. S. Colby.*

15193. **COOK, R. C.** Chimera or accident of development? *Jour. Heredity* 21(9): 386. 1 fig. 1930.—A flower cluster of *Daucus carota* having a sector of maroon flowers is figured and described.—*L. M. Dickerson.*

15194. **CORRENS, C.** Vererbungsversuche mit buntblättrigen Sippen. VIII. Nochmals Stellaria media status albomaculatus. IX. Hypericum perforatum status paralbomaculatus. X. Primula malacoides forma albomarginata. XI. Coleus hybridus forma (?) albopicta. *Sitzungsber. Preuss. Akad. Wiss. Phys.-Math. Kl.* 1931 (10/11): 203-231. 8 fig. 1931.—White and green variegation of *Stellaria media* (status *albomaculatus*) is inherited through ovules only as indicated by the data from crosses: variegated $\times$ green and $F_1 \times$ green. Non-Mendelian white and green variegation of *Hypericum perforatum* (status *paralbomaculatus*) is transmitted both through ovules and pollen as indicated by reciprocal fertilization of green by variegated branches, by self-pollinations and by reciprocal crosses with green plants. White margins on leaves of *Primula malacoides* (forma *albomarginata*) are inherited as a simple Mendelian recessive. Variegation in *Coleus hybridus* forma (?) *albopicta* is influenced by environment. It is, probably, inherited as a dominant Mendelian character.—*M. Demerec.*

15195. **DARROW, GEO. M.** Foliacious calyx of the young dewberry. *Jour. Heredity* 21(5): 216. 1 fig. 1930. —Dewberries showing a tendency to produce leaves in-

stead of sepals are figured. This is a genetic character, appearing only under the influence of undetermined environmental stimuli.—*L. M. Dickerson.*

15196. **DAVIS, BRADLEY MOORE. Some attempts to obtain haploids from Oenothera Lamarckiana.** *Amer. Naturalist* 65(698): 233-242. 1931.—Some 200 ovaries of *O. lamarckiana* from which the styles had been cut were pricked and slashed without inducing the parthenogenetic development of seeds. Pollinations of *lamarckiana* involving wide crosses likewise failed to induce the development of haploids. Tables give the results of these experiments.—*B. M. Davis.*

15197. **DICKERSON, L. M. The inheritance of ruby seed coat color in peas (Pisum sativum).** *Jour. Heredity* 22(10): 319-321. 1931.—Ruby, a seed coat color, is independent in inheritance from specking (*F*). Ruby is tentatively designated as *Ru*, its allelomorph as *ru*. *Ru* is dominant in F_1 during the immature stages of seed development, but segregates as a "recessive" in the mature seed coats of the F_2. Being visible in the immature seed coats and masked by the later appearance of gray, it gives the appearance of reversal of dominance. The masking of Ruby in mature *RUru* seeds by *Gc* may possibly be interpreted as epistasis of *Gc.—Author's summary.*

15198. **EDMOND, J. B. Seasonal variation in sex expression of certain cucumber varieties.** *Proc. Amer. Soc. Hort. Sci.* 27: 329-332. 1930(1931).—Plants of 5 commercial varieties grown in the greenhouse from June 27 to September 6, 1929; from December 15 to April 15, 1929-30, and from February 17 to May 25, 1930, varied in the staminate to pistillate ratio from 39.29:1 to 8.58 to 1; from 0.059:1 to 0.005:1 and from 0.345:1 to 0.012 to 1 respectively. Though varietal standings were not maintained during the three periods, the results show that high light intensity with long length of day is favorable for the production of a large number of staminate flowers, while low light intensity with short length of day is more favorable for the production of pistillate forms. During the long days of summer, plants were vigorous, possessed long internodes and large leaves; while during the short days of winter, plants were weakly vegetative, possessed short internodes and small leaves. —*J. B. Edmond.*

15199. **EMERSON, STERLING. The inheritance of rubricalyx bud color in crosses with Oenothera Lamarckiana.** *Proc. Nation. Acad. Sci. U. S.* 16(12): 796-800. 1930.—Three types of F_1 plants occur in crosses between *O. lamarckiana* and *O. rubricalyx: velans·^{h}latifrons* with a ring of 8 chromosomes and 3 pairs, in which bud color is independent of the *velans* lethal and the ring; *gaudens·^{h}latifrons* with the same configuration, in which bud color is completely linked to the *gaudens* lethal and the ring; and *gaudens*·modified-*velans* with a ring of 12 and a pair, in which bud color is linked to the *velans* and *gaudens* lethals and to the ring. The *velans* lethal and the gene for bud color are in different chromosomes but show complete linkage when both chromosomes are in a common ring.—*S. Emerson.*

15200. **EYSTER, W. H. Heritable characters of maize XLI—Dilute Aleurone.** *Jour. Heredity* 22(7): 225. 1 fig. 1931.—A dilute aleurone gene, *da*, greatly reduces the intensity of aleurone color in maize. It is inherited as a simple Mendelian recessive, and is the expression of a gene which has its locus in chromosome I, as indicated by its rather close linkage, with approximately 11% crossing over, with aurea chlorophyll deficiency.—*W. H. Eyster.*

15201. **EYSTER, W. H. Heritable characters of maize XLII—Reduced Endosperm.** *Jour. Heredity* 22(8): 250-252. 4 fig. 1931.—Two genetically different strains of maize with subnormal-sized kernels are illustrated and described as reduced endosperm$_1$ and reduced endosperm$_2$. These characters are inherited as simple Mendelian recessives and have their loci in chromosome VIII, at approximately 15 and 1 crossover units, respectively, from the locus of vivipary$_2$.—*W. H. Eyster.*

15202. **GOULDEN, C. H. Breeding rust resistant varieties of wheat. Fundamental aspects of the problem.** *Sci. Agric.* [*Ottawa*] 10(4): 258-267. 2 fig. 1929.—A review of the literature with 34 titles listed. The inheritance of mature plant resistance is independent of seedling resistance, very simple, and offers possibilities for production of resistant varieties.—*H. D. Hill.*

15203. **GRUBER, FRITZ. Über Selbststerilität und Selbstfertilität bei Antirrhinum.** 32p. 7 fig. Paul Dünnhaupt, Grossdruckerei: Köthen, Anhalt. 1930.—Self-pollinations and cross-pollinations were made within each of the 3 groups of self-sterile snapdragons, namely, Orgiva, Chorro, and Baryacas, containing 20-30 plants each. With the exception of one crossing combination, all plants in the Orgiva group were cross-fertile, indicating the presence of a large number of sterility allelomorphs. Within the Chorro group there were 4 crossing combinations and their respective reciprocal crosses which were sterile. In this group there is a larger number of intra-sterile and inter-fertile classes. Doubtful results were obtained from the 3d group, Baryacas, on account of a lack of flowers. One plant in the Orgiva group was entirely self-fertile, which is explained as being due to a mutation of a fertility factor. —*M. C. Gillis.*

15204. **HAASE-BESSELL, GERTRAUD. Über Genombindungen.** *Zeitschr. Indukt. Abstamm.- u. Vererbungsl. Suppl.* 1: 778-784. 1928.—The basic chromosome number (genom) in *Digitalis* is 12. In the polyploid *D. purpurea* (4 genoms, 2n=48), assumption of independent assortment and combination among the sets of homologous chromosomes explains the appearance of a dominant character in a recessive line (i.e., Rr rr=white; upon selfing, throws Rr Rr, red).

15205. **HARLAN, HARRY V. The origin of hooded barley.** *Jour. Heredity* 22(9): 264-272. 5 fig. 1931.—Hooded barley is assumed to have originated in Nepal as a mutation in the awn of a naked 6-rowed barley. At the time when first reported it had not spread to eastern China and Japan or to western Asia. A sterile hooded mutant was found at Aberdeen, Idaho, in a hybrid population. One of the parents was an awned, 6-rowed, naked sort from the same region in which the hooded form is assumed to have first occurred.—*H. V. Harlan.*

15206. **HARRINGTON, J. B. The relationship between endosperm development and morphologic characters in the F_2 generation of a T. dicoccum × T. vulgare cross.** *Canadian Jour. Res.* 5(2): 208-218. 1 pl. 1931.—The relationship between the degree of plumpness of F_2 seeds and the type of the resulting F_2 plants was studied in the cross Vernal (*T. dicoccum*) × Marquis (*T. vulgare*). A random sample of F_2 seeds was divided into three classes based upon kernel plumpness, viz. plump (Class A), slightly shrunken (Class B), and shrunken (Class C). In these there were by number 55.5, 41.0 and 3.5% of seeds respectively. Emergence of F_2 plants in the field was 64, 58 and 36% for Classes A, B and C. The F_2 plants were studied for 13 morphological characters. Comparing the populations for all characters combined, Class A was more *dicoccum*-like than Class B, and Class B much more *dicoccum*-like than Class C. The proportion of *vulgare*-like character was 16, 20 and 32% for Classes A, B and C, respectively. Considering the character of the individual plants, the ratios of *dicoccum*-like to *vulgare*-like were 12.1:1, 5.3:1, and 2.2:1 for classes A, B and C, respectively. Furthermore, the *vulgare*-like plants of classes A and B were less *vulgare*-like than those of Class C. There were present, however, in Classes A and B some plants that were fully as *vulgare*-like as any in Class C. These results indicate that, in an interspecific wheat cross, the breeder should give special attention to the shrunken F_2 seeds if he has very limited nursery space and a large amount of seed; whereas if he has plenty of space for a large population, special care of shrunken F_2 seeds does not seem warranted.—*Author's abstract.*

15207. **HARTMAN, HENRY. Hybrids between Pyrus malus and Pyrus fusca.** *Jour. Heredity* 20(8): 379-380.

3 fig. 1929.—Hybrids of *P. fusca,* the "Oregon Crab-apple," and *P. malus,* now found in the wild and occasionally in cultivation west of the Cascade Mountains in Oregon, Washington and British Columbia, are distinctive in many ways and constitute a fairly definite type. In F_1 the fruit combines the principal characteristics of both parents. It is high in acid and astringent compounds.—*Author's abstract.*

15208. **HERIBERT-NILSSON, N. Über das Entstehen eines ganz Cinerea-ähnlichen Typus aus dem Bastard Salix viminalis × caprea.** *Hereditas* 15(3): 309-319. 5 fig. 1931.—In the F_2 of the cross *S. viminalis* × *S. caprea,* a plant was found which in all important taxonomic characters resembled *S. cinerea.* It was sterile in crosses with both parent species. *S. cinerea* can only with difficulty be crossed with *viminalis* and *caprea.* The chromosome numbers are: *caprea* and *viminalis,* $n=19$; *cinerea,* $n=38$. The chromosome number of the *cinerea*-like plant was not definitely ascertained, but it was at least triploid. The case is regarded as an experimental synthesis of *S. cinerea,* and of the new type, *S.* **neocinerea.** It is probable that *S. cinerea* has arisen through a similar cross in nature. The hybrid *viminalis* × *caprea* is fertile and not rare in nature.—*H. Wexelsen.*

15209. **IMAI, YOSHITAKA. New mutant characters of the Japanese morning glory.** *Jour. Heredity* 22(11): 361-366. 7 fig. 1931.—Five new mutant characters, rootless, folded, lilliputian, cocoa and shrubby, are described. Aside from a deficit in the segregating ratio of some mutant forms, they are simple recessives.—*Y. Imai.*

15210. **JENKINS, MERLE T. Heritable characters of maize XXXIV—Rootless.** *Jour. Heredity* 21(2): 78-80. 1 fig. 1930.—This character (*rt*) affecting root development is inherited as a simple Mendelian recessive to normal.

15211. **KÄMMERLING, HANS. Über Geschlechterverteilung und Bastardierung von Ustilago longissima und ihrer Varietät macrospora.** *Zeitschr. Bot.* 22(3): 113-142. 2 maps. 1929.—*U. longissima* and its variety *macrospora* have been shown to have 3 sexual types, A, B, and C. *Longissima* A has been crossed with *macrospora,* both B and C. Tri-sexuality is explained by assuming multiple allelomorphs of the sex gene. Genetically distinct mycelia may infect a single plant and result in complications.—*H. D. Hill.*

15212. **KAKIZAKI, YOITI. Breeding "crossed egg plants" in Japan. An example of the practical utilization of hybrid vigor.** *Jour. Heredity* 21(6): 253-258. 4 fig. 1930.—Methods are described for practical utilization of heterosis. Important increases in yield were obtained in F_1 plants, particularly when the parent varieties differed widely in many characteristics. The pollinating technique described gave 80-90% of successful crosses.—*L. M. Dickerson.*

15213. **KARPER, R. E. The effect of a single gene upon development in the heterozygote in sorghum.** *Jour. Heredity* 21(4): 187-192. 1 fig. 1930.—A recessive lethal gene responsible for white seedlings and its effects upon the heterozygote were studied in kafir No. 223, a pure line inbred for 7 years. An albino mutation occurred in this presumably completely homozygous race. Height measurements of homozygous and heterozygous green plants at 20, 40, 60, 80, and 137 days showed no significant differences. Weight of plant, weight of head, and length of head of plants heterozygous for the albino gene and those homozygous for normal showed no statistically significant differences, although heterozygous plants were slightly heavier, with heads slightly longer, and produced a few more suckers and side branches than normal plants. When all other factors are held constant, this recessive chlorophyll gene does not have a deleterious effect on the heterozygote and the principal advantage gained in eliminating this gene from seed stock comes from getting rid of homozygous recessives, which impair the stand in the field.—*R. E. Karper.*

15214. **KEARNEY, THOMAS H. Genetics of cotton. A survey of our present knowledge.** *Jour. Heredity* 21(7): 325-336; (8): 375-384; (9): 409-415. 11 fig. 1930.—The morphology and mode of inheritance of 14 characters in the genus *Gossypium* are described and discussed; others are mentioned. The small number of examples of typical Mendelian inheritance is attributed to the widespread use of interspecies crosses by investigators. $n=13$ in the Asiatic cottons. Allelomorphic series have been reported for leaf form, petal spot and fuzzy seed. Linkage between a few factors has been reported, but in some cases the experimental evidence is not given. In the citations 49 titles on cotton are given.—*L. M. Dickerson.*

15215. **KUHN, E. Über Kreuzungen des getrenntgeschlechtigen Thalictrum fendleri mit gemischtgeschlechtigen Arten der gleichen Gattung.** *Biol. Zentralbl.* 50(2): 79-102. 10 fig. 1930.—The following crosses were made: Dioecious carpellate *Thalictrum fendleri* ($n=14$) as mother was crossed with monoecious *T. foetidum* ($n=7$), *T. delavayi* ($n=14$), and *T. aquilegifolium* ($n=7$). All of the F_1 hybrids were hermaphroditic with a decided development of maleness. In *T. fendleri* × *aquilegifolium* the carpels are reduced in number from 9-12 to 1, as the average, and these are thus almost pure staminate individuals. The anthers, carpels and ovules are externally normally developed, but after the development of the archesporium disturbances appear, sooner or later, in pollen and embryosac, which lead to a high degree of sterility. The tendency of the hybrids to develop maleness cannot come from the bisporangiate fathers but must come from the unisexual mother. Heterogamy of the female is not to be considered, since no females or female bisporangiate individuals arise, and a loss of female determining zygotes is improbable. As a working hypothesis, the author suggests homogamety for the female and a male-determining plasma. Seed development without pollination does not take place in *T. dasycarpum.* The *n* number of chromosomes for the species so far studied by the author are: *Thalictrum aquilegifolium* L., *petaloideum* L., *orientale* Boiss., *prezewalskii* Maxim., *tuberiferum* Maxim., *foetidum* L., *alpinum* L.=7; *lucidum* L., *glaucum* Desf., *dalavayi* Franch, *tuberosum* L., *fendleri* Engelm.=14; *minus* L.=21; *simplex* L. "I"=28; *simplex* L. "II"=35; *flavum* L.=42; *dasycarpum* Fisch. et Lall.=77; *polyganum* Muhl.=77 (?).—*J. H. Schaffner.*

15216. **LAIBACH, F. Die Bedeutung der homostylen Formen für die Frage nach der Vererbung der Heterostylie.** *Ber. Deutsch. Bot. Ges.* 47(9): 584-596. 4 fig. 1929.—Contrary to a bifactorial scheme advanced by Ernst to explain normal heterostyled and homostyled individuals in *Primula hortensis,* Laibach finds in *Linum austriacum* a complicated multiple factor situation. A homostyled plant of the latter species on selfing gave not homostyled but chiefly normal long-styled plants with great variation in relative length of filaments and styles. The diversities are considered to be conditioned by many multiple factors. The author's original homostyled plant was exceedingly heterozygous for genes controlling stamen and style lengths.—*J. P. Kelly.*

15217. **MacARTHUR, JOHN W. Linkage studies with the tomato. III. Fifteen factors in six groups.** *Trans. Roy. Canadian Inst.* 18(1): 1-19. 1931.—Fifteen pairs of inherited tomato characters are described and the monofactorial genetic basis of each shown. A lengthy statistical summary of all the dihybrid F_2 and backcross ratios observed to date by the author covers nearly all the possible combinations, taking 2 at a time. Deviations from the expected dihybrid ratios, stated in terms of standard errors, are used for detecting linkages. The 15 gene pairs definitely located are: 4 in group I, 1 in II, 2 in III, 2 in IV, 3 in V, and 3 (or 2?) in VI. Five or six others, unattached as yet but apparently independent of the 15, may represent markers in some or all of the 6 remaining "chromosomes."—*J. W. MacArthur.*

15218. **MALINOWSKI, EDMUND. Heterozja u fasoli. [Heterosis in Phaseolus vulgaris.]** [With English summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest Ann.)* 22: 183-188. 2 fig. 1929.—These experiments, conducted in zinc pots of special construction, have shown that some vigorous F_2 individuals breed true in subse-

quent generations. Some vigorous F_4 lines crossed with dwarf varieties of kidney bean transmitted the large size to the F_1.

15219. **MANGELSDORF, P. C., and R. G. REEVES.** **Hybridization of maize, Tripsacum, and Euchlaena.** *Jour. Heredity* 22(11): 328-343. 10 fig. 1931.—Pollen grains of *Tripsacum* germinate readily on the styles of *Zea* but fertilization ordinarily does not occur. By cutting off the styles of maize to less than an inch in length, true hybrids of these two distantly related genera were produced. There are many abnormalities in the development of the hybrid seeds and only about 4.54 seeds mature per 10,000 silks pollinated. Hybridization is facilitated to some extent by pollinating the ears with maize pollen 24 hours after pollinating with *Tripsacum*. Hybrid seeds in the vicinity of maize seeds develop better than hybrids growing alone. The somatic chromosome number of maize is 20, *T. dactyloides* (Texas) 36, and *T. dactyloides* (Connecticut) 72. Crossed seeds of maize × Texas *Tripsacum* had 38 chromosomes in the endosperm, 28 in the embryo and 28 in the root tips. Crosses of maize × Connecticut *Tripsacum* had 46 chromosomes in the root tips. The F_1 hybrids exhibit characteristics of both parents but resemble *Tripsacum*, the pollen parent, more closely than *Zea*, the seed parent. The F_1 plants are perennial, tiller profusely, and bear an inflorescence very similar to that of *Tripsacum*. Crosses of *Euchlaena* and *Tripsacum* were also made but no viable, mature seeds were obtained.—*P. C. Mangelsdorf.*

15220. **MASON, SILAS C.** **A sectorial mutation of a Deglet Noor date palm.** *Jour. Heredity* 21(4): 157-163. 5 fig. 1930.—A sectorial chimera which involves a lateral strip over 36% of the circumference of the stem is described. The mutation affects the trunk, foliage, inflorescence and fruit. It can be traced to the apical bud. The data indicate that the mutation may have arisen from a mutation in one of three apical cell initials.—*L. M. Dickerson.*

15221. **MATSUURA, HAJIME.** **Genic analysis in Avena, a monograph.** *Jour. Fac. Sci. Hokkaido Imp. Univ. Ser. 5. Bot.* 1(2): 77-107. 1931.—A useful monograph on inheritance in oats (Avena) including literature up to 1929. The inheritance of various characters is briefly discussed under the following headings: color inheritance, ear characters, grain characters, other morphological characters, and physiological characters. A list of *Avena* characters which have been genically analyzed is included. Linkage relations are discussed and a bibliography of 79 titles is appended.—*R. J. Garber.*

15222. **MILLER, JULIAN C.** **A study of mutations of the Porto Rico sweet potato.** *Proc. Amer. Soc. Hort. Sci.* 27: 343-346. 1930(1931).—The sweet potato very seldom produces viable seed in the United States, and since so very few records are available showing definite facts of introduction, it is the belief that many of the varieties have originated in this country by means of somatic mutations. The work reported in this paper has been confined to the Porto Rico type and to date the following mutations have been assembled: (1) White skin; (2) White flesh; (3) White skin and white flesh; (4) White striped; (5) Gold skin; (6) Purple skin and (7) Vineless or bunch. These variations produce potatoes according to their likeness. Some of the mutations show significant difference in yield and chemical composition from the normal parental type. Selection of desirable mutations offers a practical means of sweet potato improvement in the United States.—*J. C. Miller.*

15223. **MIYAKE, KIICHI, YOSHITAKA IMAI, and KIYOO TABUCHI.** **Contributions to the genetics of Phaseolus vulgaris.** *Jour. Coll. Agric. Imp. Univ. Tokyo* 11(1): 1-20. 2 col. pl., 1 fig. 1930.—Two recessive genes give green stem. The dominant allelomorphs are complementary in giving a colored stem. Pink stem is recessive to red. Red flowers are borne on red stems and pink flowers on pink stems. Green stems may also bear these colors in addition to flecked and white flowers. Thus the factors for stem color are not complementary in their effect on flower color. Flecked and white flowers are simple recessives to self color. Piebald seed marking is recessive to self color. Three possible modifiers affect extension of piebald color. Speckled and mottled types are dominant over plain color. A gene for cream color is linked with a gene for mottled pattern with a recombination value of 2.6 per cent. Two complementary genes when recessive produce cream. Mottled pattern does not appear in cream or white beans. All seed-coat colors are hypostatic to black. Brown also conceals all colors except black. Purple, red, gray and yellow colors are manifested by respective genes. All colors are concealed in cream and white genotypes.—*T. M. Currence.*

15224. **MOLDENHAWER, KONSTANTY.** **Studja genetyczne nad mięszańcami ♀ Triticum dicoccum × ♂ Triticum dicoccoides. [The cross between T. dicoccum and T. dicoccoides.]** [With French summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest Ann.)* 22: 189-212. 4 pl., 9 fig. 1929.—When *T. dicoccum* (beardless) was crossed with *T. dicoccoides* (bearded) the F_2 were of 5 kinds as regards head type: *T. dicoccum;* new types of *T. dicoccum* (bearded); *T. dicoccoides,* proper; new forms which cannot be classified among any of the existing spp.; and *T. ellipticum* Mal. The parent types were in a great minority. The form of the head in F_2 showed considerable segregation, at the same time causing a series of new types to appear. The bearded hybrids were dominant over the beardless plants. In F_2 a segregation occurred in the ratio of about 18 bearded to 1 beardless. The distinctive character, consisting in hairiness of the rachis (characteristic of wild grains), is caused by 2 genetic factors in the parent types, of which one is epistatic and the other hypostatic; and the experimental ratio of the segregation corresponds exactly to the theoretical 15:1 in the F_2 and F_3 of this cross. The velvety character of the glumes is dominant in the F_1, F_2, and F_3, the segregation ratio being 3:1.—*Author's summary (transl.).*

15225. **MORGAN, W. P.** **Flower forms in hybrid Freesias.** *Jour. Heredity* 21(12): 482-488. 5 fig. 1930.—Several unusual types are figured and described, including: doubles with and without petaloid stamens; a giant mutation of the extra-chromosome type; and unusually large flower heads. All are from seedlings derived from uncontrolled hybridizations.—*L. M. Dickerson.*

15226. **MUMM, W. J., and C. M. WOODWORTH.** **A factor for soft starch in dent corn.** *Jour. Heredity* 21(12): 503-506. 2 fig. 1930.—In a line of inbred corn in which the ears had been consistently horny in endosperm composition, an ear was found with decidedly starchy endosperm. The starchy condition has continued to breed true. In crosses with horny dent corn, starchy has behaved as a recessive. Plants from starchy seeds are normal. Crosses with floury gave horny kernels. A hybrid between starchy and horny, crossed with a hybrid between floury and horny, gave only horny seeds; the hybrid between starchy and horny, crossed with homozygous floury, also gave only horny. Starchy corn is not a defective type. Compared with horny, it is as resistant to scutellum rot, the seed is as large and as viable, the seedlings are as vigorous, and the mature plants as productive. Starchy seeds were slightly lower in protein, but significantly higher in oil than horny. The symbols *H h* are proposed for this character pair.—*W. J. Mumm and C. M. Woodworth.*

15227. **MÜNTZING, ARNE.** **Einige Beobachtungen über die Zytologie der Speltoidmutanten.** *Bot. Notiser* 1930(1): 35-47. 14 fig. 1930.—This paper reports results of cytologic studies made in 1927 on speltoid material. Normal reduction division was observed in certain plants and in others various disturbances, the most striking of which were the vagabonding univalent chromosomes. The types studied were classified into "labile" and "stabile," according as to whether irregularities occurred or not. Of the 41 plants investigated, 23 were stabile and 18 labile. The labile types further were classified mor-

phologically and found to be heterozygous. The stabile plants apparently were homozygous with certain exceptions. 41 chromosomes were found in plants of the B-speltoid series; 43 in the C-speltoid series, in agreement with the results of Huskins; 43 also were found in a sub-compactum plant. Trivalent and quadrivalent complexes were not observed. Winge and Huskins assumed that speltoid types originate through faulty chromosome conjugation. Nilsson-Ehle believes that speltoids are caused in the speltoid complex by mutation in one chromosome. The author suggests (at the instance of Nilsson-Ehle) that the chromosome complications may be caused secondarily by deficiency mutation in the speltoid factor complex. This presumably weakens the affinity between the mutating chromosome and its normal partner, resulting in the formation of trivalents, quadrivalents, open chains, etc. The various chromosome anomalies are discussed. The cytologic facts known at present neither verify nor disprove the theory of Winge. Further intensive genetic and cytologic studies are necessary to clear up the speltoid problem.—*V. H. Florell.*

15228. **NEWTON, W. C. F. The inheritance of flower color in Papaver rhoeas and related forms.** *Jour. Genetics* 21(3): 389-404. 5 col. pl. 1929.—Posthumous paper prepared by J. B. S. Haldane, J. Philp, Lily Newton, and H. G. Osterstock. In addition to *P. rhoeas,* the var. *violaceum,* the horticultural form *P. hookeri,* and the Shirley poppy were studied. Gene *C* converts white or pale flower to fully colored; *P,* mauve or purple to pink or red; *B,* produces basal blotch, intensifies petal color and converts light filaments to black; *T* (in absence of *B*), tinges filaments and darkens petals; *W,* produces white-edged petals; *F,* converts pink to rose crimson, darkens mauve, and flushes light-centered flowers; *R,* converts pink to rose pink and crimson to cherry. *WRB* show linkage as do *PFT* but *C* is independent. The haploid chromosome number is 7.—*L. L. Burlingame.*

15229. **NIEVES, RAIMUNDO. Investigaciones sobre la herencia de los caracteres en el trigo. (2nd contrib.) Herencia del hábito de crecimiento. [Inheritance in wheat. 2. Inheritance of the growth habit.]** *Rev. Fac. Agron. Univ. Nacion. La Plata* 19(1): 64-70. 1929.—Kanred, a hard red winter wheat, with prostrate winter habit, resistant to stem rust, leaf rust, and both species of bunt, was crossed with Florence, an early, erect, spring wheat very resistant to both species of bunt. The growing F_1 plants were all erect like the spring wheat parent. In F_2 the growing plants segregated in a monohybrid ratio, 3 erect to 1 prostrate. No other character inheritances were reported.—*W. W. Mackie.*

15230. **PEARSON, O. H. An albino mustard.** *Jour. Heredity* 21(5): 221-223. 1 fig. 1930.—A plant of a variety of *Brassica campestris* introduced from China as S. P. I. No. 63161 produced albino progeny in the ratio of about 3 normal to 1 albino.—*O. H. Pearson.*

15231. **RAMIAH, K. The inheritance of characters in rice, part III.** *Mem. Dept. Agric. India. Bot. Ser.* 18(7): 211-227. 10 pl. (2 col.) 1930.—With respect to habit of growth, cultivated rices are placed in 2 groups, viz., compact and spreading. Inheritance studies show that spreading habit of growth is dominant to compact, and segregation occurs in a ratio of 3 : 1. A yellow chlorophyll deficiency was shown to be recessive and due to duplicate factors, giving a ratio of 15 green plants : 1 yellow. A plant of hybrid origin is described producing purple- and green-glumed spikelets on the same panicle. This plant (and family) was a simple chimera. One line with a lethal factor was isolated from this family which gave 2 plants with purple to 1 with green glumes.—*J. W. Jones.*

15232. **RAMIAH, K., S. JOBITHARAJ, and S. DHARMALINGA MUDALIAR. Inheritance of characters in rice, part IV.** *Mem. Dept. Agr. India Bot. Ser.* 18(8): 229-259. 7 pl. (1 col.), 1 fig. 1931.—The characters studied include glutinous endosperm, size and shape of grain, lax and dense panicles, clustering spikelets, dense arrangement and clustering of spikelets, "mottling" over fertile glumes, size of outer glumes, and brown rice. The common and glutinous rice endosperm characters form a simple pair of allelomorphs. In F_1 common and glutinous pollen grains are produced in equal numbers. Selfed F_1 plants, however, often result in a significant deficiency of glutinous kernels. Back crossing indicates that glutinous pollen is weaker than the common. Other experiments indicate that unfavorable environmental conditions may result in a deficiency of glutinous pollen grains. Glutinous grains are less viable than common grains, and glutinous seedlings show lack of vigor. In natural and artificial crosses, short spikelet behaved as a simple dominant to long. Segregation for panicle density gave about 3 lax to 1 dense panicle. In a cross between parents having clustered and normal spikelet arrangement, the F_1 was intermediate and in F_2, 3 groups were present—clustered, intermediate, and normal—in a ratio of about 1 : 2 : 1. In a cross using varieties with dense and cluster panicles, the F_1 was lax and intermediate for clustering. The F_2 indicates that at least two factors were involved. Length of panicle and emergence of panicle were controlled by multiple factors. The mottled dirty character proved to be a simple dominant to the even dirty color in lemma and palea. A cross between parents having short and long outer glumes resulted in F_1 with intermediate outer glumes. In F_2 three groups,—short, intermediate, and long outer glumes,—were obtained in a ratio of about 1 : 2 : 1. The pigmentation factor *A* and purple *P* are necessary for the production of purple rice, and, in the absence of *A*, *P* produces brown.—*J. W. Jones.*

15233. **REED, GEORGE M. A new method of production and detecting sorghum hybrids.** *Jour. Heredity* 21(3): 132-144. 7 fig. 1930.—By using pollen from a variety having a dominant seedling color, hybrid seedlings can be isolated after germination, and pollinations can be made by properly bagging the heads and dusting the pollen without emasculation. Heterosis is noticeable in these hybrids. Data are given on the inheritance of smut resistance.—*L. M. Dickerson.*

15234. **ROBERTSON, D. W., and G. W. DEMING. Genetic studies in barley.** *Jour. Heredity* 21(6): 283-288. 3 fig. 1930.—The following chlorophyll-deficient seedling types were described, Chlorina ($Fc\ fc$) in Colsess barley, yellow ($Xc_2\ xc_2$) in Coast barley, white ($Ac_2\ ac_2$) in Coast barley, and Virescent ($Yc\ yc$) in Coast barley. All of the above characters were found to be recessive to normal green and each dependent upon a single factor difference. The factor pairs ($Fc\ fc$), ($Xc_2\ xc_2$), ($Ac_2\ ac_2$) and ($Yc\ yc$) were inherited independently of the factor pairs ($Ac\ ac$) for green versus white seedlings and ($Xc\ xc$) for green versus xantha seedlings previously studied. The factor pair ($At\ at$) for green versus white seedlings in Trebi is inherited independently of the factor pair ($Fc\ fc$) for chlorina seedlings and ($Fc\ fc$) is inherited independently of the factor pairs ($Xc_2\ xc_2$) and ($Ac_2\ ac_2$). A three factor difference was found between the smooth style of Lion and the feathered style of Coast. The factor pairs are designated as *G.g., G'.g', G".g".*—*D. W. Robertson and G. W. Deming.*

15235. **ROBINSON, T. RALPH. A chimera in the Poinsettia.** *Jour. Heredity* 22(11): 359. 1 fig. 1931.—The stem and bracts show distinct color demarcations. The flower had 24 bracts, of which 13 were pink, 10 red and one divided with red on one side and pink on the other side of the midrib.—*L. M. Dickerson.*

15236. **RUDORF, WILHELM. Aspectos genéticos del problema de la inmunidad en las plantas cultivadas.** *Argentina Min. Agric. Sec. Propaganda e Informes* 799. 1-6. 2 col. pl. 1930.—The author surveys investigations on specialization of rusts from Eriksson up to the recent experimental work of E. C. Stakman, E. B. Mains and others. He discusses the specialization of both parasites and host plants from the standpoint of genetics. Examples of methods in genetics and of rust immunity in wheat are given. The author discusses the importance of parallel investigations of varieties resistant to groups of biotypes of more than one species of parasite with the object of establishing, if this does not already exist,

a combined resistance in one variety to groups of biotypes of another species of parasite. He found such combined resistance to biotypes of *Puccinium glumarum tritici* and of *P. triticina* in the wheat varieties: Normandie, Blausamtiger Kolben, Hard Taganrog (9 H 39 Percival) and in one *Triticum monococcum* type. (Beiträge zur Immunitätszüchtung gegen Pucc. glumarum tritici Streifenrost des Weizens, Phytopathologische Zeitschrift, Bd. I, 465-525. Berlin, Parey 1929).—*W. Rudorf.*

15237. **SCHIEMANN, ELISABETH. Über eine praktisch und phylogenetisch wichtige Mutation bei Gerste nebst einigen Bemerkungen über Mutation bei Getreide.** *Ber. Deutsch. Bot. Ges.* 48(10): 477-489. 4 fig. 1930.—A dwarf type of barley is described in detail. It occurred as a mutation from normal 2 row. The new mutant has a noticeably shorter beard than normal barley.—*D. W. Robertson.*

15238. **SHAMEL, A. D. A bud variation in the Deglet Noor date palm.** *Jour. Heredity* 21(4): 164-166. 2 fig. 1930.—In a Deglet Noor tree planted as an offshoot, several leaves developed from one sector of the trunk which have broad flat pinnae instead of the narrow folded pinnae characteristic of the Deglet Noor. Some leaves have the broad pinnae on one side of the midrib with normal pinnae on the other side. A fruit bunch arising from the mutating sector bore dates of a somewhat abnormal form which were late in ripening.—*C. S. Pomeroy.*

15239. **SINGLETON, W. R., and D. F. JONES. Heritable characters in maize. XXXV—male sterile.** *Jour. Heredity* 21(6): 266-268. 1 fig. 1930.—A factor causing the tassel to be sterile was found in *Zea mays.* This factor, ms_1, is closely linked with the *Y* locus, showing 4.5 percent crossing over. It shows a linkage value of about 28 percent with *Pl.*—*W. R. Singleton.*

15240. **STADLER, L. J. Some genetic effects of irradiation in plants.** *Jour. Heredity* 21(1): 3-19. 14 fig. 1930.—Among "visible" mutations of barley induced by irradiation, about 90% are recognizable in the seedling stage. No dominant mutations were found. Three cases of apparently direct cytoplasmic effect, resulting in striping of the treated plant, were found. In maize, mutation is induced similarly. In wheat and oats, comparable doses induce few or no mutations. In dormant seed of barley, mutation was induced at a rate approximately ¼ that found in actively germinating seed. In seed soaked but not aerated, the mutation rate under irradiation is not significantly higher than in dormant seed. Temperature during irradiation (10-50° C.) had no appreciable effect on mutation rate. Mutation frequency was directly proportional to radiation intensity, within the limits of sampling error, both in dormant and in germinating seeds. X-rays at 40, 56, 81, 98, and 112 K.V.P., applied in equal intensity, induced mutation at approximately the same rate. Mutations were induced also by "grenz rays" (ultra-soft x-rays) at 7 K.V.P. Chromosomal aberrations in endosperm development occur normally with frequency varying, for loci studied, from .05% to 0.59%. The frequency is increased more than 20-fold by x-ray treatment. In ears x-rayed shortly after fertilization, chromosome aberrations occur with high frequency also in the embryo, producing partial sterility and defective plants. In plants heterozygous for plant characters, sectors showing the recessive character are produced. Similar chromosomal effects are produced by irradiation of pollen.—*Author's abstract.*

15241. **STADLER, L. J. Recovery following genetic deficiency in maize.** *Proc. Nation. Acad. Sci. U. S.* 16 (11): 714-720. 1930.—Deficiency is the loss or inactivation of a section, or the whole, of a chromosome. Recovery is defined as the return to normal activity of genes previously deficient. Tassels of plants homozygous dominant for *A R C Wx* and *Pr* were treated to x-rays and the pollen used on plants of the genetic composition *a R C pr.* Among 3916 seeds produced 27 were colorless, indicating loss of *A,* and 9 were red, indicating loss of *Pr.* In addition, 18 seeds were colorless except for one or more small, colored spots, and 4 were red except for similar spots of purple. The average area showing the dominant character was less than 1/100 of the endosperm surface. The same treated pollen used on plants of *A R c wx* produced 2374 seeds of which 27 were colorless (18 white waxy and 9 white horny). In addition there were 5 white waxy seeds with small spots of colored horny tissue. The fact that the recovery in every instance affected both characters simultaneously is held to preclude reverse mutations as an explanation. Reasons are given against explaining the occurrence of the small spots as extreme examples of chimera. Recovery was observed also in untreated material. In 700 examples of endosperm chimeras, there were several cases in which small spots occurred in the deficient sector and 11 seeds with the entire endosperm deficient except for one or more small spots. The frequency of deficient endosperm showing recovery was as high in the untreated as in the treated seed. One example of recovery in the sporophyte is reported,—a green plant deficient for *A* that developed narrow red stripes on the lower leaf sheaths. A suggested mechanism providing for recovery is that deficiency deprives the chromosome of its power to reproduce itself without destroying its other functions. If later the ability to divide is restored, the cell descendants would constitute an island of tissue showing the dominant character.—*G. N. Collins.*

15242. **TERASVUORI, KAARLO. Hernemuodoista. [Forms of peas.]** [In Finnish, with German abstract.] *Maataloustieteellinen Aikakauskirja* [*Helsingfors*] 1 (3/4): 105-116. 1929.—Over 2000 selections were isolated from among about 70 samples of field peas. These were studied over a period of 3 years and found to be pure lines with 1 exception of a cross supposedly caused by insects. The material represented over 80 different form-groups based on such characters as principal color of flower, seed coat, and hilum; seed weight, earliness, and number of ovules per pod. When additional factors were considered, 170 groups could be distinguished. The crossing experiments of Nilsson-Ehle have shown that the operation of the well-known independent Mendelian factors can develop additional factors that can produce either a definite, separate, external character or change the apparent action of other factors. If through crossing one could combine all the last mentioned characters and the 13 factorial pairs recognized as early as 1908, in all possible ways, 1 to 2 million constant forms would result. Not all these combinations are possible in practice, but on the other hand there are many unmentioned characters which would greatly increase the number of possible forms. If all these characteristics are considered by recognizable differences of degree as well as kind, the number of theoretically possible constant forms of peas becomes inconceivable. This also holds for other self-fertile plants.—*V. R. Boswell.*

15243. **TJEBBES, K. Two linkage groups in the garden bean.** *Hereditas* 15(2): 185-193. 1931.—Two cases of linkage are reported, involving four factors determining seed coat color. *B* together with the basal factor *A* gives a pale yellow which is mottled in the heterozygote. *R* with *A* gives a wine red color, with *A* and *C* the color is burgundy red. *S* restricts the red pigment to stripes and patches. The factor *G* is a member of the allelomorphic series *Gr-G-g,* giving green foliage and pods, green foliage and yellow pods, and yellow foliage and pods, respectively. *B-R-S* are strongly linked in one group, with less than 1% crossingover. *C* and *G* are loosely linked, in another chromosome, with about 35% of crossingover.—*H. Wexelsen.*

15244. **WATERHOUSE, W. L. Australian rust studies. III. Initial results of breeding for rust resistance.** *Proc. Linnean Soc. New So. Wales* 55(5): 596-636. 3 pl. 1930.—Under conditions prevailing at Sydney University the best results in wheat crosses were obtained by pollinating 2 days after emasculating. An efficiency of 75% may be looked for. Pollination of flowers on severed stems

resulted in the production of viable grains. 1932 pollinations of wheat with barley pollen failed to produce hybrid seed. In crossing wheat and rye, no success has attended efforts to secure fertile progeny. The sterile F_1 seedlings were resistant to stem rust forms to which the wheat parent was susceptible. Owing to sterility in the F_1 little is to be gained from attempts to cross *T. vulgare* wheats directly with Khapli. There was incomplete dominance of resistance to stem rust in the F_1 of Federation-Khapli crosses. In *T. vulgare* × *T. durum* crosses, the resistance of the durums to stem rust is due to one main dominant factor. In a cross between Canberra and Thew wheats, resistance was obtained to 6 forms of *P. graminis tritici*. Each parent possessed a dominant factor for resistance to three different forms of stem rust. In the F_2 a 9:3:3:1 ratio was obtained for resistance to the 2 groups of rust forms. The inheritance of resistance to a form of *P. triticina* in this same cross was due to a single dominant factor, which is inherited independently of the 2 factors for resistance to *P. graminis tritici*. In the variety Thew, an additional independent dominant factor for resistance to *P. triticina* is present, and is linked with a factor for resistance to a form of *Erysiphe graminis*. Japanese Bearded also contains a single dominant factor for resistance to leaf rust. General results from a number of wheat crosses show that the inheritance of resistance to Forms 43 and 46 of *P. graminis tritici* is due to a single dominant factor. The inheritance of resistance to Form 34 is due to one or more factors, with dominance of susceptibility. Some work on inheritance of resistance to *P. graminis avenae* points to a single dominant factor for resistance. In many of the wheat crosses, the inheritance of the "grass clump" habit has been recorded. Grass clumps may occur in the F_1 and lead to sterility. In other crosses, counts in the F_2 show a ratio of 13 normals: 3 grass clumps, or of 15 normals: 1 grass clump. —*O. S. Aamodt.*

15245. WHITAKER, THOMAS W. Sex ratio and sex expression in the cultivated cucurbits. *Amer. Jour. Bot.* 18(5): 359-366. 1931.—Studies of sex expression in 49 varieties, representing 8 spp. and 4 genera, indicate that each species is characterized by a specific qualitative type of sex expression. In some species, there are varieties which qualitatively differ from the characteristic type. *Cucumis melo*, in most of its varieties, is andromonoecious, but its variety, Mexican Banana, is monoecious. Within a given species quantitative differences in sex expression may exist between its varieties, this being expressed in the ratio of staminate to pistillate flowers produced over a given period. Staminate flowers are greatly in the majority at all times in all forms studied. There is some evidence that environmental control of sex expression may be possible and practical.—*T. W. Whitaker.*

15246. WINGE, Ø. X and Y linked inheritance in Melandrium. *Hereditas* 15(2): 127-165. 16 fig. 1931.—In 1917 Winge reported a case of inheritance of chlorina in *Melandrium* supposed to be Y-linked. Later investigations showed that the character is X-linked and lethal when homozygous, killing all chlorina females. The character is therefore called "aurea." All aurea plants are ♂♂, yellowish green with unevenly colored leaves. In spite of difficulties on account of cooperation of autosomal and sex-linked genes, the experiments reported made clear the inheritance of aurea: a recessive gene in the X chromosome (*au*) with an autosomal inhibitor *A*. Females homozygous for *au* but carrying *A* are green; without *A* the combination is lethal. Cross combinations of various genotypes of males and females give ratios: 4:3:1, 3:3:1, and 1:1:1 of green ♀♀, green ♂♂, and aurea ♂♂. No aurea ♀ was ever found. A recessive gene *n*, demonstrated both in the X and the Y chromosome in *Melandrium*, gives abnormal plants in which the upper part is pale; the calyx never opens and the petals are completely hidden; it is less viable than the normal. Three autosomal inhibitors have been demonstrated (*G*, *H*, and *I*). Variegated is also inhibited by three autosomal genes, *L*, *M* and *O*, and likewise by the Y chromosome; all variegated plants, therefore, are ♀♀. All these mutants were found in a cross *M. rubrum* × *album*. In the same cross appeared hermaphroditic males. Sex determination and hermaphroditism in *Melandrium* are discussed. Sex is determined by different genes in the X and Y, as well as in the autosomes, exerting influence in the ♂ or ♀ direction. Hermaphrodites are ♂♂ (XY), whose X is strongly ♀ in relation to the Y (X_fY). Further, an autosomal gene *C*, exerting influence in the ♂ direction, may be involved. CX_fY individuals are ♂♂. The constant hermaphrodites found are supposed to maintain themselves on the basis of balanced lethals, having in the X_f chromosome a lethal, *l*. Hermaphrodites segregating ♀♀ and hermaphrodites have the genotype X_fY without any lethal. Exceptional individuals are found in these segregations, and the problem is complicated on account of the existence of autosomal and sex-linked genes of varying strength. *H. Wexelsen.*

15247. YAMPOLSKY, CECIL. Male-female grafts in Mercurialis annua. *Jour. Heredity* 21(2): 65-72. 4 fig. 1930.—Male and female elements can live together in the same graft without apparently influencing the morphological expression of either stock or scion. The existence of ferments or hormones which circulate and influence sex expression in plants is considered impossible because of the development of the reproductive elements in situ.—*L. M. Dickerson.*

ANIMAL (EXCEPT MAN)

15248. BLUHM, AGNES. Über eine entgegengesetzt gerichtete Mutation und Modifikation, bewirkt durch einunddasselbe Agens (Alkohol). *Biol. Zentralbl.* 50 (2): 102-113. 1930.—Six times weekly, ♂ albino mice received injections of 0.2 cc. of 15% ethyl alcohol solution. The F_1 from alcohol-treated males have a greater infant mortality than those of controls. The inbred alcoholic line shows an increasing decline in infant mortality during subsequent generations. In F_2, the rate is only slightly higher; in the later generations, the rate is lower than in control lines. Male offspring from crossmatings of control ♀♀ to ♂♂ from the alcoholic line in any generation have a higher infant mortality than the same generation of controls; ♀ offspring survive with a frequency equal that of controls. Offspring of both sexes from the cross mating of a control ♂ to ♀♀ of the alcoholic line stand a better chance to survive infancy than those of the reciprocal cross or of control lines. Chronic alcohol treatments of the stem ♂ produced hereditary gene mutations in the X and the Y chromosomes that reduce resistance against infant mortality in both sexes. The injured sperm induces a converse modification in the fertilized egg that inhibits the injurious action of the gene mutation and lasts through subsequent generations. Alcoholic ♂♂ mated to control ♀♀ have a high F_1 infant mortality because control ♀♀ do not have this modification. Alcoholic ♀♀ mated to control ♂♂ give the modification to the offspring and their infant mortality is decreased.—*C. P. Oliver.*

15249. BOLEN, HOMER R. A mutual translocation involving the fourth and the X-chromosomes of Drosophila. *Amer. Naturalist* 65(700): 417-422. 1931.—In the "mottled 5" stock of *D. melanogaster* the X-chromosome is broken between white and facet; the left end is attached to the IV. The IV-chromosome is broken between eyeless and bent, and the eyeless part is attached to the right portion of the broken X. This mutual translocation was produced by x-ray. Non-disjunction of IV occurs very frequently. A gene important for viability is located in the left (eyeless) end of the IV.—*H. R. Bolen.*

15250. CASTLE, W. E. Size inheritance in rabbits; the backcross to the large parent race. *Jour. Exp. Zool.* 60(3): 325-338. 6 fig. 1931.—Two races having, respectively, a very large and a very small body size were crossed. F_1 was intermediate. Backcrosses were made between F_1 animals and individuals of both parent races

These groups also were intermediate in size between their parents. Comparison was made of the variability of the five groups (small, large, F_1, ¾ small, and ¾ large) at four different ages; viz., 80, 150, 275, and 365 days. At 80 days the genetic size character of each group was obscured by environmental effects which produced a high variability, except in the F_1 group, where hybrid vigor and good care kept it low. At later ages, the relative genetic variability of each group is clearly revealed. Large and small races are about equally variable. F_1 is less variable than either parent race. The backcrosses produce populations more variable than the parent races or F_1, supporting a multiple factor interpretation. Contrary to expectation, the ¾-large group is not more variable, but rather less so than the ¾-small group. No support is found for the idea that new forces become operative in later phases of growth. Differences observed in the growth curves of the several groups and in the body weights finally attained by them are such as would result from original differences in the developmental rate of the fertilized egg.—*Author (courtesy Wistar Bibl. Serv.).*

Italiano* 15: 499-548. 4 pl. 1931.—Review of literature and description of a fertile ♀ mule in Tripoli. By an ass she produced 2 sterile mules (♂ and ♀); by a stallion 2 fertile horses (♂ and ♀).—*P. Popenoe.*

15252. **COLIN, E. C. A comparison of the descendants of lead-poisoned male guinea-pigs with those from untreated animals of the same closely inbred strains.** *Jour. Exp. Zool.* 60(4): 427-484. 6 fig. 1931.—Over a period of 4 years, 54 ♂ guinea-pigs and 5 ♀ guinea-pigs from two highly inbred and homogeneous lines, derived from single pairs in the 15th and 20th generations, respectively, of straight brother-sister mating, were fed weighed amounts of lead acetate. Symptoms of poisoning were numerous and severe and some, e.g., "cirrhosis" of the liver, were highly constant in occurrence. The life span was materially shortened. In most ♂♂ that died or were killed, motile sperm were found. In only a few cases was marked degeneration of the testis evident. Nearly all the treated ♂♂ produced offspring with normal regularity close to the time of death. Treated ♂♂ were mated with untreated ♀♀ and the 722 offspring compared with 656 offspring from control matings. Untreated offspring from treated ♂♂ were mated and the 269 F_2's compared with controls. Likewise, matings of F_2's were made and the 154 F_3's compared with controls. The effects in experiments with treated ♂♂ and their descendants were in general negative in all respects studied, namely, size and frequency of litter, frequency of abortions and stillbirths, postnatal mortality, birth weight, gain in weight, sex ratio, and the production of abnormalities and mutations. From treated ♀♀ there were indications of an increase in the frequency of abortions, but no evidence of any effect on the few living offspring produced.—*Author (courtesy Wistar Bibl. Serv.).*

15253. **DOBROVOLSKAIA-ZAVADSKAIA, N. Distribution des cas de cancer dans la progéniture d'une souris cancéreuse.** *Compt. Rend. Soc. Biol.* 106(12): 1085-1087. 1931.—A ♀ mouse with mammary cancer mated with a non-cancerous ♂ from a mother with mammary cancer produced 5 ♂♂ all non-cancerous and 8 ♀♀, of which 5 had mammary cancers and 3 were non-cancerous. All of the daughters were mated with brothers. The cancerous produced 29 ♂♂, of which 3 had cancers (non-mammary), and 20 ♀♀, of which 6 had mammary cancers and 1 another type. The non-cancerous produced 17 ♂♂, of which 1 was concerous (non-mammary), and 24 ♀♀, of which 5 had mammary cancer and 2 had other types. These include all young which lived 6 months. The author considers that this indicates a recessive factor for cancer which is usually not manifested in ♂♂, among which mammary tumors are very rare.—*S. Wright.*

15254. **DUNN, L. C., and LORNA W. THIGPEN. The silver mouse.** *Jour. Heredity* 21(12): 495-498. 1 fig. 1930.—Three types of silver coat color, due to a reduction in the number of pigment granules and to their entire absence from certain areas and from entire hairs, are described. Silver gray differs from black and chocolate by a single gene. Pink-eyed Silver did not carry this gene but did carry dilute (*dd*). No close linkage was demonstrated between silver and agouti. The expression varies with age.—*L. M. Dickerson.*

15255. **DUPOND, C. Une nichée d'hybrides intéressante.** *Le Gerfaut* 18(4): 79. 1928.—Of 5 birds composing a single brood of a captive ♀ canary, all appeared to be hybrids, one with a siskin, one with a linnet, and three with a greenfinch.

15256. **ERIZIAN, CHOREN. Das Vorkommen einiger Neubildungen bei Bos taurus in S. S. R. Armenien.** *Zeitschr. Zücht. Reihe B. Tierzücht. u. Züchtungsbiol. einschl. Tiernähr.* 22(1): 114-121. 7 fig. 1931.—The author discusses a few cases of cows with 2 or 3 teats, and tailless animals, found by him and his pupils among native cattle. The taillessness has no relation to sex. The 2-teat cows are more frequent than those with 3 teats. Among the 2-teat cows one had completely lost her back pair of teats, her front pair of teats remaining quite normal. This had no influence whatever on the form and size of the udder. The 2nd cow had an incomplete union of the back and front pair of teats, which were reduced to one pair, while every teat of this pair had 2 milk openings. This had affected the udder and made it small and funnelshaped. The third cow had also the same transformation of the back and front pair into one pair. One of the teats showed a complete union and had one opening, while the other teat was the result of an incomplete union and had 2 openings. The calves of these cows had the normal number of teats. The milk flow of all these cows remained the same as that of normal native cows, the change in the number of teats having not affected the milkflow.—*C. Erizian.*

15257. **GOODRICH, H. B., and I. B. HANSEN. The postembryonic development of mendelian characters in the goldfish Carassius auratus.** *Jour. Exp. Zool.* 59(2): 337-358. 1 pl. 1931.—The development of the characters described by Chen ('28) is traced with special reference to the melanophores and reflecting tissue. Until the 12-mm. stage the history of melanophores is identical in the common goldfish, the transparent shubunkin, and the heterozygous type or true shubunkin. After this stage the number of melanophores increases in the common goldfish, melanophores are destroyed in the transparent shubunkin and show an intermediate condition of partial growth and destruction in the hybrid. The results are numerical, based on counts of melanophores. In the common goldfish, as shown by previous work, the melanophores also degenerate much later in ontogeny (1½ to 17 mo.). In the common goldfish reflecting tissue begins development in certain loci, and spreads until the whole body, excepting fins and pupil of eye, is covered. In the transparent fish very little is developed. In the heterozygous form development starts on the same loci as in the common fish, but growth is early and irregularly inhibited. The total of reflecting tissue of the hybrid is intermediate in amount between that of the 2 homozygous types.—*Authors (courtesy Wistar Bibl. Serv.).*

15258. **GORDON, MYRON, and ALLAN C. FRASER. Pattern genes in the platyfish. Inheritance of naturally occurring color pattern variations on the Mexican killifish, Platypoecilus maculatus.** *Jour. Heredity* 22(6): 168-185. 8 fig. 1931.—Four melanic patterns are described in aquarium-reared specimens; they occur also in the progenitors of the aquarium fishes. Each of the four patterns develops in response to a dominant autosomal gene. They have been called: One-spot, *O;* Two-spot, *T;* Moon, *M;* and Crescent, *C.* There is some evidence that these four dominant factors form an allelomorphic series. Attention is called to the occurrence of polymorphism in this species.—*Author's summary.*

15259. **GOWEN, JOHN W. On chromosome balance as a factor in duration of life.** *Jour. Gen. Physiol.* 14(4): 447-461. 1931.—Under the identical conditions of

the experiment, the type ♀♀ of *Drosophila* live an average of 33.1 ± .6 days; type ♂♂ 28.9 ± 8 days; triploid ♀♀ 33.1 ± .8 days; and sex-intergrade ♀♀ 15.0 ± .3 days. The unbalance of the chromosomes is evidently a fundamental factor in the probable life span of the individual. It has been possible to show by a study of the various sex classifications within the sex-intergrade class that the presence or absence of ovarian or testicular tissue as such is not the primary cause of the difference in the life duration in the type ♂♂ and ♀♀ but that the cause is to be found deeper, sex determination and duration of life accompanying each other and resulting from the common cause, chromosome constitution. The survival curve of the sex-intergrade groups presents a limiting curve of duration of life, a constant death rate for each day of age. Triploid flies are made up of cells which are one-third larger than the cells of the type flies. It is not without significance to note that such individuals show no greater or less duration of life than do the ordinary flies when both groups have their chromosomes in balance.—*Author's summary.*

15260. **GRAVES, R. R. A herediscope demonstration of dairy cattle improvement, illustrating hereditary transmission of milk and percent butter fat with the herediscope.** *Jour. Heredity* 20(9): 431-440. 6 fig. 1929.—Data are presented and methods described for the mechanical demonstration of the manner of inheritance of size and fat production, the effect of selection and the use of proved sires. Other single or multiple factor inheritance may be demonstrated with the same apparatus.—*L. M. Dickerson.*

15261. **GREEN, C. V. Linkage in size inheritance.** *Amer. Naturalist* 65(701): 502-511. 4 fig. 1931.—An analysis of the data on the back-cross generation of a mouse species cross, between large *Mus musculus* with 3 recessive color characters (*dba*) and small *M. bactrianus* with the 3 dominant allelomorphs (DBA^w), has unquestionably shown an association in heredity between factors productive of a large final size in several quantitative characters and a qualitative, brown. This association, found to be statistically significant in four of the 9 adult size characters, was interpreted as genetic linkage and considered as proof that size in mice is influenced by chromosomal genes. To a lesser extent, size in two characters seems to be affected by factors linked with dilution.—*C. V. Green.*

15262. **GUTHRIE, J. E. A color-mutation in Graham's watersnake.** *Jour. Heredity* 21(5): 237-240. 2 fig. 1930.—A *Natrix grahamii,* taken in Iowa, of a hitherto undescribed color pattern, mated before her capture, bore a brood of ten young. Four of these were of her own peculiar (melanic) pattern, while the remaining six were marked with the color pattern characteristic of the species.—*J. E. Guthrie.*

15263. **HAWKINS, L. E., and L. J. COLE. "Porcupine" pigeons. Studies on inheritance in pigeons VIII.** *Jour. Heredity* 21(2): 50-60. 8 fig. 1930.—An abnormal feather structure of pigeons called "porcupine" is described. Barbs and barbules develop imperfectly and later become abraded, leaving in many cases little but the quill. This mutation was found independently in a white Fantail stock, and 13 years later in Homers. "Porcupine" is inherited as a simple mendelian recessive to normal. Some of the birds exhibited sub-normal nervous coordination but this condition is not uniformly characteristic of Porcupines.—*Authors' summary.*

15264. **HUTCHINSON, J. B. A possible explanation of the apparently irregular inheritance of polydactyly in poultry.** *Amer. Naturalist* 65(699): 376-379. 1931.—It is suggested that the excess of four-toed fowls frequently found in F_1, F_2 and backcross following the mating of polydactylous × normal fowls, as observed by Punnett and Pease in their collation of data on polydactyly, may be due to a deficiency in one or both parents of factors necessary for the dominance of polydactyly, rather than to the presence in "resistant" parents of factors inhibiting polydactyly as was suggested by Punnett and Pease.—*F. B. Hutt.*

15265. **HUTT, F. B. Bovine quadruplets including twins apparently monozygotic.** *Jour. Heredity* 21(8): 339-348. 3 fig. 1930.—A case of living bovine quadruplets is reported in which there were 1 bull, 1 freemartin and 2 heifers which were sterile. The bull produced a few calves. The 2 heifers exhibited reversed asymmetry in color patterns. The birth order and foetal membranes suggest that the 2 heifers were monozygotic twins.—*L. M. Dickerson.*

15266. **ILJIN, N. A., and V. N. ILJIN. Temperature effects on the color of the Siamese cat.** *Jour. Heredity* 21(7): 309-318. 7 fig. 1930.—The pattern is a true acromelanism. High external temperature favors the growth of white hair; low external temperature favors pigmentation. The inheritable factor producing the Siamese pattern is designated as C^s (= a_1 of Tjebbes). The differences between the mechanics of pattern development in these cats and also in Himalayan and Marder rabbits are purely quantitative. Physiological factors of heat production and loss also affect the pattern, the threshold of irritation being different for different body parts. Sex differences were found in the thresholds of irritation for back tissue. The change of color of Siamese kittens with age is due to external temperature.—*L. M. Dickerson.*

15267. **INGLEE, CHARLES T., HENRY D. DIXBY, HAROLD OBER, with introduction by J. E. DeMUND. Pure-bred dogs. The breeds and standards as recognized by the American kennel club.** 315p. 92 illus. G. Howard Watt: New York, 1929.—Description and standards of points are given for 89 breeds of dogs grouped as follows: I. Sporting dogs, 17 breeds, including Pointers, Retrievers, Setters, and Spaniels. II. Sporting dogs, 16 breeds including the hounds. III. Working dogs, 16 breeds including sheep dogs, sledge dogs, and other breeds especially adapted for similar work. IV. Terriers, 18 breeds. V. Toys, 14 breeds. Mostly small house dogs. VI. Non-sporting dogs, 8 breeds. Bulldogs and others mostly for pets. Photographs of characteristic specimens of each breed are given. Scale of points and disqualifications are given for most breeds. An illustrated glossary of technical terms relating to dogs is given.—*O. N. Eaton.*

15268. **JOLLOS, VICTOR. Studien zum Evolutionsproblem. 1. Über die experimentelle Hervorrufung und Steigerung von Mutationen bei Drosophila melanogaster.** *Biol. Zentralbl.* 50(9): 541-554. 1930.—Substantiation of Goldschmidt's induction of mutations in the Florida wild type culture of *D. melanogaster* by heat. Abnormalities were obtained from treatment of larvae for 10-12 (later 24) hours at 37° C. More mutations were obtained from a 15 hour treatment at 35-36° C. Three other cultures were compared with the Florida, namely spineless, eosin and sooty, which yielded eosin, sooty, black, aristaless, modification factor for eosin and abnormal abdomen mutations in spineless; black or sooty, modification factor for eosin and abnormal abdomen in eosin; and white, black and abnormal abdomen in coral. No mutations were found in the checks. The author suggests the possibility of directive mutation in successive generations, as indicated by change of red eye to dark eosin, light eosin and finally white, consecutively. Similar indications arose in definite classifications of ebony, sooty, weak-sooty and weaker-sooty body color.—*E. F. Grossman.*

15269. **JULL, MORLEY A., and JOSEPH P. QUINN. The inheritance of black and white in rose comb bantams.** *Jour. Heredity* 20(8): 359-363. 2 fig. 1929.—A pioneer cross in poultry genetics is described and illustrated.—*L. M. Dickerson.*

15270. **JULL, MORLEY A. The association of comb and crest characters in the domestic fowl.** *Jour. Heredity* 21(1): 21-28. 2 fig. 1930.—Five types of crosses involving both the Silkie and Leghorn types of rose comb were used. Apparently the gene for crest (*Cr*) acts as a modifier of comb form. The spiked comb of the Leghorn is shortened in the presence of a crest. Linkage between rose comb and crest seems doubtful in view of the results from these crosses.—*L. M. Dickerson.*

15271. **JULL, MORLEY A., and JOSEPH P. QUINN.**

The production of hen-feathered Brown Leghorns by breeding. *Jour. Heredity* 21(4): 177-186. 7 fig. 1930.—Hen-feathering is dominant to cock-feathering and controlled by a single factor with other modifying factors involved.—*L. M. Dickerson.*

15272. **JULL, MORLEY A., and JOSEPH QUINN. The inheritance of body weight in the domestic fowl.** *Jour. Heredity* 22(9): 283-294. 6 fig. 1931.—The F_2 populations from 3 matings involving reciprocal crosses were more variable in body weight than the F_1 generations. The data suggest dominance, partial or complete, of one or more factors for small body weight in Rose-comb Black Bantams over factors in Barred Plymouth Rocks. The results do not show that body weight is inherited in a simple mendelian manner. It is suggested that many factors may be involved and that for conclusive evidence large F_2 families should be reared from original crosses of highly inbred strains.—*L. M. Dickerson.*

15273. **KEELER, C. E. "Parted parietals" in mice.** *Jour. Heredity* 21(1): 19-20. 2 fig. 1930.—Many mice belonging to a rodless strain bore a well marked median-line separation between the frontal bones. A blood vessel usually emerged through this suture. The study of crosses provided a pedigree of 100 animals, from which it is evident that the character is inherited as a simple dominant. See *Ibid.* 21(2): 83 for correction of terminology.—*Author's abstract.*

15274. **KEELER, CLYDE E. A mutation to dominant spotting (W) in the house mouse.** *Jour. Heredity* 22 (9): 273-276. 2 fig. 1931.—In an unspotted strain of mice there appeared a single individual exhibiting a variegated form of spotting. This spotting depended for its expression upon a single dominant gene, shown by its manifestation in the coat when hybrid and its anemic lethal effect, when purebred, to be identical with the gene for dominant spotting (*W*) commonly present in "black-eyed-white" mice. These experiments indicate that the anemic lethal effect observed in (*WW*) animals is due to the (*W*) gene itself in homozygous form and not to a gene linked with it, because simultaneous mutation in the same two genes on two different occasions would be highly improbable.—*C. E. Keeler.*

15275. **LANDAUER, WALTER, and L. C. DUNN. The "frizzle" character of fowls.** *Jour. Heredity* 21(7): 290-305. 7 fig. 1930.—Experiments with English and American breeds show the difference between frizzled and non-frizzled plumage to be due to a single factor pair. Frizzling is dominant and has no lethal effect. Frizzle fowls bred for exhibition are generally heterozygous and show a higher degree of frizzling than outcrossed F_1 stock. Feathering is much delayed in Frizzles; exhibition and F_1 types differ microscopically in barbule abnormalities. Embryonic mortality and hatchability are normal except where either exhibition type or homozygous frizzle females are used. The basal metabolism is probably increased in Frizzles; in homozygous stock, sterility is high, susceptibility to adverse environmental conditions is increased and a high percentage of both sexes never come to maturity. Spermatogenesis appears to be normal wherever ♂♂ reach maturity.—*L. M. Dickerson.*

15276. **LITTLE, C. C. The effects of selection on eye and foot abnormalities occurring among the descendants of x-rayed mice.** *Amer. Naturalist* 65(699): 370-375. 1931.—By a series of experiments involving close inbreeding, it is shown that four sub-lines of a race of abnormal mice can be produced by selection. These are (1) a line overlapping normal in somatic appearance in almost 100%, (2) a line in which foot abnormalities have disappeared and eye abnormalities are retained in almost 100%, (3) and (4) lines in which eye and foot abnormalities are present, one showing a relative preponderance of abnormalities of the front feet, the other showing a preponderance of abnormalities of the hind feet.—*C. C. Little.*

15277. **LOEB, LEO, and HUGH C. McPHEE. Transplantation of tissues in hybrids of inbred families of guinea pigs and the individuality differential.** *Amer. Naturalist* 65(700): 385-405. 1931.—If, instead of transplanting tissues from one member of an inbred family of guinea pigs to another member of the same family, we transplant from a hybrid between two inbred families to another hybrid of the same kind, the results become more unfavorable, in accordance with the greater difference in average genetic constitution between host and donor to be expected under these conditions. In accordance with expectation the average of the results obtained in this series of transplantations, as a whole, is much superior to ordinary homoiotransplantations and corresponds approximately to the results of ordinary (brother to brother) syngenesiotransplantation. The result of transplantations between hybrids of the same inbred families, when donor and host are brothers or sisters, is much superior to ordinary syngenesiotransplantations in non-inbred families, but is somewhat less favorable than transplantations between non-hybrid brothers belonging to the same inbred family; these results are also in accordance with differences in the genetic constitution in such animals. In accordance with expectation, transplantation from hybrids between inbred families to non-related guinea pigs, either non-inbred or representing hybrids between two inbred families other than those used for the first hybridization, gives ordinary homoio-reactions. We may assume that the severity of the reaction against the transplant is determined by the number of strange gene-derivatives which are introduced with the transplant into the host and by the degree of their strangeness.—*L. Loeb.*

15278. **LUSH, JAY L. An impressive case of atavism in Jersey cattle.** *Jour. Heredity* 20(8): 381-383. 2 fig. 1929.—A cow is described whose very dark fawn color and few white markings were reproduced with unusual fidelity in a granddaughter, although the intermediate relative was a very light golden fawn with an unusually large amount of white markings. This case, while probably not new in principle, illustrates well the value of pedigree study in estimating the breeding value of animals which have not yet produced enough progeny for their breeding value to be proved.—*J. L. Lush.*

15279. **LUSH, JAY L. Duck-legged cattle on Texas ranches.** *Jour. Heredity* 21(2): 85-90. 2 fig. 1930.—Hereditary short-leggedness found in high grade Hereford cattle on several ranches is described. This dwarfness is similar to and may be identical with that found among the Dexter cattle of Ireland. Probably it is a simple Mendelian dominant kept through selection while many generations of grading up with normal Hereford bulls took place. Detailed breeding data and ratios were not available.—*J. L. Lush.*

15280. **LUSH, JAY L. Earlessness in Karakul sheep.** *Jour. Heredity* 21(3): 107-112. 6 fig. 1930.—Ear length is largely determined by one pair of genes not showing dominance. Extremely long and extremely short ears appear to be homozygous for this factor pair, while the intermediate or "short" ears are heterozygous. The results agree rather closely with those reported by Ritzman, Wriedt and Wassin.—*J. L. Lush.*

15281. **LUSH, JAY L. "Nervous" goats.** *Jour. Heredity* 21(6): 242-247. 3 fig. 1930.—A form of temporary but complete paralysis induced by surprise or fright is described as characteristic of an entire flock in western Texas. These goats had been entirely descended from animals brought from central Tennessee where the same sort of behavior has been reported previously. Inheritance is clearly indicated but nothing is known about the number of factors involved. Reference is made to similar nervous disorders in other mammals.—*J. L. Lush.*

15282. **McPHEE, HUGH C. Swine inbreeding at the United States Department of Agriculture—a progress report.** *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 131-134. 1930(1931).—Inbreeding by brother-sister mating has been carried on for 4 generations with Chester White and Tamworth, for 2 generations with Poland China swine. One of the important results is the segregation of inherited differences not apparent in the foundation stock. Among these are a recessive dilution

factor for the black of the Poland China which is apparently linked with spotting; swirls in Tamworths; belting factors in both the Chester White and Tamworth breeds; segregation of type. In general, mortality was greater and there was less vigor among the inbred stock than among the controls, but there were wide variations among different lines in this respect.—*H. C. McPhee.*

15283. **METZ, CHAS. W. Sex determination in Sciara.** *Amer. Naturalist* 63(689): 487-496. 1929.—Information, already published, on sex determination in *Sciara* (Diptera) is summarised. Cytological data are mainly from 5 spp.; genetic data mainly from 2, *S. coprophila* Lint. and *S. impatiens* Joh. The author's conclusions are: Sex determination (in the broad sense) involves two distinct series of phenomena: (a) determination of the sex of the progeny as a whole, (b) determination of the sex of the individual. Sex of the progeny is determined by the zygotic constitution of the ♀. Presumably, ♀-producing ♀♀ are *Aa*, ♂-producing ♀♀ *aa* and ♂♂ *aa*, *A* and *a* representing either chromosomes or genes. Sex of the individual is determined by a pair of sex chromosomes (XX ♀, XY ♂), *A* and *a* are probably "in" the X-chromosome or associated with it. "Unisexual" progenies are apparently the result of a selective elimination (inactivation) of sperms, not of zygotes. The "precocious" chromosome is probably not a sex chromosome. Although the exact rôle of the "sex limited" chromosomes is unknown, they are apparently not directly concerned in sex determination.—*F. G. Holdaway.*

15284. **METZ, C. W. Unisexual progenies and sex determination in Sciara.** *Quarterly Rev. Biol.* 6(3): 306-312. 2 fig. 1931.—Two types of reproduction are found in Sciara. (1) "Digenic," in which progenies are essentially bisexual; (2) "Monogenic," in which progenies are unisexual. Thirteen species have been studied, 6 extensively, 7 slightly. Of the former, 3 show digenic and 3 monogenic reproduction. In some species both types of reproduction are found. Sex ratios in digenic type are variable, not consistently 1:1. Genetic difference between the two not yet analysed. Sex determination involves two aspects: (1) sex of progeny as a whole and (2) sex of individual fly. Former is determined by the sex chromosomes of mother, ♂-producing ♀♀ being XX and ♀-producing ♀♀ being X'X. Genetic tests indicate that X and X' chromosomes are similar, but not identical in constitution. Not yet certain how sex of individual is determined. Sex-linked inheritance of Drosophila type is found. Male germ-line has 2 sex chromosomes, indicating XY constitution and a process of selective fertilization. But in both sexes certain chromosomes present in the germ-line are absent from somatic cells. Male soma lacks one more chromosome than female. Latter chromosome is presumably a sex chromosome (always the paternal one), which suggests that sex may be determined by constitution of soma and that ♂ germline may be XX, like the ♀. On this view, sex of individual would be determined at time of chromosome elimination from somatic nuclei during cleavage. Certain large chromosomes are apparently limited entirely to germ-line in both sexes; presumably their function is similarly limited.—*C. W. Metz.*

15285. **METZ, CHAS. W., and M. LOUISE SCHMUCK. Unisexual progenies and the sex chromosome mechanism in Sciara.** *Proc. Nation. Acad. Sci. U. S. A.* 15(12): 863-866. 1929.—Evidence from *Sciara coprophila* Lint. indicates that sex of the individual and sex of the progeny as a whole are "determined" by sex chromosomes: X, X', and Y. The chromosome combinations are: (1) ♂ XY; (2) ♂-producing ♀ XX (homozygous for the X found in the ♂); (3) ♀-producing ♀ XX'. X' differs from X in respect to the agent responsible for "sex of progeny." The X' descends directly from mother to daughter; X passes back and forth between the ♂ and both kinds of ♀♀.—*M. L. Schmuck.*

15286. **METZ, CHAS. W., and M. LOUISE SCHMUCK. Further studies on the chromosome mechanism responsible for unisexual progenies in Sciara. Tests of "exceptional" males.** *Proc. Nation. Acad. Sci. U. S. A.* 15(12): 867-870. 1929.—A preceding paper has shown that XX ♀♀ and X'X ♀♀ are not alike from the standpoint of sex determination. Additional experiments were performed to determine whether X'Y ♂♂ occurred and if so whether they exhibited the expected type of genetic behavior. A sex-linked mutant character carried in the X chromosome was used, in order to distinguish the ordinary XY type ♂ from the exceptional X'Y type. Experiments were performed to determine whether the X'Y type ♂ transmitted the X' to his daughters, making them all ♀-producers instead of 50% ♀-producers and 50% ♂-producers, as would be the case if an ordinary ♂ were used. This was found to be the case. In the next generation, using XY ♂♂, the progenies were all ♀ but 50% of the ♀♀ were female producers and 50% male producers as usual. The observations throw some light on the nature of the X' chromosome and its relation to X. Perhaps the most significant feature is the fact that X' may be substituted for X in both ♂♂ and ♀♀ without any conspicuous effect on external morphology, viability or fertility of the flies, although it is evident that in nature X'Y males and X'X' females are relatively uncommon.—*M. L. Schmuck.*

15287. **MULLER, H. J. Types of visible variations induced by x-rays in Drosophila.** *Jour. Genetics* 22(3): 299-334. 3 col. pl., 15 fig. 1930.—Changes produced in the germ plasm of *Drosophila* by x-rays fall roughly into three classes: point mutations, changes due to the altered "dosage" of genes, and "eversporting displacements." The induced point mutations are apparently the same as spontaneous mutations. Some x-ray mutations seem identical with previously known spontaneous ones. Others represent new allelomorphs of known loci. Still others affect loci not known to mutate spontaneously. Mutations first described in this paper are: carnation eye color, located in the X-chromosome near bobbed; snipped wings, a dominant allelomorph of vestigial; a dominant allelomorph of eyeless; prickly bristles, a 3rd chromosome dominant located 15 units from the right; and outstretched wings, a sex-linked recessive located a few units to the left of carnation. Altered dosage of genes is due to duplications or deficiencies for certain sections of chromosomes. Duplications and deficiencies arise either directly under the influence of x-rays, or indirectly, as a result of translocations or of crossing-over between chromosomes having induced genic rearrangements (inverted sections). Duplications for sections of the x-chromosome, if they involve long sections, produce more deleterious effects in ♂♂ than in ♀♀. The addition of a whole X-chromosome to the chromosomal complement of a normal ♂, however, results in its transformation into a ♀. The deleterious effect of duplications on ♂♂ must be due, therefore, to "intrachromosomal" rather than to "interchromosomal" genic disproportions. Known duplications for various sections of the X-chromosome do not affect the sexual characteristics, and the conclusion is drawn that sex is determined "by one or a few specific genes" lying in the portion of the X-chromosome not covered by the known duplications. The eversporting displacements manifest themselves as mutations whose characteristics are unstable. They vary both germinally and somatically. This variation results in some cases in splitting off of types more and less extreme than the original "mutations." The somatic variations are mosaics, most readily detected in eye color, but seen also in other parts of the body. Eversporting displacements in most cases are connected with various kinds of chromosomal aberrations, like translocations, inversions or deficiencies. Mutability in eversporting displacements affects frequently several neighboring loci. This fact suggests that "eversporting" is due to processes involving units larger than genes. No satisfactory explanation can be given at present to eversporting displacements but several suggestions are given.—*T. Dobzhansky.*

15288. **MULLER, H. J., and L. M. MOTT-SMITH. Evidence that natural radioactivity is inadequate to explain the frequency of "natural" mutations.** *Proc. Nation.*

Acad. Sci. 16(4): 277-285. 1930.—It has been shown by Hanson that the number of mutations caused by radiations is directly proportional to the ionization which these radiations produce. In attempting to discover whether natural radioactivity is sufficient to account for the "natural" rate of mutation in an animal like *Drosophila*, the authors have, therefore, attempted to measure the ratio of ionization from natural radioactivity to which these animals are exposed to the ionization to which they are exposed in irradiation experiments. This ratio is then compared with that of the number of "natural" mutations in this organism to the number produced by artificial irradiation. The intensity of the artificial rays was measured by a "dosimeter" reading in "*r*" units per min., and the number of ions produced during a specific treatment was calculated from this. This result was checked by calculating the intensity of radiation from a tungsten target Coolidge tube by the data of Terrill, and figuring the ionization from this. On the basis of evidence from various observers as to the amount of ionization produced by natural radioactivity in the vicinity of the flies, it was found to be in about the ratio of 1: 200,000 as compared with that to which the animals were subjected in artificial treatments. Yet the ratio of the number of "natural" mutations to those produced artificially in a given time is about 1: 150. Hence it is concluded that the amount of natural radioactivity from the outer environment is far too small to account for the "natural" mutation rate. The radioactivity of substances such as K or U which may occur in or near the organisms was then considered, and it was calculated that the concentrations in which these substances occur in such situations were likewise far too low to produce enough ionization to account for "natural" mutation. In this connection measurements were made of the radioactivity of the bodies of 5000 dead *Drosophila*, and also of that of their food. The possibility remains that the germ cells or the tissues in their immediate vicinity store radioactive substances in far greater concentrations than occur in the organism as a whole. The mature germ cells, however, certainly do not contain any such concentration, since they form so large a proportion of the whole animal that radiation from this source would have been detected in the above mentioned measurements. Also the investigators think it highly improbable that sufficient concentration exists in other tissues. Hence they conclude that some cause or causes other than natural radioactivity must be responsible for the vast majority of "natural" mutations in this animal.—*R. S. McEwen.*

15289. PETROFF, S. G. A comb inhibiting gene. An inhibitor of the development of the Pea and Walnut combs in domestic fowl. *Jour. Heredity* 20(11): 540-542. 1929.—A dominant gene is postulated which inhibits expression of the gene for pea comb (weque in Serebrovsky's nomenclature). Evidence is derived from crosses of pea and walnut with singles which carried the assumed inhibitor. These matings gave an excess of non-pea (aweque) forms.—*S. G. Petroff.*

15290. PICKARD, J. N. A brown-and-black rabbit, a possible case of somatic segregation. *Jour. Heredity* 20(10): 483-484. 1 fig. 1929.—A short-coated black rabbit with areas of both brown hair and long coat is described. The possible cause of this abnormal variation through segregation of the chromosomes is discussed.—*L. M. Dickerson.*

15291. PINCUS, GREGORY. On the temperature characteristics for frequency of breathing movements in inbred strains of mice and in their hybrid offspring. I. *Jour. Gen. Physiol.* 14(4): 421-443. 1931.—Young mice of a selected line of dilute brown exhibit over the range 15-25° C. (body temperature) a relation of frequency of breathing movements to temperature such that when fitted by the Arrhenius equation the data give a value for the constant μ of 24,000 ± calories or, less frequently, 28,000 ±. Young mice of an inbred albino strain show over the range 15-20° C. a value of $\mu = 34{,}000 \pm$, or, less frequently, 14,000 ±, with a critical temperature at about 20° C. and a value of $\mu = 14{,}000 \pm$ above 20° C. The F_1 hybrids of these two strains, and the backcross generations to either parent strain, exhibit only those four values of the temperature characteristic observed in the parent strains and none other. One may therefore speak of the inheritance of the value of the constant μ, but the inheritance shows in this instance no Mendelian behavior. Furthermore, the occurrence (or absence) of a critical temperature at 20° C. appears to be inherited. These experiments indicate the "biological reality" of the temperature characteristics.—*G. Pincus.*

15292. REED, SHELDON C., and GEORGE D. SNELL. Harelip, a new mutation in the house mouse. *Anat. Rec.* 51(1): 43-50. 2 fig. 1931.—This new mutation in mice, probably homologous with harelip in man, consists most commonly of a cleft in the roof of the mouth extending through the upper lip, upper jaw, and hard palate; variations in its expression are frequent. It is usually sublethal. With the exception of one mouse with only a slight harelip which lived to be 3 weeks old, all affected individuals have died within 24 hours after birth because of inability to nurse. Genetically, it behaves as a recessive subject to normal overlaps. A single-principle gene, h^p, and its allelomorph, H^p, are involved; when the gene H^p is present, mice cannot be harelip. When the mutant allelomorph h^p is present in homozygous condition, mice may or may not be harelip, dependent upon the presence or absence of certain modifiers. The existence of modifiers suppressing the development of harelip and cleft palate can be explained by the principle advanced by R. A. Fisher to account for the origin of dominance. All human pedigrees that have come to the writers' attention suggest that harelip in man behaves genetically in a manner closely similar to harelip in mice.—*Authors (courtesy Wistar Bibl. Serv.).*

15293. SEREBROVSKY, A. S., and N. P. DUBININ. X-ray experiments with Drosophila. *Jour. Heredity* 21(6): 259-265. 2 fig. 1930.—Using methods described by Muller, his results were duplicated. The study of lethal mutations showed that among the progeny of certain males mutation occurred very rarely or not at all; while at the same time in other such progenies it occurred very frequently, the unequal distribution being due to chance. Semi-lethals appeared several times. A new visible mutation ("shd"), distinguished by diminished eyes and bristles and splitting of bristles, appeared at the distance 0.2 to the right of white. Several dominant mutations in autosomes were observed; also yellow (1), white (2), miniature (3), furrowed (2), rudimentary (2), forked (8) and fused (1). Four new allelomorphs of scute; $scute^4$, $scute^5$, $scute^6$, and $scute^7$ were obtained and found to be definitely associated with particular types of transgenation.—*L. M. Dickerson.*

15294. SLYE, MAUD. The relation of heredity to cancer occurrence as shown in strain 621. Studies in the incidence and inheritability of spontaneous tumors in mice. *Amer. Jour. Cancer* 15(4): 2675-2726. 1931.—In an entire single strain of mice from a cancerous ♀ and a non-cancerous ♂, bred through 3 generations and consisting of 207 individuals (115 ♀, 92 ♂), 23 were cancerous. The 23 cancers were distributed through the generations thus: parent gen., 1; F_1 (9 individuals), 0; F_2 (36 individuals), 9; F_3 (160 individuals), 13. The types of mating in the 4 generations were: (1) non-cancer × cancer (parent generation and F_2); (2) heterozygous non-cancer × heterozygous non-cancer (F_1, F_2); (3) non-cancer × heterozygous non-cancer (F_2); (4) heterozygous non-cancer × cancer (F_2); (5) non-cancer × non-cancer (F_2); (6) cancer × cancer (F_2). Detailed figures of results show a close approximation to the expectation for cancer as a Mendelian recessive, and the classification of every mouse is confirmed by its progeny.

15295. TIMOFEEFF-RESSOVSKY, H. A. Induced gene-variations in Drosophila funebris. *Jour. Heredity* 21(4): 167-171. 2 fig. 1930.—Males were x-rayed and crossed with virgin non-treated ♀♀. The visible gene-variations, appearing in F_1, F_2 and F_3, and the lethals,

appearing in F_2, from these crossings were recorded. The % of lethals produced by x-rays in *D. funebris* is somewhat lower than in *D. melanogaster*, but at least a part of this difference is due to a much more exact method of detection of lethals in the latter. The visible genovariations produced are typical for *D. funebris*; they affect variable wing- and bristle characters overlapping the wild type.—*H. A. Timofeeff-Ressovsky.*

15296. **TIMOFEEFF-RESSOVSKY, N. W. "Does X-ray treatment produce a genetic after effect?"** *Jour. Heredity* 22(7): 221-223. 2 fig. 1931.—The numbers of lethals and visible x-chromosome genovariations of *Drosophila melanogaster*, arising directly under x-ray treatment, in previously treated (but directly after treatment, mutation-free), and in untreated, cultures were compared. Results from 682 cultures tested for the "direct effect of treatment," 756 cultures tested for the "aftereffect," and 793 untreated control matings show that there is no pronounced "after-effect" of x-ray treatment upon mutability.—*N. W. Timofeeff-Ressovsky.*

15297. **TIMOFEEFF-RESSOVSKY, N. W. Das Genovariieren in verschiedenen Richtungen bei Drosophila melanogaster unter dem Einfluss der Röntgenbestrahlung.** *Naturwiss* 18(20/21): 434-437. 2 fig. 1930.—Males of 6 different stocks carrying in various combinations 10 different sex-linked genes and 10 different genes of the III-chromosome were x-rayed (dosage about 4800r) and mated with ♀♀ from the same culture or, in case of some of the sex-linked genes, crossed with yy-attached-X ♀♀. There were found 12 reverse mutations or about 1 in 18,000 tested allelomorphs; none in about 120,000 controls. At the white eye locus there were found 8 different direct mutations and 5 different reverse mutations. In about 14,000 flies, there were found 9 $W \rightarrow w$ mutations, no $w \rightarrow W$ in 10,000 flies. In about 11,000 w-flies and 14,000 w^e and W-flies, there were found 1 $w \rightarrow w^e$, 1$w^e \rightarrow W$, 2$W \rightarrow w^e$ and 4 $w^e \rightarrow w$. There were also produced the following mutations in opposite directions $S_c \rightleftarrows s_c$, $F \leftrightarrows f$, and $P \leftrightarrows p$. The effect of the treatment upon the gene is not destructive but rather somewhat similar to an intramolecular reconstruction.—*A. H. Hersh.*

15298. **VAN ATTA, ELVENE W., and L. C. VAN ATTA. The spectrum analysis of eye color in Drosophila.** *Amer. Naturalist* 65(699): 382-384. 2 fig. 1931.—Eye color in *D. melanogaster* may be expressed quantitatively in terms of the spectral distribution of light reflected from the eye. Experimental difficulties are not serious and slight changes may be measured.

15299. **VELU, H., et L. BALOZET. Action de la greffe testiculaire sur la descendance.** *Bull. Acad. Vét. France* 4(3): 166-170. 1931.—Two lots of ewes, as nearly as possible equal in weight and age, were bred, one lot to normal Rambouillet-Caru rams and the other to rams which had been used as subjects in a series of testicular graft experiments previously reported, from which it was concluded that the only effect of the grafts was a temporary augmentation of the metabolism and a temporary increase of the body weight. Grafted rams sired 9 lambs and normal rams 11. There were no significant differences between the two groups of lambs.—*L. M. Dickerson.*

15300. **WARREN, D. C. Non-heritable downlessness in chickens.** *Jour. Heredity* 21(9): 408. 1930.—A type of downlessness in Leghorn chicks similar to that described by Serebrovsky (*Ibid.* 20(7): 331-332), though not necessarily identical, was not inherited.—*L. M. Dickerson.*

15301. **WARREN, T. R., and F. W. ATKEN. Inheritance of hernia in a family of Holstein-Freisian cattle.** *Jour. Heredity* 22(11): 345-352. 3 fig. 1931.—Data from 3 herds containing animals related to 1 sire are presented. Of 63 calves observed (42 ♂♂ and 21 ♀♀), 20 ♂♂ and 1 ♀ were herniated. All except 3 ♂♂ and 2 ♀♀ of the 63 calves were related to the sire in question through 1 son, except 1 ♂ calf which descended through a daughter. It is uncertain whether or not the herniated daughter was the result of heredity or other causes. There seems to be little doubt that umbilical hernia in cattle is inherited. Limited data indicate that hernia is inherited in a simple Mendelian fashion and may be due to a pair of autosomes carrying a sex-limited factor for hernia.—*Author's abstract.*

15302. **WLADIMIRSKY, A. P. Über die Vererbung experimentell erzeugter Färbung von Puppen der Kohlmotte Plutella maculipennis. (Vorläufige Mitteilung.)** *Biol. Zentralbl.* 48(12): 739-759. 8 fig. 1928.—Pupal melanic pigmentation depends upon environmental factors (illumination, rather than temp.), apparently followed by a definite after-effect upon the progeny. Selection of phenotypes through 12 successive generations showed shifting of the average, apparently hereditarily fixed; but the genotype involved in experimentally produced phenotypes has sometimes proved to be quite different from that expected. Such invisible genotypical differences were presumably involved in the selection experiments. Hence the assumption of the inheritance of environmental effects is premature so long as no exact analysis of the attendant process of genetic selection is at hand.—*J. H. Gerould (from author's summary).*

15303. **ZAWADOWSKY, M. M. Zebu-Yak hybrids.** *Jour. Heredity* 22(10): 296-313. 17 fig. 1931.—Data are reported on the inheritance of coat color, length of hair, fringe, length of tail hair, hump, horns, and muzzle shape. Body proportions apparently involve many factors. Male F_1 and backcross hybrids were all sterile, the seminal canals having a well developed interstitial tissue but only spermatogonia and cells of the Sertoli type. Only the earliest stages of spermatogenesis were found and no spermatozoa were produced. Secondary sexual characters and traits are well developed. Female F_1 and backcross animals are fecund when crossed with either Zebu or Yak. Heterosis is manifest in the F_1. —*L. M. Dickerson.*

The importance of phenology for agriculture is emphasized.—*A. Vaineikis.*

15308. **WATRY, ALVA, and R. W. LAMSON. Botanic survey of Needles, California. With special reference to the hay fever producing flora.** *Jour. Allergy* 2 (4): 272-281. Map. 3 fig. 1931.—Needles, with an elevation of 467 ft., is situated in the Mojave Valley on the south side of the Colorado River. The total rainfall, usually less than 5 in., is distributed throughout all seasons. The temp. is seldom lower than 40° F. During March-Nov. it may range from a minimum of 50° F. to a maximum of more than 100° F. The soil of this area is quite saline except along the river. There are 3 potential hay fever seasons. Any cases of early spring (Feb.) hay fever would undoubtedly be caused by pollen of *Populus fremontii* and *Salix nigra. Cynodon dactylon* and *Hilaria rigida* begin their pollination in March, thus making a potential late spring season. The real hay fever season is that due to *Atriplex.* Of these *A. lentiformis* and *A. polycarpa* are extremely important; *A. elegans* is of minor importance as are also *Acacia greggii, Prosopis juliflora, P. pubescens, Hymenoclea salsola, Amaranthus palmeri,* and *Franseria dumosa.*—*R. W. Lamson.*

15309. **WRIGHT, F. J. The new nature study.** 287p. 5 pl. 10 fig. Thornton Butterworth: London. 1929. Pr. 5s.—This is a treatise written primarily for the field use of the "rapidly growing army" of phenological observers of the Royal Meteorological Soc. of Great Britain and Ireland. It contains an account of the plants and animals to be observed and a presentation of the methods and results. It is largely concerned with bird migration and seasonal cycles of birds and insects, and with the blooming periods of plants. Floral isophenes and isokairs are plotted on the map of the British Isles. A short history of phenology in Britain and abroad is appended. —*C. A. Kofoid.*

P. Young.*

15315. **BRAUN-BLANQUET, J., und H. WALTER. Zur Ökologie der Mediterranpflanzen. (Untersuchungen**

über den osmotischen Wert.) *Jahrb. Wiss. Bot.* 74(4/5): 697-748. 24 fig. 1931.—In southern France near Montpellier, the most important plant associations are: the *Quercus ilex* forest which is present only in fragments, the *Q. coccifer* scrub, and the *Brachypodium ramosum-Phlomis lychnitis* association. The water relations were examined during a yr., using the osmotic concentration as an indicator. The plants which were examined may be segregated into 7 ecological types according to their behavior and osmotic concentrations. Group I comprises the typical Mediterranean sclerophylls with xeromorphic leaves and very deep roots. Under favorable water conditions the osmotic concentration is relatively high, but shows no increase during the summer drought. The maximum values are reached in the cold winter. These plants are at their northern limit at Montpellier. Group II forms a transition to group III, which is distinguished by specially large fluctuations of the osmotic concentration. Under favorable water conditions the plants of group III show low cell sap concentrations which rise rapidly during the summer drought—a sign that the plants suffer from lack of water. In most of the spp. this is conditioned by poor root systems and is probably aggravated by a checking of transpiration which sets in only very late. Most of the sp. possess xeromorphic leaves, but are not typical sclerophylls. *Viburnum tinus* has good roots, but possesses mesomorphic leaves. Group IV comprises the coriaceous leaved shape plants. These possess xeromorphic leaves, have relatively good root systems, and grow under less extreme conditions in shady habitats; hence they do not suffer from lack of water even during the dry season. The osmotic concentrations are relatively low, showing an increase only in the winter. For the time being only *Euphorbia characias* is placed in Group V—a plant which grows frequently in very sunny habitats, but which possesses a very even water balance. Plants which possess aerial organs only in the spring or in the fall and winter, i.e., when the water conditions are favorable, are placed in Group VI. They have meso- or hygromorphic leaves and low osmotic concentrations. The succulents, of which only *Sedum altissimum* was examined, were put in Group VII. They have the lowest osmotic concentrations, are distinguished by their low transpiration intensity, and survive the drought by very economically utilizing the water which is stored in the leaves.—*Author's summary (transl. by T. M. Plitt).*

15316. BUJOREAN, GHEORGHE. Contribuţiuni la cunoaşterea succesiunii şi intovarăşirii plantelor. Lucrare di fitosiciologie experimentala. [Plant succession and plant associations. Experimental plant sociology.] [English summary.] *Bul. Grad. Bot. Muz. Bot. Univ. Cluj* 10(1/4): 1-183. 23 pl. 1930.

15317. CAIN, STANLEY A. Certain floristic affinities of the trees and shrubs of the Great Smoky Mountains and vicinity. *Butler Univ. Bot. Studies* 1(paper 9): 129-150. 2 maps. 1930.—The spp. in this southern Appalachian region are arranged according to their main geographical distributions (intraneous, extraneous, southern, northern, Canadian transcontinental, etc.), and these geographic classes are considered in respect to their location in the Great Smoky Mts. Intraneous spp., i.e., those which, in the Smoky Mts., are well within their ranges, constitute 69% of the 248 woody sp. considered. The remaining 31% are to be considered extraneous, i.e., they are northern or southern extensions or disjuncts into the Smoky Mts. and have their main distributions elsewhere. 22% of the flora is southern Appalachian, while 12% of that group is essentially endemic to the Unaka Range, of which the Great Smoky Mts. constitute the major portion. Of the extraneous spp., 26% are southern extensions of northern spp., whereas only 5% are southern; a situation which is clearly related to the mountainous conditions. In the mountains the northern elements appear in increasing importance with increasing altitude until the climax is reached in the spruce-fir zone, with 59% of its woody flora made up of northern spp.—*Author's summary.*

15318. CAIN, STANLEY A. An ecological study of the heath balds of the Great Smoky Mountains. *Butler Univ. Bot. Studies* 1(paper 13): 177-208. 2 pl., 1 fig. 1930.—A type of vegetation in the U. S. A., apparently peculiar to the Southern Appalachian Mts. is called "heath bald" because (a) the dominant shrub flora is largely composed of sp. belonging to the Ericaceae, and (b) trees are absent from well-developed examples of this association. The heath balds occur as restricted areas mainly on the windward sides of upper slopes and peaks at 4,000-6,500 ft., being more frequent in the subalpine zone. They have a fairly constant physiognomy throughout this range, despite a considerable change in sp. content, and can be described briefly as broad-sclerophyll scrub with a considerable content of evergreen sp. These facts are brought out by tables showing (a) relation of the flora of these island-like areas to the contiguous forests, (b) change in sp. content with change in altitude, (c) an analysis of the flora according to Raunkiaer's life-form classes, and (d) leaf-size classes. Initiation, maintenance and distribution of the heath balds is considered on a basis of climatic, edaphic, and catastrophic factors. It is concluded that they are post-climax, and consequently are derived from the contiguous forest associations as the result of the interaction of a number of various factors. With cool and humid climatic conditions and evergreen vegetation, there is a decided development of edaphic conditions (high acidity, peat formation, and podsolization), which progressively favor heath bald sp. In many places it is apparent that the elimination of the trees would permit the undershrubs to develop a closed cover, which they are apparently quite capable of maintaining, in most instances, against the encroachment of trees. The biological equipment of the ericads is such as to favor them in competition with other plants under these rather extreme edaphic and climatic conditions, yet their occupancy of these areas is due more to their tolerance of the conditions, since their vitality is greater under the protection of trees.—*Author's summary.*

15319. CAIN, STANLEY A. Ecological studies of the vegetation of the Great Smoky Mountains of North Carolina and Tennessee. I. Soil reaction and plant distribution. *Bot. Gaz.* 91(1): 22-41. 6 fig. 1931.—Soil samples (289), taken at the surface and 6 in. depth, from 11 forest types scattered over an altitudinal range of 1,000-6,600 ft., were tested for pH. The total range was pH 2.8-8.2. Each forest type showed considerable range in pH; contiguous communities overlapped in range but were separable on averages derived from 10 to 60 tests each. When arranged in altitudinal sequence, the forest types were progressively more acid with increasing altitude. This is also true for different stands of the same forest type. Triplicate tests on each soil sample averaged about 0.1 pH deviation from the mean; this demonstrates that 1 test per sample is sufficient, but more numerous samples are of greater value. Emphasis is placed on broad sclerophyll scrub communities, post climax to the spruce-fir, at high elevations because of their extreme acidity, surface soils averaging pH 3.2 and 3.6, while samples at 6 in. depths averaged 3.8 and 4.0 at 6,600 and 5,000 ft., respectively. This community, dominated by ericaceous sp. and accompanied by extensive upland peat formation is here described for the first time. The general problem of high soil acidity is discussed in relation to climatic, edaphic, and biotic factors, coordinated largely with high altitude.—*S. A. Cain.*

15320. CARDOT, J. Le peuplement bryologique des îles britanniques. [In: Contrib. à l'étude peuplement des îles britanniques; Mem. Soc. Biogéogr. 3.] P. 151-161. Paul Lechevalier: Paris, 1930.—The moss flora of the British Isles and that of western Europe evidently have a common origin; moreover, it is certain that, only

after the disappearance of the last glaciers at the end of the Quaternary, the Mediterranean element was introduced into the Isles, aided chiefly by winds. But this invasion was also aided by migratory birds, which may also explain the origin of several types of tropical mosses. These factors, however, do not explain the presence of mosses from western Europe and the Mediterranean on the Pacific Coast of N. America when they are absent from the Atlantic Coast. Perhaps one can consider these forms as relics of a temperate flora which, once widespread in all the northern hemisphere, disappeared in the eastern part of America as a result of a cooling of the local climate, perhaps owing to a change in the ocean currents.—*From author's conclusions (transl.)*.

15321. CHEVALIER, AUG. Le peuplement végétal des montagnes de l'Ouest africain. [In: *Peuplement des Hautes Montagnes.*] *Mém. Soc. Biogéogr.* [*Paris*] 2: 221-229. 1928.—Previous work on the vegetation of the West African mts. is briefly reviewed. Lists are presented of 20 European sp. which are found on these mts. or are represented there by closely related forms; of others that are common to the Cameroon Mts. and Abyssinia or So. Africa; of several endemic genera; and of certain forms of the East African mts. that are lacking in the West African mts. It is suggested that the invasion of the mountain sp. took place during the Glacial period. There may have been transportation of spores by the wind and of seed by birds to spots made bare by volcanic eruptions.

15322. CONZATTI, C. Las regiones botanico-geograficas del Estado de Oaxaca. *Proc. Internat. Congr. Plant Sci., Ithaca, N. Y. 1926* 1: 525-539. Map. 1929.—Oaxaca occupies approximately 1/22 of Mexico, between 15° 43′ and 18° 25′ N. latitude. Its 92,000 sq. km. of surface can be divided into 3 nearly equal regions,—low land with a tropical climate (0-1200 m.), valleys and plateaus with a temperate climate (1,200-2,000 m.), and the mountains (2,000-3,400 m.) with a cool climate. On the north or Gulf slope of the mountains, there is a moister climate and more luxuriant vegetation than on the southern, Pacific, side. On the Pacific side, oaks and conifers occur at 650-1,000 m., while on the Gulf side they are only found at 1,200-1,850 m. Over 150 families of plants are represented. Some are distributed through all the regions (*Polypodiaceae, Gramineae,* and *Leguminosae*); others have representatives in most of the zones (*Anacardiaceae, Malpighiaceae, Orchidaceae,* and *Borraginaceae*); a few are represented in only 1 zone (*Rizophoraceae, Fouquieraceae,* and *Valerianaceae*). Region *A,* sub-region (1) extends along the Pacific coast with an elevation under 100 m. Among the characteristic plants are: (a) on submerged rocks, various red and brown algae; (b) in the lagoons and bays, the mangrove, *Rhizophora mangle,* and *Acrostichum excelsum;* (c) on the beaches, such grasses as *Anthephora elegans, Bouteloua aristoides,* and *Jouvea straminea,* with *Okenia hypogaea;* (d) near the shore, *Hibiscus tiliaceaus;* and (e) on the low hills, various Anonaceae, 1 cactus, and *Espejoa mexicana.* Sub-region (2), on the coast and low valleys, is dry Oct.-May, humid June-Sept. This is the warm dry region, arid in general appearance, but very rich in number of sp. Large trees with fine wood, spiny leguminous shrubs, and cacti are numerous. In the south-western part of the region, cotton and coffee are grown; in the south-east, anil is one of the principal crops. Among the native plants are *Hymenaea coubaril, Toluifera pereirae, Haematoxylon brasiletto, Rourea glabra, Diospyros conzattii,* and *Attalea cohune.* The broad valleys on the gulf slope are warm and dry with an elevation of 550-1,200 m. The vegetation is quite distinct from that on the south side. Sugar cane and rice are cultivated. Cacti of several sp. are abundant, among them *Escoutria chiotilla, Myrtillocactus geometrizans,* and *Pachycereus columna. Elaphrium aloexylon, Ceiba aesculifolia,* and *Achras sapota* also occur here. Sub-region (3) is very moist with dense vegetation so hard to penetrate that it has been little explored. It is rich in palms and in valuable hard woods, with many sp. of ferns. Probably this sub-region should be divided into 2 or more sub-divisions. Where the forest has been cleared, cacao, sugar, coffee, tobacco, bananas, and rubber are cultivated. *Castilloa elastica, Sphagnum meridense, Alsophila schiedeana, Sobralia macrantha,* and *Dictyanthus tigrinus* are found. Region *B,* with a mean annual temp. of 19-20° in the lower parts, and 15-16° C. in the higher, is extensive and hard to characterize. The sub-region (1) occupies most of the center of the state at 16°-17° N. latitude. Sugar cane, wheat, and corn are cultivated. The numerous native plants belong to more than 70 families. The leguminous genus *Conzattia* and *Hicoria tetraptera* are fairly common. Sub-region (2) continues the former to 2,000 m. and extends 1° further N. Some parts are very moist, others are dry except in the rainy season. Sugar and coffee are cultivated in the eastern part, wheat in the western, and corn in all. The numerous plants represent 30 different families. *Rhus toxicodendron, Euphorbia fulva, Liquidambar styraciflua,* and numerous orchids occur. Region *C,* sub-region (1) begins at about 2,000 m. and extends up to about 3,000 m. Among hundreds of plants that might be mentioned are *Aporocactus conzatti, Drimys winteri, Quercus conzatti, Gaultheria acuminata, Abies religiosa, Pinus oocarpa,* and *Juniperus flaccida.* Sub-region (2) at 3,000-3,400 m. has a large number of sp., differing on the various mountains. Among the characteristic plants are *Callitriche verna, Lomaria procera, Cestrum nitidum, Gentiana adsurgens, Epidendrum elegans, Polypodium conzattii, Viola pringlei, Arctostaphylos conzattii, Abelia floribunda, Dahlia variabilis, Aplopappus stolonifera, Deyeuxia triflora,* and *Fourcroea longeva.* A few of the plants of the region have come from the north and some from the southeast, but a very large number are endemic.—*G. T. Hastings.*

15323. COSTELLO, DAVID F. Comparative study of river bluff succession on the Iowa and Nebraska sides of the Missouri River. *Bot. Gaz.* 91(3): 295-307. 7 fig. 1931.—East- and west-facing bluffs are compared with respect to number of plant individuals, variety of sp., and area occupied by the linden-ironwood climax. The effect of prevailing winds in producing treeless west-facing bluffs is discussed.—*D. F. Costello.*

15324. DAUBENMIRE, REXFORD F. The acid ranges of some spring-flowering herbs with reference to variations in flora color. *Butler Univ. Bot. Studies* 2(paper 2): 25-28. 1931.—Local variants in flower color were not correlated with differences in soil pH. These comprise: in *Phlox divaricata,* from pink to blue and white; in *P. bifida,* pink, lavender, blue and white; in *Tradescantia brevicaulis,* pink, purple, and blue; in *Dodecatheon meadia* pink and white; in *Delphinium tricorne,* blue, blue and white, and white; and in *Hepatica acutiloba* and *Lupinus perennis,* blue and white.

15325. DAUBENMIRE, REXFORD F. Factors favoring the persistence of a relic association of eastern hemlock in Indiana. *Butler Univ. Bot. Studies* 2(paper 3): 29-32. 1931.—A comparison of several vital ecological factors in a relic colony of hemlock and in its surrounding and more indigenous climax of beech-maple, indicates that whenever these factors differ (in soil moisture, soil temp., and soil acidity), the most favorable extreme is found in the hemlock environment. Air temp. and evaporation studies indicate no appreciable difference between the environments of the widespread climax and the relic edaphic climax. In view of the factors considered, a particular site, which by means of its topography is conducive to extreme drainage and consequently presents a dry soil for plant occupation, is the only adverse condition which the hemlock may make use of in getting established. Once established, a secondary group of conditions arises, through the presence of the hemlock itself, which tends to inhibit the seedlings of competing plants and thus to secure the permanency of this relic association.—*Author's summary.*

15326. DOAK, B. W. Tidal-flat and salt-marsh studies

in Nelson Haven. Part II. The soil chemistry of the Nelson mud-flat. *New Zealand Jour. Sci. & Tech.* 13 (1): 1-11. 2 pl. 1931.—Succession on the naturally "reclaimed" soils is as follows: a scattered *Salicornia* association, on areas covered with sea-water during spring tides; a *Juncus maritimus-Leptocarpus* sp. association, which entraps silt actively, and builds up a bank of soil; on poorly drained, entrapped, very fine silt, on the lee of the *Juncus* bank, *Salicornia* forms a dense association, in which algae appear; a high-marsh association, with *Salicornia* and *Lepturus*, which becomes invaded by *Selliera* sp., forming a *Salicornia-Selliera* association; a manuka association, comprising also stag's-horn, grasses, trefoil, etc., on the peat formed by the last; and finally, a climax association of grasses (*Poa pratensis*, etc.) and white clover. On areas artificially reclaimed (by dykes) the succession is: a pure *Salicornia* association; a *Salicornia*-plantain association; a grass-plantain association; and, finally, a rye grass-white clover association. Soil profiles and soil textures, soil water content, and chemical composition are given for each of these.

15327. ERDTMAN, G. Pollen-statistics: a new research method in paleo-ecology. *Science* 73 (1893): 399-401. 1 fig. 1931.—A suggested method for obtaining and studying fossil pollen grains in peats and sediments is presented. The relative frequency numbers of the pollen-sp. found in a sample taken at regular intervals in each peat-boring constitutes the pollen spectrum. On the basis of a series of pollen-spectra, a pollen-diagram is constructed, using the depth of the peat as ordinates and the pollen % as abscissae. This gives a visual representation of the composition of the pollen flora during the formation of the bog, with certain enumerated exceptions.—*S. S. Potbury.*

15328. FIRBAS, FRANZ. Über die Bedeutung des thermischen Verhaltens der Laubstreu für die Frühjahrsvegetation des sommergrünen Laubwaldes. [Thermic value of leaf-litter for early spring vegetation of deciduous forests.] *Beih. Bot. Centralbl. Abt. 2.* 44 (2): 179-198. 1927.

15329. FIRBAS, FRANZ, (unter Mitwirkung von HANS SIGMOND). Vegetationsstudien auf dem Donnersberge im Böhmischen Mittelgebirge. *Naturwiss. Zeitschr. Lotos* 76 (4/5): 113-172. 4 pl., 6 fig. 1928.—The Donnersberg (or Milleschauer) near Teplitz reaches the greatest altitude (835 m.) of the Bohemian Middle Mts. It consists of volcanic phonolite. Steppe vegetation is excluded by the precipitation (about 600 mm.). The forest is the climax and occupies all ground except rocks and stony hillsides. The climax associations on stony hillsides are divided into those characterized by: *Quercus sessiliflora-Deschampsia flexuosa; Tilia cordata-Poa nemoralis; T. cordata-Calamagrostis arundinacea; Q. sessiliflora-Melica uniflora;* and *Picea excelsa-C. arundinacea-Oxalis acetosella.* The leading forest-types are divided into oak slope forests, beach forests, and oak forests rich in *Melampyrum.* The high summits are distinguished by high limits of thermophilous plants and consortia, and by stations of some eurasiatic-subarctic and alpine sp. The temp. is like that of the Bohemian border mountains, but the precipitation increases much slower with altitude. The climate of the high situations is dry-cool. The soil is generally acid, pH 4.7-3.—*Max Onno.*

15330. GODWIN, H. The "sedge" and "litter" of Wicken Fen. *Jour. Ecol.* 17: 148-160. 4 fig. 1929.—This fen is one of the last relics of the fen-lands of eastern England. Its vegetation is of the "Flachmoor" type dominated by sedges, rushes, and grasses; *Sphagnum* and the Ericaceae are absent and the peat is alkaline. Among the many plant communities covering its surface in a complex mosaic, those designated "sedge" and "litter" are most conspicuous. The former consists of an almost pure stand of *Cladium mariscus,* an evergreen slow growing plant cut once in 4 yrs. for thatching material. "Litter" is a mixed stand of *Molina coerulea, Juncus obtusiflorus, Carex panicea,* and other plants cut about once in 2 yrs. and used as litter or in some cases for fodder. It is concluded that the present complex of fen vegetation is due to the presence of all stages of a primary hydrarch succession, of various stages of 2 deflected successions produced by heavy and light cuttings respectively, and, in addition, various true secondary succession stages following the removal of shrubs. The fen is therefore a relic of the old English fenland which displays the reaction of plant communities to different aspects of an ancient mode of agriculture.—*G. D. Fuller.*

15331. HENRY, LEROY K. Ecological observations upon the flora of Wading River, Long Island, New York. *Proc. Pennsylvania Acad. Sci.* 4 (6): 60-65. 1930.—Remarks on geology, physiography, and climate are followed by brief descriptions of 5 plant communities: pine barrens, ponds and bogs, deciduous forest, beach, and roadsides and abandoned fields. There is a tendency for the vegetation of the deciduous forest to invade the pine-barren region. Some sp. are merely migrants which disappear after the first season, while others complete ecesis, i.e., adjustment of a plant to a new home, by germinating, growing, and reproducing. The roadsides and abandoned fields may serve as a stepping stone in this migration. The vegetation of the ponds clearly indicates the advance of plant successions and the great work of plants in converting ponds into swamps and the latter into dry land. These pine-barrens seem to be an association of the deciduous forest held in check by edaphic factors, as shown by the ecesis of oaks and locusts after the former's destruction by fires.—*From author's summary.*

15332. HESMER, H. Pollenanalysen eines glazialen Torfes bei Marsberg i. Westf. Beitrag zur diluvialen Waldgeschichte. *Ber. Deutsch. Bot. Ges.* 47 (2): 110-118. 4 fig. 1929.—In this peat deposit are found pollens of *Pinus, Picea, Tilia, Carpinus, Betula, Alnus, Corylus,* in from 0 to 100%, depending on the depth below the surface. The lower beds, containing a fairly large % of wood pollen, were formed in the subarctic climate of the interglacial period. The upper part, which is richer in non-wood pollen, enjoyed a warmer and more genial climate.—*W. Berry.*

15333. HEUMANN, MARTIN, und HUBERT WINKLER. Charakterpflanzen aus Südwestafrika. *Vegetationsbilder* 21 (8): pl. 43-48. 1931.—Illustrations and brief descriptions are given of *Salicornia fruticosa, S. herbacea, Gomphocarpus fruticosus, Euphorbia monteiri, Stapelia* sp., *Harpagophytum procumbens, Drimiopsis* sp., *Tribulus terrestris, T. zeyheri,* and *Buphane disticha.*—*G. D. Fuller.*

15334. HUBER, BRUNO. Die Trockenanpassungen in der Wipfelregion der Bäume und ihre Bedeutung für das Xerophytenproblem. *Jour. Ecol.* 19: 283-291. 1931.—The foliage of trees at different heights was examined to determine whether there existed a decrease in transpiration corresponding to an increased water deficit. There was a greater decrease in transpiration with increased height in mesophytic (shade tolerant) trees than in more resistant trees. Thus the greatest decrease was found in *Sequoia gigantea, Fagus, Tilia,* and *Picea;* a less decrease in *Acer* and *Quercus;* and the least decrease in *Fraxinus, Larix,* and *Pinus.* Whereas *Sequoia* showed no structural differences between the lower and upper leaves, in *Quercus* there were distinct transitions to xeromorphic structures: smaller, thicker, and more lobed leaves, with a more wavy surface and irregularly oriented toward the light ("sun leaves"). In *Q. pedunculata* there was no decrease in transpiration with increased height, in fact usually an increase. The transpiration per unit area was greater than in the lower leaves, but the transpiration per unit wt. was the same. In 1 experiment both sun twigs and shade twigs were placed first in a moist chamber with the cut surfaces in water, and then in air. The shade twigs exhibited greatly increased transpiration whereas the sun leaves showed little change. It is concluded that under optimum conditions shade leaves (mesomorphs generally) transpire more than

sun leaves (xeromorphs). In another experiment both types of cut twigs were left to dry in the air. The shade leaves checked their transpiration decisively, especially during the 1st hr., but it took the sun leaves 2 days longer to become air dry. It is hence concluded that shade leaves check their transpiration more rapidly than sun leaves by closing their stomata early in case of water deficit; but the greater cuticular protection (and probably physiological and other factors) determine the better resistance of sun leaves to prolonged drought. The term "sun plant type" is suggested for plants which exhibit adaptations to drought similar to those of the sun leaves. This term implies the existence of other types of drought adaptations, e.g., the deviating succulent type.—*T. M. Plitt.*

15335. **HUMBERT, HENRI. Végétation des hautes montagnes de Madagascar.** [In: *Peuplement des Hautes Montagnes.*] *Mém. Soc. Biogéogr.* [*Paris*] 2: 195-220. 1928.—There are 3 principal massifs in Madagascar, with maximum altitudes of 2644-2880 m. Repeated fires have had a disastrous effect upon the vegetation, especially the endemic sp. A burnt forest is generally replaced first by a shrubby growth, dominated by Ericaceae and Compositae. When this growth is burned in turn, it is replaced by sclerophyllous Gramineae, the final type of vegetation thus being a prairie. The mountain flora of phanerogams is composed almost entirely of endemic sp. or even endemic genera. There are also numerous non-endemic genera, represented in Madagascar, however, only by endemic sp.; some of these genera occur on the mts. of East Africa, and some are more widely distributed in various parts of the world. The mountain flora of Madagascar has definite affinities not only with sp. of eastern and tropical Africa, but also with some of Australasia, India, So. America, and the Mediterranean countries. Many endemic sp. have a clearly relic character, and their affinities with foreign sp. indicate a foreign derivation. This double character of a large part of the mountain flora implies ancient land connections. The high % of endemism is evidence of the antiquity of the separation, which was certainly pre-Quaternary. Paleontological and zoogeographical data, supplemented by phytogeographical data, indicate that connections between Australasia, India, and Madagascar persisted till toward the end of the Cretaceous, and those between Africa and Brazil to the early Tertiary, while connections between Africa and Madagascar were reestablished in the Eocene, Oligocene, and Miocene. There is most evidence of connections between Africa and Madagascar. Especially during the Tertiary large earth movements created conditions favorable to the differentiation of endemic forms.—*From author's summary.*

15336. **ISSLER, E. Les associations végétales des Vosges Méridionales et de la plaine Rhénane avoisinante. II. Les Garides et les Landes.** *Bull. Soc. Hist. Nat. Colmar* 21: 47-158. 1929.—The "garides" are represented by 16 100 sq. m. quadrats in various parts of the Xero-Brometum, in which *Bromus erectus, Hippocrepis comosa, Teucrium chamaedrys, Stachys rectus,* and *Asperula cynanchica* are the most abundant sp., together with a *Festuca ovina* sub-association. There is an exceedingly rich bryophyte flora. The "landes" are represented by 2 principal associations: *Festuca rubra-Genistella sagittalis* and *Nardus-Vaccinium.* The former association is rich in *Agrostis vulgaris, Anthoxanthum odoratum, Deschampsia flexuosa, Thymus serpyllum ovatus, Campanula rotundifolia,* etc.; the latter in *Leontodon pyrenaicus, Galium saxatile, D. flexuosa, Agrostis vulgaris, Potentilla erecta,* etc. Successions culminating in *Quercus sessilis-Carpinus betulus* begin as nano-lichens and nano-bryophytes on rocks; as *Agropyrum repens* or *Poa pratensis angustifolia* in old fields; and as nano-bryophytes, nano-lichens, *Sedum, Teuerium,* etc., on sands and gravels. A succession passing into *Abies alba* begins as a *Festuca-Genista* association, passing through a *Pteridium* stage and then through either *Betula verrucosa* or *Corylus avellana.* A transition type of succession passes through *Juniperus* to fir. The "superieur" succession passes through *Sorbus* toward *Fagus.*—*Frank Thone.*

15337. **[IVANOV, L. A.] ИВАНОВ, Л. А. Солнечная радиация как экологический фактор. [Solar radiation as an ecological factor.]** Труды по Прикладной Ботанике, Генетике и Селекции (*Bull. Appl. Bot., Gen. & Plant Breed.*) 18(5): 345-368. 1928.—The caloric effect of the tropical sun is not greater than that of the sun in the North, and the maximum intensity of the solar rays varies but little on the earth's surface, due largely to differences in absolute humidity in the atmosphere. The clearer the sky, the weaker is the solar radiation. With an increase of water vapor, the radiation also increases, and particularly with the appearance of clouds (not rain). In such cases, the intensity may reach 0.3-0.6 gm. cal. per min. per sq. cm. which is about $\frac{1}{4}$-$\frac{1}{2}$ of the intensity of the noon sun. It is concluded that in addition to the intensity of solar radiation, the biologist must also know the activity of the solar rays illuminating the plant, and their physiological importance.—*L. J. Pessin.*

15338. **JONES, EDWARD N. The morphology and biology of Ceratophyllum demersum.** *Univ. Iowa Studies, Nat. Hist.* 13(3): 11-46. Map, 4 pl., 4 fig. 1931.—It is proposed to reduce the number of recognized sp. to 2: *C. demersum* and *C. submersum.* Long association with water has modified stem structure in several ways: caused lack of mechanical cells in either xylem or phloem; metamorphosed sieve-tubes occasionally into air spaces; and transformed some xylem vessels into parenchyma cells. Air space development is schizogenous. Form of plant was modified from sturdy to slender habit by transplanting from cool, clear, lake-water to warm, stagnant, pond water. Stamens dehisce while still attached to receptacle as well as after separation from it. The latter is the only method recognized previously. The plant depends more upon vegetative propagation, including fragmentation, than upon reproduction by seed. The usual winter vegetative dormancy was broken and mid-summer luxuriance induced during winter by means of artificial light and temp. supplied by electric-light bulbs immersed in an aquarium. The results of an extensive survey of the distribution of *Ceratophyllum* in West Okoboji Lake, Iowa, include: total area 434 acres, equivalent to 11% of surface area of lake; mean depth of zone supporting the plant, 4.01 m.; mean distance from shore 111.11 m., average width of zone, 56.23 m.; and average depth range from inner to outer margin, 1.74 m. The bays constitute a more favorable habitat than the open portions of the lake. The plant has its chief value as a biotic factor in its oxygenation of the water and as a shelter and indirect source of food for fish.—*E. N. Jones.*

15339. **KELLER, PAUL. Pollenanalytische Untersuchungen an einigen Mooren des St. Gallischen Rheintales. [Pollen analyses in connection with some moors of the St. Gall Rhine Valley region.]** *Jahrb. St. Gallischen Naturwiss. Ges.* 64: 82-95. 1928(1929).

15340. **KERNER, A. Das Pflanzenleben der Donauländer.** 2nd ed. [reimpression], with additions and 24 plates: edited by **F. VIERHAPPER.** xvi + 452p. Universitäts-Verlag Wagner: Innsbruck, 1929.—This edition is a reimpression of the original which appeared in 1863, in which the comments of the editor are presented as an appendix on pp. 349-452. These notes are referred to the proper pages of the original text. They comprise summaries of the more general literature on the subject of plant sociology as well as on the special problems of the territory concerned. Kerner's "formations" are considered to be equivalent to the present concept of "association." The plant names used are brought up to date in a separate list according to the nomenclature of the regional manuals. The bibliography lists about 150 titles. The 24 plates are either Kerner's own drawings (selected from his other publications) or photographs of characteristic formations or landscapes.—*T. Just.*

15341. **KLIKA, JAROMÍR. Contribution à l'étude géobotanique de Velkâ Hora près de Karlstein.** *Preslia Vest-*

nik Československé Bot. Spolec. (Rept. Czechoslovak. Bot. Soc. Prague) 1928(6): 31-34. 1928.—Results of soil analyses of Velká Hora near Karlstein (near Prague) show that the soils are moderately acid and vary considerably, but are not important in determining plant distribution. Climatic factors seem of greatest importance in distribution of plants of steppes and semi-steppes.—*J. Klika.*

15342. **KOBENDZA, R. Bielany pod względem botanicznym.** [The flora of Bielany.] [French summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest. Ann.)* 22: 299-342. 9 fig. 1929.—This forest region near Warsaw descends on one side from a high diluvial terrace of the Wisla River to a 2nd terrace of sandy composition, and then down to the 1st terrace which is inundated at flood periods. In the forest, 6 associations can be distinguished: Alnetum, Alneto-Quercetum, Carpineto-Quercetum, Querceto-Pinetum, Quercetum, and Pinetum. The first 2 are the best preserved; the others contain few characteristic sp. owing to the presence of man. The Wisla influences the flora very much; numerous sp. grow along its banks during the floods and some are almost limited to the lowest terrace, such as *Aristolochia clematitis, Petasites spurius, Senecio fluviatilis, Solidago canadensis,* etc. Though the flora of Bielany is constantly ravaged, some of the rarest sp. around Warsaw are well preserved here in inaccessible places, e.g., *Luzula multiflora, Hypericum montanum,* and *Hieracium pratense.* Formerly Bielany was a drill ground for Russian soldiers and now many visitors go there for amusement; these facts have contributed to the introduction of sp. unknown elsewhere in these parts, e.g., *Poa bulbosa* v. *vivipara, Dracocephalum thymiflora,* and *Salvia verticillata.*—*Author's summary (transl.).*

15343. **KOZO-POLJANSKI, B. M. Xerotherme Relikten am Flusse Tichaja Ssosna (Südrussland).** *Vegetationsbilder* 22(2): 1-4. pl. 7-12. 1931.—This includes steppe vegetation on limestone slopes and limestone hilltops with *Matthiola fragrans* and *Thymus cretaceus,* together with more detailed photographs of *Hyssopus cretaceus, Asperula cretacea, Thymus cretaceus, Scrophularia cretacea, Festuca cretacea,* and *Artemisia hololeuca.* —*G. D. Fuller.*

15344. **[KRASOVSKAĬA, I. V.] КРАСОВСКАЯ, И. В. Обзор работ по морфологии и физиологии корней.** [Review of work on morphology and physiology of roots.] Труды по Прикладной Ботанике, Генетике и Селекции (*Bull. Appl. Bot. Gen. & Plant-Breed.*) 18(5): 3-121. 1928.—The structure of roots and their physiological functions are fully discussed, and the literature on roots in general is critically reviewed.—*L. J. Pessin.*

15345. **KRAUSE, K. Gehölze im inneren Kleinasien.** *Naturwiss.* 16(5): 73-75. 1928.—The interior of Asia Minor consists essentially of a plateau bounded by mountains on the north, south, and east, descending gradually to the seacoast on the west. The annual rainfall is generally less than 10 in. and falls mostly in the spring. The vegetation of the plateau plain is of a steppe character, woody growth being limited mainly to stream banks. The commonest tree is the Lombardy poplar (*Populus italica*). Other trees are *Ulmus campestris, Salix alba,* and *S. babylonica.* These associate along the water courses with sp. of *Tamarix, Eleagnus hortensis, Platanus orientalis* (which reaches a large size), *Fraxinus oxycarpa, Pirus eleagnifolia,* and several sp. of *Quercus* and *Crataegus.* The steppe formation extends up the mountains to 1400-1600 m., beyond which a broken forest zone, the remnant of a much more extensive formation, extends upward to 1900-2000 m. In this zone, conifers give character to the vegetation, *Pinus laricio* and various *Juniperus* spp. being common. There are also several oaks and maples. Among the shrubs appear sp. of *Daphne, Rhamnus,* and *Cistus.* Only 2 introduced trees appear to be adapted to the climate of this region, *Ailanthus glandulosa* and *Robinia pseudacacia.*—*F. S. Baker.*

15346. **KRYLOV, P. N. Die Abgrenzung von Steppen- und Waldsteppenzonen auf floristisch-statistischer Grundlage.** [In: *Handbuch der biologischen Arbeitsmethoden.* Abt. XI. Chemische, physikalische und physikalisch-chemische Methoden zur Untersuchung des Bodens und der Pflanze. Teil 6, Heft 1. Lief. 335.] 129-136. 1930.—By means of the statistical quadrant method the steppes of western Siberia are analyzed. The ratio of the number of sp. each plant formation to the sum total of the sp. characteristic of the area is used as an index. The vegetation may be divided on the basis of these ratios mainly into 2 phytogeographic areas: the forest and the steppe. A 3rd area is the desert steppe. The transition between these and also between the subdivisions is a very gradual one. The forest is subdivided into the peat and conifer zone and the peat and birch zone. The steppe is divided into the forest steppe zone and the open steppe zone. The former is still further differentiated into (a) the closed grass subzone, (b) the herb grass subzone, and (c) the *Stipa-Festuca* grass subzone. —*T. M. Plitt.*

15352. **LIBBERT, WILHELM. Die Vegetation des Fallsteingebietes.** *Beih. Jahresber. Naturhist. Ges. Hannover* 2. 1-66. 1930.—The vegetation of an area of 150 sq. km. in central Germany is described in detail under 11 "Verbands" or "Associationsverbands," with the oak-hornbeam regarded as the climax.—*O. A. Stevens.*

15353. **LINDQUIST, BERTIL. Den skandinaviska bokskogens biologi.** [Ecology of Scandinavian beech forests.] [With English summary.] *Skogsvårdsför. Tidskr.* 29(3): 179-532. Map. 74 fig. 1931.—Mapping of the areas of *Fagus silvatica* forest was done by sketching from an airplane on base maps during the period of bud-opening, May 5-20, when beech could be distinguished from oak and other trees even at a great height. Intensive field studies on the ground showed that on very acid and moderately acid mull soils having intensive nitrification, meadow plants invaded the forest; while on less strongly acid, or basic mulls abundant ground flora was present even with 1-2% light intensity. Under the prevalent beech thinning practice, the increased light has apparently caused an increase of the abundance of *Oxalis acetosella.* Where nitrification was very active, *Oxalis* failed to survive or reproduce at intensities below ½% of full light. The abundance of *Anemone nemorosa* and *Geranium robertianum* was also dependent on light intensity. Where acidity was high, as in young stands, these plants were absent, even with adequate light. Where thinnings had been neglected and on acid mulls, a degeneration of ground vegetation occurred. The influence of nitrification in causing

conditions favorable for an increase of meadow herbs at the expense of heath vegetation was intimately connected with the prevalence of mycorhiza. Thus *Deschampsia flexuosa* disappeared when nitrification set in, owing to its depressing influence on the development of mycorhiza on this plant. Conversely, *Dryopteris linnaeana* colonized beech forests at the stage where nitrification had begun. Thus communities can be classified with respect to nitrification as (1) synusiae indifferent to nitrates, composed chiefly of grasses and sedges; (2) facultative nitratophilous synusiae, which may be independent of nitrification under conditions favorable to their reproduction; and (3) obligate nitratophilous synusiae, occurring on soils with pH 4.5-5.5, with strong nitrification. These synusiae are composed of *Geranium robertianum, Impatiens noli tangere, Stellaria glochidosperma,* and many others. Acidity as such seems to be of less importance than mycorhiza in limiting the distribution of heath communities. In the herbaceous meadow type of beech vegetation it is possible to distinguish groups differing in relation to acidity: (1) synusiae indifferent to acidity, *Acer, Fraxinus, Rubus, Deschampsia, Anemone, Oxalis,* etc. socions; (2) acidophilous synusiae, exemplified by *Milium* and *Geranium* socions; and (3) subneutrophilous synusiae, including a rather large number of sp. really dependent on a slightly acid or alkaline reaction, rather than on the nature of the soil or nitrification. However, many of these may thrive under compensating factors of good light or nutrition, on more acid media. Beech seedlings were more abundant under less acid conditions, their abundance being in direct proportion to increasing pH value. No correlation seems to exist in their case with nitrification or mull conditions. Contrary to the findings of Bornebusch, no correlation could be found between site qualities for beech and the ground flora. Modern silvicultural practice has influenced tree growth in one way and the distribution of floral types in another. The northern limit of beech is controlled by the possibility of successful reproduction. Flowering occurs every other year in response to inner periodicity, but influenced some by high maximum air temp. of the preceding June-July. The intensity of heat seems to be more important than its duration. Freezing of flowers in spring is the limiting factor to the northward spread of beech and has probably made the distribution of beech sporadic. Pollen analyses have given a good picture of its range in Boreal and Atlantic times. The limited range of beech in Western Europe does not seem to have been due to drought; in the coastal districts spring frosts were the chief cause. Sub-boreal climates were unfavorable, but changed to become very favorable about 1000 B. C. In sub-Atlantic time beech was dominant in southwestern Sweden. Man has exerted a profound influence on the distribution by cutting and burning; the latter resulted in the encroachment of *Calluna* heaths on the beech areas. This devastation reached its height toward the end of the 18th century, and was corrected by ordinances enacted after Danish examples. Present tendencies are toward a decrease in the beech area in favor of planted spruce. The Scandinavian beech forest regions are (1) the southern beech area, inclusive of Denmark (except the island of Bornholm) and the provinces of Skåne and northern Halland in Sweden, where beech is the dominant forest tree, due in part to the inability of oak seedlings to survive under beech cover; (2) the beech-spruce region, including the Norwegian beech forests, and those in south-central Sweden; and (3) the outpost beech region, consisting of scattered small stands or individual trees, possibly relics of larger stands of sub-Atlantic time.—*H. I. Baldwin.*

15354. **LITARDIÈRE, R. de, et G. MALCUIT. Contributions à l'étude phytosociologique du littoral du Boullonais: l'estuaire de la Slack.** *Arch. Bot. Bull. Mens.* 1(7): 121-137. 2 pl. 1927.—The estuary of this small stream emptying into the English Channel a short distance south of Calais is characterized by 2 littoral zones, the "slikke" between tide marks and the "schorre" submerged by spring tides only. The former has a muddy surface over sand and is covered with rather open associations of annual *Salicornia* spp., notably *S. europea* and its varieties, and of *Spartina glabra* var. *pilosa.* The "schorre" is a salt meadow dominated by an association of *Atropis maritima* together with facies of *Atriplex porticlacoides* and stands of *Festuca rubra* and *Agropyrum repens* var. *littorale.* Association tables are given for these communities and the succession is traced to the *Ammophila arenaria* association of the adjacent dunes and to an adjacent association of *Phragmites communis.* The mingling of halophytes and non-halophytes is carefully examined, the seasonal aspects are described, and the presence of *Spartina townsendi* is noted.—*G. D. Fuller.*

15356. **MATTICK, FRITZ. Das Moritzburger Teichgebiet und seine Pflanzenwelt.** *Rep. Spec. Nov. Reg. Veg. Beihefte* 56: 125-166. 7 pl. 1929.—In this region just north of Dresden, the numerous ponds may have been artificially developed, though the oldest map (1570) shows them much the same but more extensive. The forest was formerly mostly oak, but pine and fir now predominate. The plant associations are described and the more common plants listed for 35 of the larger ponds (0.3-87 ha.). Special studies on 5 sp. are presented. The land forms of *Acorus calamus* and *Iris pseudacorus* had more starch in their rhizomes than did the shallow water forms. Of *Hydrocotyle vulgaris,* the shade (f. *major* Schur.) and light (f. *microphylla* Lange) forms are described. The land form (f. *terreste* Glück) of *Nuphar luteum* produced flowers (contrary to Glück), but no stomata were found on the under side of the leaves. A land form of *Phragmites communis* is described.—*O. A. Stevens.*

15357. **MIKYŠKA, RUDOLF. Skalka v horách Štiavnických. (Studie geobotanická.)** [French résumé.] *Věstník Královské České Spolecnosti Nauk* [*Mém. Soc. Roy. Sci. Bohéme Cl. Sci.*] 1928 (paper 6): 1-23. Map. 1929.—There is an analysis of the forest types in natural beech forest and a discussion of their extension into the massive andesites of Skalka, 883m. The types which appear in the region are those characterized by (1) Fagetum nudum; (2) *Carex pilosa,* with 2 subtypes (*Luzula nemorosa* and *Dryopteris linneana*); (3) *Poa nemoralis;* (4) *Asperula odorata;* and (5) *Mercurialis perennis.* An analysis is appended of Calamagrostidetum arundinaceae, of meadow groves, of alder scrub, and of forest meadows. —*R. Mikyška.*

15358. **MORTON, FRIEDRICK. Guatemala.** *Vegetationsbilder* 22(1): 1-16. pl. 1-6. 1931.—The introduction includes data on the geographical, geological, and climatic conditions of the country, and a general description of the vegetation. The mean temp. on the lowland is 23-25° C. with extremes of 16° and 30°. Sugar cane has an altitudinal limit of 1600-1900 m. Rainfall ranges up to 350-375 cm. with Dec.-March relatively dry. The vegetation types include Mangrove coastal swamps and tropical and sub-tropical rain forests. In the rain forest, ferns play a very conspicuous rôle. The cultivated vegetation includes coffee, bananas, sugar cane, *Theobroma bicolor, Persea gratissima, Capsicum annuum,* and tobacco. Among the sp. illustrated are *Tillandsia filifolia, T. bulbosa, Aristolochia grandiflora, Acacia spadicigera, Marathrum schiedcanum, Stipa ichu, Canavalia obtusifolia, Jonvea pilosa, Cyathea schanschin, Plenrothallis longissima, Polypodium bernonllii, Scheelea preussii,* and *Ceiba pentandra.*—*G. D. Fuller.*

15359. **NAYLOR, GLADYS L. Note on the distribution of Lichina confinis and L. pygmaea in the Plymouth district.** *Jour. Marine Biol. Assoc. Unit. Kingdom* 16(3): 909-918. 1 map. 1930.—Both lichen spp. occur frequently throughout the area. *L. confinis* is the more generally distributed, being present, though sometimes scantily,

on most of the coast with the exception of Tinside. On the exposed shores outside the Sound itself it forms a zone 2-3 ft. wide, being especially common between Penlee Point and Rame Head. *L. pygmaea*, though very abundant on the open coast, is scanty or entirely absent along the sheltered parts of the Sound (Cawsand to Penlee, Cremyll to Redding Point, Jennycliff Bay, etc.). The distribution emphasizes the importance to both of the degree of exposure to wave action. The importance to *L. confinis* lies in the height to which the spray is flung up the rocks, since occasional wetting by salt water is essential to this sp. In the case of *L. pygmaea*, mechanical stimulus, aeration of water, and probably the removal of the competition factor—the larger fucoids being unable to maintain a footing on steep exposed rock surfaces—all play a part. The effect of light appears to be secondary, and is probably important in connection with the desiccation of the thallus between periods of immersion.—*Author's summary.*

15360. **NĚMEJC, F. Paleobotanický výzkum některých quarterních usazenin v širším okolí Ružomberku na Slovensku.** *Rozpravy České Akad. Věd a Umění, Tř. 2.* 39(44): 1-24. 3 maps. 9 fig. 1929(1930). Also as: **Paleobotanical researches in some Quaternary deposits in the surroundings of Ružomberok, Slovakia.** *Acad. Tchèque Sci. Bull. Internat. Rés. Trav. Prés. Cl. Sci. Math., Nat. et Méd.* 30: 216-241. 3 maps. 9 fig. 1929.—The study of plant remains in sinters left by thermal springs in Slovakia has led to the conclusion that in interglacial periods of the Pleistocene the forests were made up of birch, fir, and willows, together with some larch in some places. *Larix* has been retreating slowly since the Pleistocene, probably due to the warmer climate that favors other sp. rather than it. The Holocene travertines contain beech and spruce. Spruce had its time of greatest expansion before beech. In one peat deposit fir was found in the Holocene.—*B. McAvoy.*

15361. **NOVÁK, FRANT. A. Ekologické úvahy o hadcových rasách a hadcové vegetaci. [Critical notes on the serpentine types and the vegetation of the serpentine soils.]** *Věda Přírodní* 9: 18-21, 46-51, 81-88, 176-192, 239-242, 268-287, 310-314. 16 fig. 1928. See also *Preslia* 6: 42-71. 1928.—The author has established, by analyses of the vegetation and by chemical analysis of the serpentine soils, that there exist some serpentine types and some serpentinomorphs (plants linked with a serpentine substratum). These types and forms are determined largely by the chemical constitution of the soil, i.e., by Mg: Ca greater than 1, by absence of chlorides, a low concentration of sulphates, and a high content of Fe. The lithophytes growing upon the serpentines, because they have no contact with the serpentine soil but grow upon the exposed rock surface, are neither serpentinomorphs nor marked serpentine types (the serpentinomorphs described with the thallophytes and the bryophytes are for the most part xeromorphs). The vegetation and the flora of the serpentine substratum are determined also by historical, developmental, climatic, and atmospheric factors. A list of serpentine plants is included.—*F. A. Novák (transl. by P. D. Strausbaugh).*

15362. **RAMENSKIJ, L. G. Die Projektionsaufnahme und Beschreibung der Pflanzendecke.** [In: *Handbuch der biologischen Arbeitsmethoden.* Abt. XI. **Chemische, physikalische und physikalisch-chemische Methoden zur Untersuchung des Bodens und der Pflanze.** Teil 6. Heft. 1. Lief. 335.] 137-190. 7 fig. Urban und Schwarzenberg: Berlin, 1930.—Geobotanical investigations of vegetation in relation to habitat conditions are greatly facilitated by means of the projection method. The horizontal projection of the aerial living portions of plants, expressed in % of surface covered, gives a concept of the utilization by the group components of the lighted area and thereby characterizes their ability to compete under the conditions of their special vegetation layer. This is the only objective method which permits sufficiently accurate and speedy estimation of abundance. Thus the determination of the abundance over an area of 100 sq. m. on a meadow with 40-50 plant sp. with an accuracy of about 0.5% takes 40-50 min. The average projection abundance is determined by means of a grill and a scale. The former consists of a dark broad frame whose open area of 2×5 cm. is divided into cm. squares by means of white strings. Marks on the frame 0.2 cm. apart tend to greater accuracy. A mirror attached to this grill at an angle of 45° is intended for looking upward or for dense coarse tall stands. The scale of drawings (illustrated) consists of variously shaped leaves shown in varied abundance against a background. The observer holds the grill at a certain height, looks into it perpendicularly, and estimates the abundance in one small square by comparison with the scale. By making a number of such observations, an average figure is reached. If moss or lichens are being determined, the grill is held lower; if coarse broad-leaved plants, then the grill is held higher in order to cover relatively larger areas. For the successful application of this method it is necessary (1) to recognize the plant sp. by their vegetative characteristics, (2) to train the eye systematically for measuring the vegetation types under consideration, and (3) to use the various instruments, among which is described a fork with vertical prongs to obtain actual horizontal and vertical distances. Many practical suggestions and examples of the method for use under different conditions and for various purposes are given, with hints on the interpretation of data.—*T. M. Plitt.*

15363. **RAPAICS, RAYMUND, und LADISLAUS VAJDA. Das mittelungarische Bergland.** *Vegetationsbilder* 22(4): pl. 19-24. Gustav Fisher: Jena, 1931.—There is a brief description of this mountain region of Hungary and rather extensive lists of its plants. Among the species illustrated on the plates are *Quercus cerris, Lycnis coronaria, Waldsteinia geoides, Xeranthemum annuum, Scorzonera hispanica, Stipa stenophylla, Sternbergia colchiciflora, Draba lasiocarpa, Alyssum arduini, Allium flavum* and *Centaurea sadleriana.*—*G. D. Fuller.*

15364. **REES, KINGSLEY. Seashore plant associations at L'Ancresse Bay [Guernsey].** *Soc. Guernesiaise Rept. & Trans.* 11(1): 55-60. 1930(1931).—Species of 4 associations are listed.

15365. **REVERDATTO, V. W. Die Vegetationszonen der Abakansteppe (Süd-Sibirien).** *Bot. Jahrb.* 61(2/3/4): 242-262. 1 pl. 1927.—Raunkaier's method and that of counting shoots, determining dominance, etc., were used to determine Krylov's phytogeographic zones and to characterize associations in the region near the junction of the Akaban and Jenissei Rivers. The zones found were (1) the forested steppes with an herbaceous meadow subzone, and (2) the forestless meadow zone, which in turn is divided into (a) the 4-grass steppe (with *Stipa capillata, Koeleria gracilis, Festuca sulcata,* and *Diplachne squarrosa*) and (b) the coarse *Stipa-Artemisia* steppe (with *Stipa capillata, S. pennata, Koeleria gracilis,* and *Artemisia* spp.). Noteworthy are small areas of desert-steppes.—*E. H. Walker.*

15366. **RICKETT, H. W. Notes on the vegetation of Columbia, Missouri.** *Amer. Midland Nat.* 12(10): 411-419. 1931.—The region around Columbia includes tongues of prairie mixed with forested rough country. Certain limestone bluffs have a characteristic vegetation, especially those of the Missouri River. The valley of this stream exhibits also many stray sp. Certain rocky hills show sp. characteristic of the Ozark region. Invasion and competition in newly-deposited flats on the Missouri River are described. Attention is called to sp. not previously reported from the region, particularly in *Bromus, Panicum, Carex.* The local *Crataegus* is a mixture of as yet undetermined sp. or vars. Daniels' proposals in *Vernonia* are briefly discussed. Sp. collected by previous workers but not since encountered were mostly strays, many from the Ozark region.—*H. W. Rickett.*

15367. **RUDOLPH, KARL, FRANZ FIRBAS, und HANS SIGMOND. Das Koppenplanmoor im Riesengebirge. (Ein Beispiel für den subalpinen Moortypus in Böhmen.)** *Naturwiss. Zeitschr. Lotos* 76(4/5): 173-222. 2 pl., 5 fig. 1928.—The Koppenplan Moor is the largest and finest on the eastern plateau (1430 m.) of the Rie-

sengebirge. It is situated beyond the present limit of spruce forests (1200-1300 m.) in the zone of mountain pines. It is influenced by the subalpine climate on the crest of Riesengebirge, and is characterized by low annual temp., high moisture, heavy precipitation, long snow-covering, and short vegetative period. All moors on the crest of Riesengebirge belong to the subalpine type. The subsoil of the moor is granitic. The formation of its surface is various and changing. The plant associations are: *Cetraria-Cladonia; Pinus Pumilio-Myrtillus; Polytrichum; Sphagnum russowii;* Heath-Trichophoretum; *Trichophorum-S. compactum;* Trichophoretum rich in liverworts; *Carex limosa-Sph. lindbergii; C. limosa-Sph. dusenii;* and *Carex-Drepanocladus.* A scheme of succession is given; the first 2 associations are climax. The soil reaction is about pH 5 (31 tests). The postglacial forest periods were (as shown by pollen-analysis) the same as in all Bohemia: (1) *Pinus,* (2) *Pinus-Corylus,* (3) *Picea,* and (4) *Fagus-Abies.* The formation of peat began at the end of the *Picea*-period. During the growth of the moor, as shown by tests, the sp. and associations of plants were the same as today, but the quantitative relations were different. The transition of the moor from montane to subalpine type took place with the Subatlantic change of climate.—*Max Onno.*

15368. **SAMUELSSON, CARL. Studien über die Wirkungen des Windes in den kalten und gemässigten Erdteilen. [Effect of wind in cold and temperate regions.]** *Bull. Geol. Inst. Upsala* 20: 57-230. 60 fig. 1927.

15369. **SAVULESCU, TRAIAN. Die Vegetation von Bessarabien mit besonderer Berücksichtigung der Steppe.** *Bul. Agric.* [*Bucuresti*] 3: 55p. 1927.—Bessarabia is the meeting-ground of 3 botanical provinces: The Dazischian, limited by the eastern boundary of *Fagus silvatica,* the Sarmatian, and to the south of them the Palaeopontic Province, over the greater part of which extended the bed of the Pontic Sea at the close of the Tertiary. The plants forming the elements of these provinces are listed. The whole area exhibits strong zonation. From the Black Sea northwards the zones are: Halophyte associations, Artemisietum, Siccipratum graminosum (dry grassland), Siccipratum altiherbosum (the most extensive, enclosing areas of mixed forest and transition woods to steppe), and Altiherbipratum. For each zone the chief communities are given, with their edaphic, orographic, and geographic variants. The ruderal flora is classified as Apophytes (sp. also occurring in primitive non-ruderal communities), Ergasiophytes (escapes from cultivation) and Anthropochores (sp. introduced by the agency of man). Of the last group many are Archaeophytes (naturalized from extremely early times); others are Neophytes (recent incomers). The steppe is a subxerophyllous more or less closed formation with numerous different grass and shrub communities. Its origin and development since the Tertiary expansion of the Black Sea are discussed. With the change of climate at the end of the Tertiary and the on-coming of the ice-age all Tertiary xerotherms became extinct in the area, being driven to the Mediterranean. Forests reached their greatest southern extent, the accompanying grasses showing a like southward trend. There followed a warm dry desert-inducing climate, the forests retreated northward, leaving only relics in favorable situations, the loess soils were deposited and the steppe vegetation followed, poor in sp. and xerophytic. The further north the more closed were the associations. With the gradual change to the present continental climate, successive waves of invasion came from the Podolian Plateau and the Mediterranean, followed by the European-Eurosiberian-Eurasian elements, and finally the Asiatic elements. The prehistoric steppe was as extensive as that of to-day, and the present forests are mainly young invaders. This view is opposed to that of certain Russian authors, who consider that after the ice-age the forests preceded the steppe. An extended table gives, for each sp. of the steppe, its life-period, Raunkiaerian life-form, station, and grades of frequency and constancy in the different communities.—*H. H. Allan.*

15370. **SCHRATZ, EDUARD. Zum Vergleich der Transpiration xeromorpher und mesomorpher Pflanzen.** *Jour. Ecol.* 19 (2): 292-296. 1931.—Experiments performed in the arid region of southern Arizona led to the conclusion that the transpiration of xeromorphic plants under natural conditions is high. There is no definite correlation between the observed transpiration and the structure of the leaves. In fact, the transpiration of xeromorphic plants may exceed that of mesomorphic plants, since the former may have a greater water supply due to a deeper and more spreading root system. When the transpiration rate is obtained from weighing severed twigs, the determinations should be made within a minute of the time of cutting in order to obtain truer indications of transpiration of a plant in its natural environment. Individual differences even between plants of the same sp., changing external conditions, and unknown factors, as well as the structure, influence transpiration in the open.—*T. M. Plitt.*

15371. **[SERPUKHOVA, E. I.]** СЕРПУХОВА, Е. И. Сравнение методов геоботанического исследования. **[Comparison of geobotanical investigation methods.]** [German summary.] Труды Ленинградского Общества Естествоиспытателей, Протоколы заседаний, научные статьи и сообщения (*Trav. Soc. Natur. Leningrad, Compt. Rend. Séanc.*) 59 (1): 95-109. 3 fig. 1929.—Comparative study of Drude, Raunkiaer, and Ramenskii methods was made on 20 areas, of 1 sq. m., 50 of 0.1 sq. m., and 100 of 0.01 sq. m. Three kinds of communities were investigated: grassy fields, with predominance of *Festuca rubra* and *Potentilla tormentilla;* fields with predominance of *Crepis paludosa* and *Cirsium heterophyllum;* and conifer forest with *Oxalis acetosella.* It is believed that the Ramenskii method is best.

15372. **SHAVER, JESSE M., and MAGGIE DENISON. Plant succession along Mill Creek.** *Jour. Tennessee Acad. Sci.* 3 (4): 5-13. 1928.—Five different plant associations at various stages in the formation of bars and islands in this Tennessee creek are recognized; on the creek bank 6 are recognized. The plants of each association are listed, and the nature of the succession is discussed.

15373. **SIMPSON, G., and J. SCOTT THOMSON. On the occurrence of the silver southern-beech (Nothofagus menziesii) in the neighbourhood of Dunedin.** *Trans. & Proc. New Zealand Inst.* 59 (2): 326-342. Map, 5 pl. 1928.—Near Dunedin, 12 small forest areas of *N. menziesii* have been recorded; the situation and vegetation of these areas and the surrounding country are described in detail, and the question discussed whether *N. menziesii* is a new arrival or a survivor of a former forest. According to Cockayne, *Nothofagus* forest was originally the chief tree-community in New Zealand, but it has been gradually replaced on the more fertile ground by a subtropical forest of Malayan origin. This study supports Cockayne's theory.—*A. Rehder.*

15374. **SKOTTSBERG, CARL. The vegetation of Easter Island.** *Nat. Hist. Juan Fernandez & Easter Island. Bot.* 2 (4): 487-502. 6 pl. 1927.

15375. **SMALL, JAMES. The fenlands of Lough Neagh.** *Jour. Ecol.* 19: 383-388. 1 fig. 1931.—This lake, the largest in the British Isles, in an area with an annual rainfall of 30 in., is subject to winter flooding and is surrounded by areas of fenland quite distinct from the prevalent acid moors of Ireland. The floods are supposed to act as a buffer solution preventing the development of acidity in all sections flooded. On higher levels acid moors develop. The sp. of the aquatic, fen, and carr associations are listed, and comparisons are made with the flora of similar associations in East Anglia, England.—*G. D. Fuller.*

15376. **SMALL, JOHN KUNKEL. From Eden to Sahara, Florida's tragedy.** 123p. 22 pl. Science Press: Lancaster, Pennsylvania, 1929. Pr. $1.50.—An account is given of a botanical exploration of several thousand miles in the Florida peninsula and on the Florida reef in 1922, with especial reference to the destruction by

man of Florida's unique natural monuments—the hammocks and kitchen-middens.

15377. SMORODINZEW, I. A., et A. N. ADOVA. Effet des variations de la réaction actuelle du réservoir sur le coefficient acido-base de la tourbe. *Bull. Soc. Chim. Biol.* 13: 943-949. 1931.—In studies of the degree of alkalinity of water compatible with development of larvae of *Anopheles* conducted at Moscow, pieces of peat of 2100-3900 cc. were added to each of a series of reservoirs, each containing 32 liters of water from a *Carex* swamp (pH 7.29). Three of the reservoirs had equivalent amounts of Cl (0.003 *N*) added as NaCl, $CaCl_2$, and HCl. Varying amounts of NaOH and Na_2CO_3, carbonate alone, or $Ca(OH)_2$ were added to the others, giving an alkalinity of pH 9.66-10.91. The reaction became rapidly less alkaline, and was readjusted by further additions of alkalies at intervals of 2-3 weeks for 4 mo. The pieces of peat were then removed, dried, separated into external and internal portions, and the degree of absorption of the alkalies determined by extraction with acetic acid and sodium acetate of known pH. Fixation of small amounts of added alkalies occurs in the superficial 1-2 cm. of the peat; with larger amounts there is progressive penetration into the deeper layers of the peat. Additions of NaCl, $CaCl_2$, or HCl in quantities sufficient to make the water a 0.003 *N* solution did not appreciably affect the acid-base equilibrium of the peat.—*J. S. Caldwell.*

15378. STARK, PETER. Das Klima der Postglazialzeit, erläutert an der Waldgeschichte Oberschwabens. *Ber. Senckenbergische Naturforsch. Ges. (Natur. u. Mus.) Frankfurt a/M.* 59(2): 82-94; (3): 151-160. 9 fig. 1929.—Stark reviews the work of Bertsch (1924-9) on the pollen analysis of the bogs of upper Swabia, and compares the results with the work of Keller and himself in Baden and Switzerland. The forest succession according to Bertsch may be compared to the Blytt-Sernander periods, timed by DeGeer's chronology, as follows: the Sub-Atlantic period, moist and cool, present time to 900 B. C., is approximately equal to the *Picea* period with secondary increase of *Pinus* of Bertsch; the Sub-Boreal period, dry and warm, 900-3000 B. C., Bronze and late Neolithic ages, nearly equals the *Fagus* period; the Atlantic period, moist and warm, 3000-5500 B. C., middle and early Neolithic age, is of slightly shorter duration than the *Quercus*-mixed forest period; the Boreal period, dry and warm, 5500-6500, Campignien age, includes the somewhat briefer *Carylus* period; and the Pre-Boreal period, dry and cold, 6500 B. C. to last of ice, Paleolithic age, includes the earlier 3/4 of the *Pinus-Betula* period and all the *Dryas* period. The lack of exact correlation—also evident in Baden and Switzerland—is attributed to local variations of climate to be expected in more or less mountainous country, to different refuge areas of the several components of the flora, and to differing paths of migration into the area. The forest succession is, therefore, not so monotonous as in North Germany, but it may, with proper precautions, be used in time correlation as demonstrated by Bertsch at the Taub bog, where a prehistoric site had been considered on the basis of finds of bronze, as belonging to the Bronze age. Bertsch showed by his pollen analysis that it must be Neolithic, and further excavation demonstrated the correctness of his prediction. A similar Neolithic age is demonstrated for sites at 3 other bogs. At the prehistoric site of Wasserberg on Lake Feder, the exact correspondence of the maximum or climax of the *Fagus* forest with the Bronze age (later Sub-Boreal) is demonstrated.—*Kirk Bryan.*

15379. STARK, PETER. Über die Wandlungen des Waldbildes im Schwarzwald während der Postglazialzeit. *Naturwiss.* 17(1): 1-8; (2): 31-35. 1929.—The dominant tree in the Black Forest is now *Picea,* but this is evidently due to forest culture. Results of pollen-analysis in different moors have shown the following succession of forests: (1) *Pinus,* (2) *Corylus,* (3) *Corylus-Quercus,* (4) *Abies,* (5) *Abies-Fagus-Picea,* and (6) *Pinus.* The periods and successions in the Bodensee region of Baden are analogous with some regional differences. See also the preceding Abstract.—*Max Onno.*

15380. STERNER, RIKARD. Nagra sociologiska anteckningar rörande bohuslänsk lundvegetation. [Sociological notes on grove-vegetation in Bohuslän, Sweden.] *Acta Horti Gothoburgensis* 4: 265-283. 1929.

15381. STEYERMARK, JULIAN A. A study of plant distribution in relation to the acidity of various soils in Missouri. *Ann. Missouri Bot. Garden* 18(1): 41-55. 1931.—The quinhydrone electrode was used in a reconnaissance of the soil acidity of eastern Missouri with a list of some characteristic plants on each soil type. Ranges in pH values for given sp. compared favorably with results obtained by Wherry on the same sp. Tests were made on 24 samples of soil from 5 soil types. A number of sp. were found with a limited pH range, others showed an indifference towards soil reaction. It is concluded that (1) while some sp. may be treated under a definite soil type, others may not, since they tolerate a wide range of acidity and alkalinity; and (2) water content and chemical nature of the soil, as well as a number of other factors in certain combinations, in addition to acidity, probably have much to do with plant distribution.—*J. A. Steyermark.*

15382. THORNTHWAITE, C. WARREN. The climates of North America; according to a new classification. *Geogr. Rev.* 21: 633-655. Map. 13 fig. 1931.—Formulae are presented for obtaining a precipitation effectiveness (*P/E*) index for stations where meteorological data have been collected. This index is the sum of the precipitation-evaporation ratios for the 12 mo. of the yr. Similarly a thermal efficiency index (*T/E*) is obtained. From these indices for stations throughout the continent a climatic map is derived, which seems to correspond rather closely with the distribution of soil and vegetation.—*G. D. Fuller.*

15383. TILDEN, JOSEPHINE E. The distribution of marine algae, with special reference to the flora of the Pacific Ocean. (A preliminary paper.) *Proc. 3rd Pan-Pacific Sci. Congress, Tokyo* 1: 946-953. 1926(1928).—On the basis of variation in illumination from the earliest life period to the present time, the evolution and distribution of the different phyla of marine algae are explained. Thus the blue-green algae were developed during a period of weak illumination, the Rhodophyceae during a later period of stronger rays, the Phaeophyceae still later, and last the Chlorophyceae. Similarly the geographic distribution of the marine algae may be explained; one may expect to find more Chlorophyceae in the tropics than in regions of less illumination.—*V. O. Graham.*

15384. VANDERYST, H. Études géo-agronomiques congolaises. La région agronomique schisto-calcareuse. 4. *Bull. Agric. Congo Belge* 20(1): 72-89. 1929.—Savannahs and steppes are the dominant formations. The natural forest formation is greatly restricted and confined to the more favorable places. So called secondary forests have been established artificially by man or they have developed on agricultural lands subsequently abandoned. Various types of arboreous steppes intermediate between grassland and forest are described. Reasons are presented to explain why this region has never been largely occupied by primitive forests, and a list of the common native and cultivated plants is appended.—*P. D. Strausbaugh.*

15385. VERDOORN, INEZ C. Notes on the vegetation of the Fountains Valley, Pretoria. *So. African Jour. Sci.* 26: 190-194. 1929.—The vegetative aspects at intervals throughout the 4 seasons are described, with some reference to the ecology. Plants collected are preserved in the National Herbarium, Pretoria.—*I. C. Verdoorn.*

15386. WHITE, J. M. Re-colonisation after peat cutting. *Proc. Roy. Irish Acad.* 39(21): 453-476. 5 pl., 1 fig. 1930.—In Armagh, the nature of the re-colonising vegetation is determined by the inter-action of the following factors: depth of cutting, former vegetation, nature of the surrounding vegetation, and extent of the area cut. It is also frequently influenced by the period of time which has elapsed since cutting. When Callunetum has been cut, the re-colonising vegetation may be

Callunetum, Eriophoretum, Sphagnetum (moor formation); the various societies of the fen formation; the societies of the marsh formation; or one or other of the various aquatic associations. When the area cut has been occupied by any of the plant associations or societies enumerated above, the re-colonising vegetation may be either the same or one of the associations earlier in the sere.—*J. M. White.*

15387. WHITE, J. M. Pollen analysis of peat from Stoneyisland, Portumna, Co. Galway. *Irish Naturalists' Jour.* 3(10): 210-214. 1931.—A quantitative pollen investigation of peat from the above locality was undertaken to aid in dating a skeleton found embedded in the peat at the base of the bog. *Betula* pollen was the most abundant tree pollen in all samples except in sample 2 (27 dm. from the top of bog). It was hence concluded that the base of the Stoneyisland peat was formed during the post-ancylus period.—*J. M. White.*

15388. WILLIAMS, A. H. New Zealand plants and their difficulties. *Jour. Roy. Hort. Soc.* 55(1): 101-113. Map. 11 pl. 1930.—History reveals that no mammals were present until the advent of man during the 12th century, when the black rat and a small bat came as stowaways. The flora is dissimilar to that of any other country. Through a very long period of time the plant characters have not been affected by the introduction of fresh sp. from other regions; neither have they encountered gross destruction by man nor herbivores. They have contended with birds, insects, and the overcrowding by companion sp. The unique composition of the flora is shown by the fact that of the 1700 indigenous sp., no fewer than 75.4% are found in New Zealand alone. Of the comparatively small remainder that are not confined to New Zealand alone, 339 sp. are also found in Australia only, 82 in So. America only, and 30 in New Zealand, Australia, and So. America but nowhere else. In the distant past, eastern Australia (then separated by ocean from western Australia) was connected with New Zealand, but when eastern and western Australia were joined, New Zealand was separated from Australia. The plants that did not spread to eastern Australia till after the Eocene upheaval which united the 2 parts of that continent are therefore not in New Zealand. The So. American component is explained by a pre-Eocene connection to southern S. A. Some of the peculiarities of the N. Z. flora are: tropical appearance of the forests in a temperate region; rarity of deciduous trees; trees with long persisting juvenile forms; tangled undergrowth; prevalence of epiphytes and filmy ferns; and tree-like speedwells. The difficulties encountered by these plants are brought out by a comparison of the factors of climate, soil, and sunlight quality and quantity in New Zealand and in Great Britain.—*V. O. Graham.*

15389. WITT, KARL (mit Beiträgen von W. LAMPE und R. TÜXEN). Zur Waldgeschichte der Nacheiszeit im westlichen Harzvorland. *Beih. Jahresber. Naturhist. Ges. Hannover* 2: 98-115. 2 fig. 1930.—Two bogs were examined by pollen analyses. The one at Silberhohl in Seesen probably arose in early Atlantic time, and shows the retreat of oak, the almost complete disappearance of linden and elm, and the present dominance of pine, spruce, and oak. At Harriehausen pine has also increased greatly since the origin of the peat, and the forest increased in density. Pine and spruce have grown since early Atlantic time west of the Harz, while fir was not indigenous. No border horizons were discovered.—*H. I. Baldwin.*

15390. ZUMPFE, HANS. Vorarbeiten zu einer pflanzengeographischen Karte Oesterreichs. XIII. Obersteirische Moore. *Abhandl. Zool. Bot. Ges. Wien* 15(2): 1-100, 1 col. map, 5 pl. 1929.—This is a phytogeographical and phytosociological study of moor formations near Mariazell in Upper Styria, at 862 m. in the northern Calcareous zone of the Alps. The Dachstein dolomite occurs in strata below the Dachstein limestone of alpine Trias and is less permeable to water, favoring the formation of fens. Fens and moors can only be formed where no glacial sedimentation has interrupted the slow process of replacement of water by land ("Verlandung"). The climate must have been moist and cool during the whole post-glacial period. Today it is characterized by long and snowy winters, wet summers, and warm and sunny autumns. The principal plant associations of the fens and moors are those characterized by: 1. *Calluna vulgaris-Cladonia rangiferina;* 2. *Calluna-Carex goodenovii-Sphagnum;* 3. *Calluna-Sphagnum fuscum;* 4. *Calluna-S. magellanicum;* 5. *Vaccinium vitis idaea-S. acutifolium;* 6. *Equisetum limosum-Carex rostrata;* 7. *Carex lasiocarpa;* 8. *C. flava-Calliergon trifarium;* 9. *C. flava-Drepanocladus intermedius;* 10. *Trichophorum alpinum-Drepanocladus;* 11. *Drosera rotundifolia-Sphagnum magellanicum;* 12. *Menyanthes trifoliata-S. subbicolor;* 13. *Carex limosa-S. contortum;* 14. *Carex-S. dusenii;* 15. *Carex stellulata-S. amblyphyllum-S. magellanicum;* 16. *Eriophorum vaginatum-S. magellanicum;* 17. *Molinia coerulea-S. amblyphyllum;* 18. *Menyanthes trifoliata;* 19. *Schoenoplectus lacustris.* The subalpine conifer forests, the *Nardus* heath, and the subalpine meadow are also treated as physiognomical units. The moor formations are divided into fens, transition moors, and high moors, in order of succession. Their development began during the Bühl advance of the Glacial Period. Pollen analysis has shown the following succession of post glacial forests: 1. *Pinus;* 2. *Pinus-Picea;* 3. *Quercus;* 4. *Fagus-Abies;* and 5. *Picea.*—*M. Onno.*

ANIMAL

15391. CALDERWOOD, W. L. Salmon hatching and salmon migrations. 95p. Frontispiece, 3 pl. Edward Arnold & Co.: London; Longmans, Green & Co.: New York, 1931. Price 4s. 6d.—An interesting, non-technical but authoritative discussion of the present status of fish culture as applied to salmon. Briefly reviews the history of salmon propagation, especially in Great Britain, and critically discusses its usefulness in (1) introducing salmon into new waters and (2) building up depleted runs. The relative merits of natural and artificial propagation are discussed in the light of recent investigations in Great Britain, Canada and the United States. Some of the features of salmon migration, both in fresh water and in the sea, are reviewed with particular reference to their bearing on the problems of conservation. In general the book treats primarily of the Atlantic salmon (*Salmo salar*) but frequent reference is made to the results of studies on the species of *Oncorhynchus* which include the salmon of the Pacific Coast.—*W. H. Rich.*

15392. GAVER, F. van, et J. TIMON-DAVID. Observations sur la faune diptérologique du Haut-Queyras. Étude de biogéographie alpine. *Ann. Fac. Sci. Marseille* 4(1): 1-13. 2 fig. 1929.—The Guil Valley on the borders of Piémont and Dauphiné, shut in by mountain peaks over 3,000 m. high, is the centre of a specialised population. Diptera are distributed, according to the various types of vegetation, in 4 zones (or associations): (1) the lower zone, corresponding to the stream bank, rich in syrphids, bombyliids, and tabanids; (2) the larch zone, with asilids, rhagionids, *Haematopota,* and empids; (3) the upland prairie zone with abundant tabanids which attack cattle, also tachinids and *Cyrtopogon;* and (4) the snow zone, strewn with boulders, where various spp. of *Bombylius, Chortophila,* and *Peletiera* are found. The strictly mountain spp. (as *Cyrtopogon*), and ubiquitous spp. apparently unaffected by altitude (e.g., *Eristalis tenax*), should be distinguished.—*F. van Gaver (transl. by A. Cuthbertson).*

15393. GAUSE, G. F. The influence of ecological factors on the size of population. *Amer. Naturalist* 65 (696): 70-76. 3 fig. 1931.—The analysis of the experimental material published by Chapman and Terao shows that the connection between the quantity of food and level of saturating population in the flour beetle Tribolium and the influence of temp. on the level of saturating population of the water flea *Moina* may be

expressed in the mathematical form with the aid of the Gauss curve (generalized by Pearson). This gives us the possibility of predicting a mass appearance of injurious animals under certain ecological conditions. The same holds true concerning wild animals useful to man.—*G. F. Gause.*

DISEASES CAUSED BY FUNGI

15394. ABBOTT, E. V. La "marchitez" del algodón. [Wilting of the cotton plant.] *Vida Agric.* [*Lima*] 7 (77): 274-281. 1 col. pl., 8 fig. 1930.—Attention is called to the losses caused annually by cotton wilt in Peru, and the symptoms of the disease are briefly described. Control measures are discussed.—*E. V. Abbott.*

15395. DOWDING, E. SILVER. Wallrothiella arceuthobii, a parasite of the jack-pine mistletoe. *Canadian Jour. Res.* 5(2): 219-230. 1 map, 2 pl., 5 fig. 1931.—*Arceuthobium americanum* occurs on *Pinus murrayana* in Alberta and on *P. banksiana* in central and western Canada; *A. tsugensis* occurs on *Tsuga heterophylla* in British Columbia, and *A. pusillum* on *P. mariana* in Ontario. *A. tsugensis* and *A. mariana* are not infected with *W. arceuthobii*, but *A. americanum* is, in Alberta and Manitoba. *Arceuthobium* fruits become infected in Canada in the spring, about a week after fertilization. The fungus and the infected fruits then increase in size, and they attain their max. development by the summer of the following year. The ascospores are not violently discharged into the air. The spores ooze out into water when the perithecia are wet. The mature perithecium is made up of 2 compartments, the lower containing the asci, and the upper into which the ascospores are discharged and where they collect. Insects may disperse the ascospores. Ascospores sown in *Arceuthobium* decoction commence to germinate, but growth ceases after the germ tube has reached the length of about 1 mm. Attempts to inoculate the stigmas of healthy *Arceuthobium* with "sprout-mycelium" have so far been unsuccessful. —*Author's abstract.*

15396. MACKIE, W. W. A new disease [Rhizoctonia bataticola] of maize and beans. *Phytopath.* 21(10): 996. 1931.—Abstract.

15397. MITRA, M. A new bunt on wheat in India. *Ann. Appl. Biol.* 18(2): 178-179. 1 pl., 1 fig. 1931.—8 hybrids between Federation and Pusa 4 and 52, were found infected with *Tilletia* indica* (p. 178).

15398. MOORE, E. S. Internal boll disease of cotton in South Africa. *Union of S. Africa Dept. Agric. Sci. Bull.* 94. 11-18. 1930.—*Nematospora gossypii*, more rarely *N. coryli*, were associated with internal boll disease, which was further related to minute insect punctures. In isolation experiments *Dysdercus fasciatus* and *D. nigrofasciatus* were found capable of transmitting the *Nematospora*, which was also demonstrated in the mouth parts and digestive tracts of the stainers. *Nematospora* was also found in *Bauhinia galpini* and *Sterculia platinifolia.*

15399. MORITZ, OTTO. Zum Problem der Fusskrankheit [Ophiobolus graminis] des Weizens. *Angewandte Bot.* 13(2): 151-161. 1931.

15400. O'BRIEN, D. G., and E. G. PRENTICE. Leaf stripe or yellow leaf of oats. *Scottish Jour. Agric.* 13(3): 272-284. 1930.—Leaf stripe (*Helminthosporium avenae sativae*) is the most destructive disease of oats in Scotland and is especially severe in the southwest part where an average of 25% of the plants are affected. It causes a reduction in stand and in yield of affected plants. Affected seedlings may die before or after their appearance above ground. A long brown or yellow stripe occurs on the 1st leaf and later on others. The plant may succumb or outgrow this. A 2nd period of infection occurs at the flowering stage, when the uppermost leaves are attacked and killed and the development of the spikelets is retarded, the lower ones sometimes being blasted. Flower infection results in the development of mycelium within the surface layers of the grain, where it may be carried to succeeding crops. No immune varieties are known but the old straw-producing ones are somewhat resistant. Experiments with various chemicals in seed treatments showed that Ceresan is very effective and practical in controlling the disease. When thus treated, less seed is required and the yield increased.—*M. F. Barrus.*

15402. RAMAKRISHNAN, T. S. A leafspot disease of Andropogon sorghum caused by Cercospora Sorghi E. & E. *Mem. Dept. Agric. India* 18(9): 259-277. 4 pl. 1931.—A leafspot (*C. sorghi*) of sorghum has been prevalent in Coimbatore for at least 20 yr., and has been found in many other parts of the world. In India the disease usually makes its appearance about flowering time. Its severity is increased by a period of wet weather. The fungus causes numerous, elongated, reddish or brown spots or patches on the leaves and leaf sheaths. The fruiting bodies of the parasite appear on both sides of the leaf and may give the surface a grayish, velvety appearance. Isolations were made of the fungus, and infection experiments were tried on groundnut, maize, eggplant, tobacco, sugarcane, and sorghum. The results were negative on all the hosts but sorghum. Cultures of the pathogen were studied on various media, and data obtained regarding the influence on the fruiting and the growth of colony produced by varying the pH values, the concentration of medium, the different nutritive salts, the amounts of KNO_3, and the temp.—*C. Chupp.*

15403. RHOADS, ARTHUR S. Clitocybe mushroom root rot of citrus trees and other woody trees in Florida. *Citrus Industry* 12(9): 5-9; 38-40. 7 fig. 1931.—Mushroom root rot (*C. tabescens*) is reported attacking grapefruit, orange, and tangerine trees. Approximately all the 150 citrus trees thus far found infected have been on rough lemon root stock. The attacked trees range from scattered individuals to more or less grouped trees, and in some groves areas have been found where a considerable number of trees were attacked. Although new to science, this disease appears to be of long-standing occurrence in Florida citrus groves but has not hitherto been differentiated from foot rot, which it closely resembles. The root rot produced by *Clitocybe tabescens* resembles in many respects that caused by the well-known honey agaric or oak-root fungus (*Armillaria mellea*), especially in regard to habit of growth, the production of rhizomorphs, appearance of the mushroom-like fruiting bodies, and prevalence on land where oak trees have occurred. In the majority of cases, when the soil was removed from the root crown and adjacent roots for treatment, more or less of the lateral roots were found invaded by the root-rot fungus, or dead, and in most cases the tap root was also dead, even before the tops showed evidence of decline.—*A. S. Rhoads.*

15405. SILVEIRA GRILLO, HEITOR V. da. A ferrugem da goiabeira. [Guava rust.] *Revista Florestal* 1 (8): 5-6. 1930.—*Puccinia psidii* injures foliage and fruit of *Psidium goyava.* It can be controlled by wide spacing

in plantations and spraying with copper sulphate solutions.—*W. N. Sparhawk.*

15406. **SILVEIRA GRILLO, HEITOR V. da. Estudo sobre o Septobasidium albidum da laranjeira.** [Study of S. albidum on the orange.] *Revista Florestal* 2(1): 51-53. 3 fig. 1930.—This fungus, probably semiparasitic, attacks stems, leaves, and fruit of most *Citrus* spp. Warmth and humidity, such as are encountered in too closely spaced orchards, favor its growth. Spraying with a lime-sulphur solution is an effective control measure.—*W. N. Sparhawk.*

15407. **THOMAS, H. E.** Verticillosis [V. albo-atrum] of strawberries. *Phytopath.* 21(10): 996. 1931.—Abstract.

DISEASES CAUSED BY BACTERIA

15408. **PASSALACQUA, T. Una batteriacea parassita delle Aloë nei giardini di Palermo, Bacterium aloës.** [A bacterial parasite of aloes in the gardens of Palermo.] *Riv. Patol. Veg.* 19(5/6): 106-110. 1929.—Nearly all species of *Aloë* were affected by a spotting disease, more frequently near the tips of the leaves. The bacteria present were cultured and used in successful inoculation experiments on *Aloë plicatilis*. Infections were secured both with and without previously wounding the leaves. The bacteria are monotrichous, gram negative, aerobic, and spore forming. The name *Bact.* aloës (p. 110) is proposed.—*F. M. Blodgett.*

15409. **SMITH, CLAYTON O. Pseudomonas prunicola and Bacterium citriputeale.** *Phytopath.* 21(11): 1091. 1931.—In inoculations and cultural experiments, *P. prunicola* appeared very similar to, if not identical with, *Bact. syringae, Bact. citriputeale,* and *Bact. cerasi.*—*W. A. Whitney.*

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

15410. **STELLWAAG, F. Die Milbenkräuselkrankheit des Rebstockes in ihrer Differentialdiagnose gegenüber ähnlichen Schäden im Weinbaugebiet der Rheinpfalz.** *Anz. Schädlingskunde* 7(7): 73-77. 10 fig. 1931.—This mite disease was noted early in 1931 and differed from those previously recorded. It is caused generally by *Epitrimerus vitis*. Mites present on the undersides of leaves suck juices from the parenchyma, the cells dying around the puncture and forming a characteristic star-shaped figure. The attacks cause distorted growths, and the shoots fail to develop. The leaves remain small or distorted, the flowers develop poorly and often dry up. Adventitious broom-like growths frequently follow the attack. Tips of the shoots are most frequently attacked. In late summer mites seek winter quarters under bud scales and bark. Until last year the mite attack was confined to a few of the inner shoots because of the habits of hibernation. Since 1929, the attacks have become alarming. Affected vineyards are now much more numerous in the entire district and the attack was accompanied also by a great increase in the number of individuals. There are contributing factors such as weakening of the vine by the hard winter of 1928-29. On account of the numbers and spread, the acarinose has been more extensive on single vines. The author distinguishes between the acarinose caused by *E. vitis* and that caused by *Eriophyes vitis*. Attacks by the "Rebstickler," *Bytiscus betulae,* and non-parasitic injuries caused by frost and other weather conditions are described in detail and compared with symptoms caused by *Eriophyes vitis*. The attacks of the "Rebstickler" and *Eriophyes* are occasional or local, and winter killing has destroyed many vines in the region, but the mite leaf curl disease has reached almost catastrophal proportions.—*P. Garman.*

INFECTIOUS CHLOROSES (MOSAIC, YELLOWS, CURL, ROSETTE, ETC.)

15411. **BEALE, HELEN PURDY. Specificity of the precipitin reaction in tobacco mosaic disease.** *Contr. Boyce Thompson Inst.* 3(4): 529-540. 1931.—The viruses of ringspot- and cucumber-mosaic diseases were multiplied in Turkish tobacco, leaf extracts of the affected plants were then used as antigens in precipitin tests with antiserum for tobacco mosaic virus extract of Turkish tobacco. A slight precipitation resulted in the tubes containing undiluted antiserum and virus extract such as occurs when juice from healthy tobacco is used with undiluted antiserum. No precipitate was demonstrable that was specific for virus extracts of tobacco affected with either ringspot- or cucumber-mosaic disease. The specific antigenic substance in virus extract of tobacco-mosaic disease is foreign antigenic material, possibly virus itself, rather than altered host protein.—*H. P. Beale.*

15412. **BÖNING, KARL. Ueber eine Blattdeformationskrankheit an Rübe und Spinat.** *Zeitschr. Pflanzenkr. Pflanzenpath. u. Pflanzenschutz* 40(7): 315-323. 7 fig. 1930.—A leaf-deformation in beet and spinach, transmitted by several common aphid species, is described. It consists in a reduction of the leaf surface, abnormal thickening, and interference with function. A primary mark of infection is an upward rolling of the edges of partly grown leaves. If infection occurs when the plant is young a dwarfed growth results. If infection is later there is an excessive leaf-growth, the crown throwing out a rosette of small misshapen leaves. The disease is believed to be due to a specific virus, not identical with beet mosaic, spinach blight, curly-top, or the "bug-curl disease" of central Germany.—*K. Böning* (*transl. by F. M. Wadley*).

15413. **DUFRENOY, JEAN. Introduction à l'étude cytologique des plantes affectées par des maladies à virus.** *Ann. Epiphyties* 14(1): 163-174. 7 pl., 1 fig. 1928.—The various aspects of the plastids and mitochondria in plants affected with mosaic diseases were observed in both fresh and fixed material, and the staining reactions of the vacuoles are described. The degeneration of cell contents in mosaic-affected tissues appears analogous to that resulting from certain physico-chemical agents and also some parasitic fungi and bacteria.—*E. Carsner.*

Über chemische Veränderungen in Abutilonblättern bei infektiöser A-Chlorose.** *Arkiv Kemi, Mineralogi och Geologi* 10B(3, paper 13): 1-6. 1931.—White areas of *Abutilon striatum* leaves contained less catalase and tryptophane than green areas. In yellow areas the decrease in catalase was not proportionate to the decrease in chlorophyll. Amino N was highest in white areas but there was no marked difference in total N.—*A. E. Hitchcock.*

15415. **McKENNY HUGHES, A. W. Aphides as vectors of "breaking" in tulips.** *Ann. Appl. Biol.* 18(1): 16-29. 1 pl. 1931.—*Myzus persicae* is a vector of breaking in tulips, with *Macrosiphum gei* also a vector, but to a lesser degree. Experimental infestations of the variety Bartigon with these 2 species of aphid from the broken Sulphur tulips gave 63.03 and 41.36% breaking, respectively. Red break and white break are transmitted equally by the 2 species, but it is suggested that red break is an earlier stage in the development of the virus, and white break is the final stage. Experiments were carried out to ascertain if "parrot" is a virus similar to breaking and transmissible by the 2 aphid species, but the results were negative. There were indications that the virus can be transmitted from some varieties of tulip more readily than from others. Mass infections in the open gave a lower percentage of breaking than individual infections under glass-house conditions. No conclusive evidence was obtained to show that *Anuraphis tulipae* and *Rhopalosiphoninus tulipaella* transmit breaking.—*A. W. McKenny Hughes.*

15420. SMITH, KENNETH M. Studies on potato virus diseases. VIII. On a ringspot virus affecting solanaceous plants. *Ann. Appl. Biol.* 18(1): 1-15. 5 pl. 1931.—A ringspot virus affecting solanaceous plants is described for the first time in the British Isles. The reactions of *Solanum capsicastrum, S. tuberosum, S. laciniatum; S. nigrum, S. nodiflorum,* tomato, White Burley and Virginia tobacco, *Nicotiana glauca, Datura stramonium,* and *Capsicum* spp. are described. The close parallels in the behavior of the ringspot virus to the viruses of the potato-mosaic group are emphasized. The virus is able to exist in a variety of symptom expressions according to species of host plant and degree of virulence. Ringspot is thought to be an alternate symptom expression for a number of mosaic viruses, the development of the ringspot symptoms probably depending upon the degree of virulence of the virus, the type of host plant and the method of infection of that host plant. The phenomenon of temporary recovery of tobacco plants affected with the ringspot in its virulent form is well illustrated. Plants die down and then regrow for a period, temporarily symptomless, only to succumb once more to a severe attack. This may happen 2 or 3 times before the plant finally remains in a necrotic and moribund condition. In no case was the virus transmitted through the seed of affected plants.—*K. M. Smith.*

15421. SMITH, KENNETH M. Studies on potato virus diseases. IX. Some further experiments on the insect transmission of potato leaf roll. *Ann. Appl. Biol.* 18(2): 141-157. 1 pl., 5 fig. 1931.—Non-infective *Myzus persicae* can pick up the virus of potato leaf roll from an infected potato plant after 6 hr. feeding. The infective aphis is capable of transmitting the leaf roll virus to a healthy potato plant after 2 hr. feeding. The whole process whereby a non-infective aphis picks up the leaf roll virus and infects a healthy plant cannot be performed in 8 hr.; a minimum period of approximately 54 hr. appears to be necessary. The incubation period of the leaf roll virus in the potato plant averages 14 days. Descriptions and drawings are given of the 4 chief potato-feeding aphids occurring in England. Potato leaf roll has been transmitted by 3 species of aphids: *Myzus persicae; M. pseudosolani,* and *M. circumflexus.*—*K. M. Smith.*

15422. VALLEAU, W. D., and E. M. JOHNSON. The viruses concerned in a natural epiphytotic of streak in tomatoes. *Phytopath.* 21(11): 1087-1089. 1931.—By inoculations, the tobacco-mosaic and the masked-potato viruses are determined as responsible agents.—*W. A. Whitney.*

15423. VERPLANCKE, G. Contribution à l'étude histologique & cytologique d'une maladie de la pomme de terre, appelée en Amérique spindle tuber. *Acad. Roy. Belgique Cl. Sci. Mém. Coll. in 8°* 11(4): 1-42. 6 pl. 1930.—The nuclei in the diseased cells are sometimes lobed, frequently contain more than one nucleolus, and occupy a larger proportion of the lumen than in healthy cells. No x-bodies or striated material were found. The lenticels of diseased tubers are larger. The nonconducting cells of the diseased tuber in general show an increase in the ratio of length to width. The vascular cells show about the same length in diseased as in healthy tubers but a marked reduction in width, giving a greater ratio of length to width. The cells of the sprouts show an increased length and increased ratio of length to width. The rootlets are thinner than normal but show little change in the shape of the cells. The ratio of length to width is increased. Exceptions to these generalizations are noted. Detailed measurements of cells of various tissues are presented in extensive tables.—*K. H. Fernow.*

15424. WHITEHEAD, T. On the transmission of potato leaf-roll by aphides. *Ann. Appl. Biol.* 18(3): 299-304. 1 pl. 1931.—Evidence is submitted to show that *Myzus circumflexus* is as efficient a vector of potato leaf-roll as is *M. persicae.* The implications, both practical and academic, are discussed, particularly in view of the retardation in the development of symptoms shown by plants infested with *M. circumflexus* carrying the leaf-roll virus. *Macrosiphum gei* transmitted the disease only once and its importance as a field vector is still an open question.—*Author's summary.*

Teil* 22(3/4): 131-135. 1931.—Experiments showed that the mottling or chlorophyll accumulation frequently observed in leaves of cereals growing on slightly acid soils is not a symptom of acid injury, but is due to Mg deficiency.—*Author's summary (transl.).*

15427. KOSTOFF, DONTCHO. Tumors and other malformations on certain Nicotiana hybrids. *Zentralbl. Bakt. II. Abt.* 81(8/14): 244-260. 18 fig. 1930.—Certain species hybrids of *Nicotiana* formed tumors and other malformations on the roots, stems, branches, and leaves. No microorganisms were isolated from the tumors, and inoculations of tumor extracts failed to produce tumors on the parental plants. Tumors transplanted on the parent plants grew well but the parent plants themselves formed no tumors. Parent plants, grafted on the hybrids that formed tumors, grew without forming tumorous outgrowths. The hybrid stocks formed tumors only to the callus line. If extract of the paternal plant of the hybrids forming the tumors was mixed with extract of the maternal plant a precipitation reaction took place in vitro. Those hybrids whose parental extracts gave no precipitation in vitro did not form tumors. The suggestion is advanced that human cancer might be a result of the blood group agglutination phenomenon. From this point of view cancers are to be expected at a relatively early age in progeny where the greatest mutual agglutination reaction occurs in vitro between the parental groups, i.e., between $A \times B$ or vice versa. This hypothesis found support in 2 instances. The histological and cytological conditions found in the tumors (accumulation of starch and tannin, cytoplasmic enrichment, specific vacuolation, multinucleation, retardation of the mitotic processes, irregular cell division, polyploidy, nuclear and nucleolar hypertrophy, increases in the number of nucleoli, etc.) are considered as secondary phenomena.—*D. Kostoff.*

Sci.* 27: 253-258. 1930(1931).—During January, 1930, the temp. of the central Washington fruit districts dropped low enough to cause 3 types of winter injury to fruit plants: root killing, collar rot, and top injury. The 1st and 3rd forms are here discussed. From Jan. 6-25, the min. temp. ranged from −16 to +9° F. and the max. from 9-18° F. A survey was made of factors involved in root injury. Injury to the tops of cherry trees was studied from the standpoint of leaf area, number and size of fruit, and yields. Other fruits included in the study were peaches, apricots, apples, pears, plums, and English Walnuts.—*W. J. Bach.*

DISEASE RESISTANCE AND PARASITISM

15429. BROOKS, F. T., and G. H. BRENCHLEY. Silver-leaf disease.—VI. *Jour. Pomol. and Hort. Sci.* 9

(1) : 1-29. 2 fig. 1931.—The results of further experiments on the formation of "gum-barriers," associated with invasions by *Stereum purpureum*, and below wounds not invaded by parasitic fungi, are described, and the mechanism of gum-barrier formation is discussed. The incidence of silver-leaf disease in plum suckers, stocks, and young nursery trees is described. In numerous young "worked" trees affected by the disease, the fungus had entered through one or other of the wounds made in cutting back the stem of the stock in the process of propagation. Hot, dry summers promote recovery from the disease. The greatest danger of widespread infection in plum trees occurs after heavy cropping leading to breakage of the branches, especially when followed by a wet autumn.—*F. T. Brooks.*

Bot.* 23: 245-250. 2 fig. 1930. —Counts of the number of stalks per plant and the number of leaves per stalk of smut-infected and healthy plants of millet showed an appreciably larger mean of both stalks and leaves for the infected plants, indicating a stimulative effect of the smut mycelium on the millet plant.—*L. E. Wehmeyer.*

15431. CALDWELL, JOHN. The physiology of virus diseases in plants. II. Further studies on the movement of mosaic in the tomato plant. *Ann. Appl. Biol.* 18 (3) : 279-298. 4 pl., 1 fig. 1931.—The movement of tobacco mosaic virus in tobacco and tomato was similar to that of aucuba mosaic. The majority of the experiments were carried out with aucuba mosaic in tomato. Filtered virus juice from infected plants was readily absorbed at the cut end of a petiole and thence traveled into the xylem of the main stem. The removal of the treated petiole within 48 hr. prevented infection, but, when the petiole was left attached, the inoculated plant developed symptoms in the usual manner. In another experiment, after removal of the inoculated petiole, the leaves above were crushed. Infection resulted. In experiments in which the living tissue of an internode was killed by steam, it was found that the virus could be carried mechanically in the xylem across the dead tissue. In no case did crushing of the leaves induce symptoms on the upper part of the plant when inoculation had been made on the lower side of the "steamed" internode. The virus did not normally enter the water stream, but when it was introduced experimentally it circulated though there was no mechanism by which it could leave the vessels. The absence of the virus from the hydathode exudate was demonstrated. Apparently the virus cannot enter an unbroken cell, nor can it move through or out of dead cells. Great care must be taken to insure the absence of traces of toxic substances from inocula, otherwise infection may be prevented. The rates of movement of the virus in the tomato are practically the same upward or downward. The slightly greater rate of upward movement is attributed to greater metabolic activity in the upper portion of the plant. The movement of the virus agent along the protoplasmic strands was demonstrated by inoculating plants with infective juice after the removal of large portions of the vascular tissue. This treatment did not delay the migration of the virus up the stem. Darkness had no marked effect on the multiplication of the virus in the tissues. Prolonged periods in darkness caused permanent wilting of both healthy and diseased plants.—*J. Caldwell.*

Das Überwintern von Puccinia ribis DC. in vegetativem Stadium in den Winterknospen der Wirtspflanze. *Arkiv Bot.* [*Stockholm*] 23 A (7) : 1-7. 2 fig.; 8-18. 6 pl., 2 fig. 1931.—5. The nucleoli, previously noted in the cereal rusts as arising from the host nucleus, occur also in mallow rust. They may arise in the plasma outside the nucleus or by the partial or complete dissolution of the nucleus. The fungus nucleoli increase by fission. They are a stage in the separation into distinct entities of the fungus and host which have lived together as symbionts. 6. *P. ribis*, a *Micropuccinia*, germinates in the spring and has a specialized form which infects *Ribes rubrum* but not *R. nigrum* or *R. grossularia*. Epiphytotics arise from overwintered teliospores and from thick walled resting cells (chlamydospores). Plasma masses in the petioles of infected leaves are interpreted as mycoplasma.—*F. A. Wolf.*

15434. FAHMY, TEWFIK. Étude de la pénétration du champignon Fusarium vasinfectum (Atk.) var. aegyptiacum T. Fahmy dans les racines du cotonnier. 70p. 3 col. pl., 28 fig. Thesis, Univ. Genève. Imprimerie Jent: Genève, 1930.—The development of cotton-growing in Egypt began with the introduction of seed from the U. S. A. and India: since then several varieties have been evolved. Wilt disease appeared in 1902 when Mit Afifi was the principal variety grown. It increased in importance with the extension of Sakalleridis, a very susceptible variety. The penetration of the parasite causing sore-shin was studied in comparison with that of *F. vasinfectum*. The sore-shin parasite attacks the seedling cotton plant by invading the tissue of the hypocotyl when the temperature is suitably low, while the wilt fungus enters the root later on when the temp. is high. The wilt parasite invades first the root cap, forming a sort of ectotrophic mycorrhiza. The hyphae of the parasite are then able to penetrate the root proper, first by invading the tissue near the root cap and then progressing through the intercellular spaces and sometimes penetrating some of the cells until they reach the tracheal vessels, which they enter. Their invasion is limited to vascular tissue. The root system of young plants of susceptible varieties rots and disintegrates. On artificial media the parasite utilized nitrate more readily than ammonia; of the carbohydrates tried, glucose produced the best growth.—*T. Fahmy.*

15435. FLOR, H. H. Factors influencing the severity of the root rot troubles of sugar cane. *Louisiana Agric. Exp. Sta. Bull.* 212. 40p. 10 fig. 1930.—The root-rot complex or growth failure of sugar cane has been the most important factor in the failure of a number of varieties in Louisiana. Steam sterilization of root-rot-contaminated soil resulted in greatly increased growth. No other soil treatment appreciably benefited the cane. Certain soil animals are known to injure cane roots. A species of *Pythium* also parasitized roots of corn as well as sugar cane. Excessive soil moisture increased this injury. Tests showed that *Pythium* was more injurious to corn roots below 25° C. In culture solutions the cane *Pythium* grew over a pH range of 5.2 to 10. The *Pythium* invaded all the tissues of the young roots, producing a soft rot and subsequent collapse of the root cells. Penetration of the young roots seemed to take place through a combination of solution and pressure.—*E. C. Tims.*

15437. HARRINGTON, J. B. The effect of temperature on the expression of factors governing rust reaction in a cross between two varieties of Triticum vulgare. *Canadian Jour. Res.* 5 (2) : 200-207. 1931.—2 random populations of F_2 plants of the cross Marquillo × Marquis were tested for the reaction of their F_3 seedling progenies to form 21 of *Puccinia graminis tritici* in the greenhouse, at average daily temp. of 69.7° F. (the warm test) for one population, and 60.6° F. (the cool test) for the other. In both tests Marquis was susceptible and Marquillo was resistant. In the "warm test" 10 families of a total of 781 were resistant. In the "cool test" 5 families of a total of 301 were susceptible. In both cases the results fitted a 63 : 1 ratio excellently, indicating the operation of three main genetic factors for rust reaction. A genetic hypothesis is proposed

that explains the results on the basis of the influence of low temp. in curtailing the action of 3 susceptibility factors A, B and C carried by Marquis. The results indicate that genetic studies on characters which are easily influenced by environmental conditions should be made under controlled conditions, after ascertaining in advance the general effects of different temp., etc., upon the hybrid material to be used.—*Author's abstract.*

15438. **ISBELL, C. L. Nematode resistance studies with pole snap beans.** *Jour. Heredity* 22(6): 191-197. 5 fig. 1931.—2 selections from unnamed varieties of pole snap beans proved highly resistant, if not entirely immune, to nematode invasion under conditions in which standard varieties of pole snap beans and lima beans were heavily infested. Both were heavy yielders and one compared favorably in quality with such varieties as Kentucky Wonder and McCaslan.—*L. M. Dickerson.*

15439. **JOHNSON, THORVALDUR. Studies in cereal diseases. 6. A study of the effect of environmental factors on the variability of physiologic forms of Puccinia graminis tritici Erikss. and Henn. Pt. 1. Studies on the effects of environmental factors on the uredinial development of certain physiologic forms of Puccinia graminis tritici. Pt. 2. Studies on the effects of environmental factors on the formation and germination of teliospores of certain physiologic forms of Puccinia graminis tritici.** *Canada Dept. Agric. Bull.* 140. 76p. 9 fig. 1931.—Pt. 1. Temp. produces striking results on the reactions of some wheat varieties to certain physiologic forms of *P. graminis*. At a relatively low temp. (60° F.) and a low to moderate light intensity, these varieties are immune. At a high (75°), with the same light intensity, these varieties are completely susceptible. As the light intensity is increased, temp. and other conditions remaining constant, the host reaction is gradually shifted towards susceptibility. However, this effect is confined to the reaction of certain wheat varieties (particularly durum wheats) to certain physiologic forms. The same varieties when infected by other physiologic forms show no such response to changes in these factors. CO_2 concentrations within the range of 0.03 to 4.5% failed to stimulate rust development. There was, on the contrary, a decrease in pustule development at all concentrations above 1.5%. Pt. 2. Teliospore formation was somewhat more rapid at 70°-75° F. than at 55°-60° F. Different physiologic forms differed greatly in their rate of teliospore formation, some producing telia in a few days, others only after many weeks. The method of germinating teliospores formed in the greenhouse consists in freezing the wet teliospores for about 2 weeks in a refrigerator at −5° C.; spraying them with cold tap water for about one week, and subsequently wetting and drying the spores alternately (wet 2 days, dry 2 days), until germination commences. The spores usually began to germinate after the first or 2nd period of drying.—*T. Johnson.*

15440. **JOHNSTONE, K. H. Observations on the varietal resistance of the apple to scab (Venturia inaequalis, Aderh.) with special reference to its physiological aspects.** *Jour. Pomol. and Hort. Sci.* 9(1): 30-52; 6 pl.; (3): 195-227. 8 pl. 1931.—A study of spore germination and penetration by *Venturia inaequalis* suggests that no factors are sufficient in themselves to distinguish resistant and susceptible varieties of the apple. Certain characters—protective hairs, for example—reduce the liability of an organ to infection, and morphological characters (varying with age) in the cuticle modify the period of susceptibility of some varieties. Variation in the vitality of the parasite affects germination and infecting power. The importance of an adequate water supply is emphasized. Desiccation following wetting is injurious to the fungus, and this is correlated with reduction of germination and of infection among trees where free circulation of air obtains. Strains of the fungus exhibited differences in infective power, and some virulent and biologically specialized strains of the fungus were detected. True resistance depends on the physiological relationships of host and parasite within the leaf. Experiments on the effects of liquids expressed from leaves and fruits on spore germination reveal that, within a wide range of variation, liquids derived from resistant varieties are constantly more toxic to spores than liquids from susceptible varieties. Experiments made upon trees of the same variety undergoing different nutritional treatment show a similar relationship of toxicity with infection. Parallel inoculation experiments on trees under different nutritional conditions show that the period of incubation is longer in the variety Bramley's Seedling than in Worcester Pearmain but show no relation to the nutrition of the tree. A lower proportion of infection occurs in trees of both varieties which are deficient in N or receive rainwater only. Persistence of individual lesions is shorter in Bramley's Seedling than in Worcester Pearmain, remarkably short in trees deficient in N, and longer in trees deficient in K.—*K. H. Johnstone.*

15441. **KÖHLER, E., und J. LEMMERZAHL. Über die Prüfung von Kartoffelsorten im Gewächshaus auf ihr Verhalten gegen den Kartoffelkrebs (Synchytrium endobioticum).** *Arb. Biol. Reichsanst. Land- u. Forstwirtsch.* 18(2): 177-188. 1930.—Results from testing 100 new potato seedlings, obtained directly from the breeders thereof, are analyzed with the object of precisely determining the variable degrees of resistance or susceptibility to infection by the potato wart organism. The degrees of infection are designated as follows: (1) full infection (mature soral sporangia produced), (2) sub-infection (development of sorus abortive), (3) leaf overgrowths, (4) adventitious overgrowths. The distribution and density of infection types (1) and (2) are also taken into consideration in estimating the degree of resistance or susceptibility, and a numerical "index of infection" is then computed. The same set of seedlings was also tested by Spieckermann's method of inoculating with a compost of resting sporangia, and in the production of overgrowths the 2 methods agreed exactly. A statistical analysis of infection of 421 lines of potatoes was next made, whereby the variability of the degree of infection (index classes 0 to 4) was shown to be representable by a bimodal curve. When the lines showing subinfection were segregated, a normal frequency distribution was shown for the index classes characteristic of full infection. A difference in density of infection and type of response to infection may be shown by some potato lines when inoculated at different periods—for example, early as compared with late during winter storage, infection tending to become more severe with increasing strength of germination as the season advances. The variety Roode Star obtained from 2 sources showed practically the same index of (full) infection, is therefore not resistant. For practical purposes potato varieties having an index of infection below 0.5 may be designated as wart-resistant.—*F. Weiss.*

15442. **MACKIE, W. W., and KATHERINE ESAU. A preliminary report on resistance to curly top of sugar beets in bean hybrids and varieties.** *Phytopath.* 21(10): 997. 1931.—Abstract.

15443. **MALHOTRA, R. C. Biochemical investigation of mosaic in Solanum tuberosum.** *Jour. Biochem. Tokyo* 13: 473-487. 1931.—Analyses of aerial parts of Burbank potato plants 6 weeks old, collected 10 days after inoculation with mosaic, showed lower total fresh and dry weights, higher percentages of dry matter, N, and cellulose, with lower percentages of ether extract, starch, hemicelluloses, and non-reducing sugars, and lower total calories of heat per gm. of dry matter than did healthy plants of equal age. Reducing sugars and ash were not significantly different.—*J. S. Caldwell.*

15444. **SCHILBERSZKY, KARL. Die Gesamtbiologie des Kartoffel-Krebses.** 72p. 2 pl., 8 fig. F. P. Datterer & Cie: Freising/München, 1930. Price 4.50 M.—The author gives a comprehensive review of his discovery of potato wart in Hungary in 1896 (correspondence and specimens received in 1888-89 were indicative of its earlier presence) and of the subsequent literature which bears particularly on the morphology and taxonomic

relationships of the causal organism. This includes a critical discussion of the delineation of the Synchytriaceae, of the genera which comprise the family, and of the relationships with other forms in the order Chytridineae, especially the Olpidiaceae and the genus *Chytridium*. The life history of the potato wart fungus is reviewed in considerable detail, based on the literature and the author's own observations. He records the occasional occurrence of the soral stage with only a single sporangium, and considers that the resting sporangium is an analogous structure derived by reduction from a resting sorus. The occurrence of a mono-sporangiate sorus is considered as an atavistic reversion to the *Chytridium* type but is not indicative of a taxonomic relationship. The following points of difference between the potato wart fungus and the typical *Synchytrium* are stressed: (1) the number of sporangia in a sorus is always small (2-5), in *Synchytrium* the number is 30-40, and may reach 250; (2) the formation of zoospores (in the soral sporangia) is not accomplished by a fragmentation of the protoplasm as in *Synchytrium;* (3) the liberation of zoospores occurs through an irregular rupture of the sporangial wall, not, as in *Synchytrium*, through a pore; (4) the resting spore has a 3-layered membrane of which the outer is derived from the host cell—there is no certain analogue in *Synchytrium;* (5) the zoospores are of 2 sizes, those of the soral sporangia being smaller; the zoospores are facultative gametes and may copulate to produce a zygote which develops into a resting spore—in *Synchytrium* copulation of zoospores is not known; (6) the wart fungus is not limited to an epidermal position in the host, but is found deep in the tissues, being carried there by host cell divisions under the stimulus of the resting spore; this gives rise to a massive hyperplastic tissue which may contain vascular elements—there is nothing analogous in *Synchytrium;* (7) all the *Synchytrium* spp. which inhabit terrestrial plants infect only aerial organs —the wart fungus only exceptionally does so, and is well adapted to an existence in the soil. On these premises the genus *Chrysophlyctis* is maintained, and a new diagnosis is presented, the wart fungus retaining the name *C. endobiotica*. *Chrysophlyctis* is assigned to a subdivision of the *Synchytriaceae* along with *Eusynchytrium*, characterized by the development of a sorus of zoosporangia, and the possession of a resting sporangium (which may also produce a sorus) in addition to the summer sporangium stage.—Particulars of geographic distribution, host range, the relative susceptibility of potato varieties, and control by resistant varieties, extermination and exclusion are included.—*F. Weiss.*

15445. SIDERIS, C. P. Pathological and histological studies on pythiaceous root rots of various agricultural plants. *Phytopath. Zeitschr.* 3(2): 137-161. 1931.—The pathogenicity of various spp. of *Nematosporangium, Pythium, Pseudopythium,* and *Phytophthora* was studied on a great variety of plants (*Saccharum officinarum* vars. Lahaina and H-109, *Zea mays, Musa sapientum, Ipomoea batatas, Pennisetum barbinodum, Cajanus indicus* var. New Era, *Vicia faba, Canavalia ensiformis, Vigna sinensis, Phaseolus aureus, Triticum vulgare, Allium cepa, Solanum tuberosum* and *Helianthus annuus*) and found to vary in aggressiveness in respect to the different parasites, and in susceptibility in respect to the different hosts. The different *Nematosporangium* spp. are, as a group, more pathogenic on the roots of monocotyledons than on dicotyledons; the reverse obtains with *Pythium* spp. The *Phytophthora* spp. and *Pseudopythium phytophthoron* are highly pathogenic to roots of onion, which are almost immune to the *Nematosporangium* and *Pythium*. The theory of "chemical stimuli" for the initial development of parasitism rather than that of "mechanical pressure" is favored. *Triticum vulgare* was highly susceptible to all *Nematosporangium* spp., for which reason it is recommended as a relatively reliable test plant.—*C. P. Sideris.*

15446. SIDERIS, C. P., and G. E. PAXTON. Pathological, histological and symptomatological studies on pineapple root rots. *Amer. Jour. Bot.* 18(6): 465-498. 25 fig. 1931.—The susceptibility of pineapple roots to species of *Nematosporangium, Pythium, Pseudopythium,* and *Phytophthora* varied between the different genera and also between the different species of the same genus. 9 species of *Nematosporangium*, 11 of *Pythium*, 1 of *Pseudopythium*, and 2 of *Phytophthora* were pathogenic, some highly aggressive and others very weak parasites. Of the species of *Nematosporangium* studied, *N. rhizophthoron* and *N. polyandron* are responsible for the greater portion of root rot attributable to this genus. Species of *Pythium* are less pathogenic to pineapple than those of *Nematosporangium* but are responsible for some of the root rot noted. The most active species are *P. splendens, P. diameson* and to a small extent *P. artotrogus* and *P. irregularae*. The amount of root rot caused by *Pseudopythium phytophthoron* and 2 species of *Phytophthora* is small and mostly restricted to winter months. Approximate, and in certain cases accurate, identification of various pythiaceous organisms in the tissues of the roots is possible on the basis of the morphology of the reproductive organs. Root rot of this type is probably one of the important factors in pineapple "wilt." Various *Fusarium* spp. have also been assigned an etiological rôle in this disease. A species closely related to *F. affine* was able to establish itself on devitalized or dead small laterals, kill the healthy tissues by means of toxic metabolic by-products, and then make its inward advance. Injured roots may recover if the injury is light or die if it is severe. Drought conditions responsible for the death or devitalization of laterals favor infection by this organism. The damage caused by this organism under field conditions is probably of minor importance. A *Verticillium*, closely related to *V. buxi* and *V. heterocladum*, isolated from diseased pineapple roots, caused injury or death on inoculation into roots. Economic losses from this organism are low. The rate at which root rot is caused by the different organisms seems to correspond with the quantities of pectolytic enzymes which they are capable of producing.—*C. P. Sideris.*

15447. TOGASHI, KOGO. Studies on the pathology of peach canker. *Bull. Imp. Coll. Agric. and Forest. Morioka* 16. 178p. 2 pl., 34 fig. 1931.—The peach form of *Leucostoma persoonii* also infects plum, apricot, cherry and nectarine trees; the peach form of *Valsa japonica* also infects cherry, mume, apricot, and nectar trees. The mycelia generally do not penetrate to the xylem, probably due to excessive gum deposition in affected tissues. Development of wound periderm and callus tissue is notably less at the upper and lower edges than along the sides of the stem lesions. From such unprotected zones the hibernated mycelium initiates growth and forms a new canker around the old one. The pH of expressed bark juice of healthy peach twigs is about 5. Medullary rays of phloem and cambium just beneath show the highest pH of bark tissues; phloem and cambium, the lowest; pH of cell contents in the inner cortex is 4.4-5.8. The pH of affected tissues is generally somewhat higher. Gum pockets are formed in embryonic woody tissues immediately after infection, and the amount of exuding gum indicates the relative virulence of the invader. In sections of diseased twigs, discolored areas showing gummification are observed to occupy large areas without external signs. Hemicellulose, cellulose, dextrin, pectin, and starch were found suitable nutrients for culturing the fungi; sucrose, maltose, and amygdalin were in general unsuitable. Both fungi secrete diastase, invertase, maltase, emulsin, hemicellulase, pectinase, and cellulase, the last 3 being most active. The cellulase seemed unable to decompose filter paper and absorbent cotton celluloses. In general, the enzymes of *L. persoonii* were the more active, and tended to act more pronouncedly at higher temp. As a whole, pH 3-7 is the most favorable range for the enzyme activities of these 2 fungi. Relations of the fungi to pH in culture correspond with their reactions to pH in the peach branch. During active leafy stages of peach trees, the temp. of the branches

almost parallels that of the air; during the dormant stage, it is often much higher than the air temp. *L. persoonii* is more thermophilic than *V. japonica*, suitable temp. being 5° or more higher. *L. persoonii* is widely distributed in Japan, *V. japonica* is limited to the northern part of Honshu and Hokkaido. Affected tissues begin to enlarge in early spring; this is especially conspicuous on the south sides of branches. Considering the difference in temp. fluctuations between north- and south-side branches, it is probable that tissues on the south side are more tender. This seems to be an indirect cause of the sun-scald frequently seen on south-side branches. Considering the chemical constituents of peach tissues in which gumming occurs plus the characteristics of the enzymes secreted by these fungi, it is inferred that the gumming process is accelerated by the fungous enzymes. Gum formation is considered as a protective reaction of the tree against external injurious influences. The advance of the healing process against these parasites seems to depend on the growth condition of the host at the time, and on its stage of growth when infection was initiated; promotion of healing coincides well with the growth activity of the tree. In the Morioka region, the period for precautionary measures against infection seems to be from mid-August through the first third of November.

15448. WELLENSIEK, S. J. De vatbaarheid voor slijmziekte van 32 geïmporteerde aardappelrassen. (The bacterial wilt-disease susceptibility of 32 imported potato-varieties.) [With English summary.] *Korte Mededeel. Inst. Plantenziekten [Buitenzorg]* 16. 5p. 4 pl. 1931. —Susceptibility of 32 varieties to *Bacterium solanacearum* was investigated by both artificial and natural infection; the latter method gave satisfactory results. All were susceptible, but the Botergele and Dauer Rogas varieties contracted the disease at a later stage of development.

DISEASE CONTROL (SEED TREATMENT, SOIL DISINFECTION, FUNGICIDES, AND SPRAYING)

15449. BOYD, O. C. Apple scab and some new slants on its control. *Massachusetts Fruit Growers' Assoc., Inc.* 37: 58-63. 1931.—A summary of the apple disease situation in Massachusetts during 1930 indicates generally light losses from all diseases. Scab, nevertheless, caused marked losses in many commercial orchards, and extensive surveys indicated that such losses were due to failure to control the disease the preceding year, improper timing of sprays during the critical period for primary infection, difficulty in spraying closely spaced trees and inadequate pruning and thinning. Flotation sulphur compared favorably with liquid lime-sulphur in the control of scab when used in post-blossom application in a commercial orchard test, while sulphur dry lime-sulphur dust (85-15) gave less control.—*O. C. Boyd.*

15450. MARSH, R. W. Apple scab control in the Bristol Province: field trials, 1930. *Jour. Pomol. and Hort. Sci.* 9(1): 53-72. 1 fig. 1931.—Spray applications which terminated at or before the petal fall stage gave excellent control at Long Ashton from 1926 to 1929. Similar trials in commercial plantations at Bridgewater, Yeovil, Hereford, and Malvern were conducted during 1930. At the first 3 centers, scab had ruined the 1929 crop and pustules were abundantly present on twigs the following spring. At Bridgewater and Yeovil, lime-sulphur 1-30 or 1-40 was used for the first 2 applications and a weaker concentration for the third while, at Hereford and Malvern, bordeaux 4-10-50 was used for the pre-blossom applications and for the post-blossom at the latter center. Weather during the season was very favorable for scab development. Vaselined slides suspended in trees during April and May, and before scab appeared on new growth, captured conidia but no ascospores. At Hereford the concentration after 14 days was 132 conidia per sq. inch, being well-marked before pink stage, but was less in other orchards. The winter of 1929-1930 favored complete destruction of fallen leaves. On control trees, scab was first observed on May 22 and was well advanced by July 7. Excellent control (86 to 98% clean fruit) was obtained on the susceptible variety, Worcester, when sprays were applied at green flower, pink, and petal-fall stages, but was not so good when the first application was made earlier than indicated. Some slight russeting occurred on bordeaux-sprayed fruit.—*M. F. Barrus.*

15451. MASSEY, L. M., and BRUCE PARSONS. Rose-disease investigations. Second progress report. *Amer. Rose Ann.* 1931: 65-80. 1 fig. 1931.—In field experiments during 1929 and 1930, sulphur dusts were more effective than 20-80 copper-lime dust, 4-4-50 bordeaux, 1-50 liquid lime-sulphur, and a proprietary ammoniacal copper carbonate solution (Fungtrogen) in the control of blackspot (*Diplocarpon rosae*). In 1930 Ferrox flotation sulphur spray and Sulfocide also proved inferior to the sulphur dusts. Green sulphur dust with (Pomogreen) and without (Green Kolodust) lead arsenate was practically as effective as the undyed material and caused less discoloration. 20 before-rain applications were made in 1929 and 17 in 1930, while 18 and 12, respectively, applications of sulphur dust, copper-lime dust and bordeaux were made in after-rain treatments. The latter were less effective. Records for brown canker (*Diaporthe umbrina*) offer some encouragement for control through the use of sulphur fungicides with treatments starting in the seed-bed in the nursery.—*L. M. Massey.*

15452. MONTEITH, JOHN Jr. Some effects of lime and fertilizers on turf diseases. *Bull. U. S. Golf Assoc. Green Section* 9(5): 82-99. 11 fig. 1929.—Lime largely prevents, and to some extent cures, the development of brown-patch, which occurs on golf greens excessively fertilized with ammonium sulphate. Lime also lessens scald. Applications of mercuric chloride and calomel also reduce brown-patch, and the residues are not as harmful as those of copper fungicides. Ammonium sulphate is beneficial because of readily available N, but when used in excess the resulting acidity is harmful, especially in summer.—*H. H. Clum.*

15453. MOORE, M. H. The incidence and control of apple scab and apple mildew at East Malling. *Jour. Pomol. and Hort. Sci.* 8(3): 229-247. 4 pl.; (4): 283-304. 4 pl. 1930.—I. Apple Scab.—Bordeaux mixture 8-8-100 pre-blossom and 8-25-100 after blossom, or lime-sulphur sp. gr. 1.01 before blossom, sp. gr. 1.003 after blossom, applied in 1, 2, and 3 applications, gave comparably good scab control on Cox Orange Pippin but bordeaux caused severe russetting. Colloidal sulphur or lime-sulphur sp. gr. 1.003 gave poor results. Sulphur dusts gave poorer results than lime-sulphur spray. Spray results were based on shoot, leaf, and fruit infections. Cox Orange Pippin grafted on East Malling rootstocks XIII and XV had greatest resistance to scab and rootstocks I and IV had greatest susceptibility. Trees which had received a balanced manurial treatment for 10 yr. had ½ to ⅔ less scab than trees on similar rootstocks receiving no manure. II. Apple Mildew.—Observations on control of mildew were based on spraying experiments described in the preceding section. Lime-sulphur gave better control than bordeaux. Soda-soap solution 20-10-100 gave best control on Belle de Boskoop compared with sulphur fungicides. Rootstock I induced susceptibility to both mildew and scab, while rootstocks XV and III induced resistance to both in Cox Orange Pippin. Rootstock III, unworked, was susceptible to both diseases. Manurial treatments had little or no effect on mildew infection. III. Spray Injury.—Bordeaux caused leaf scorch, fruit russetting, and partial loss of crop on Cox Orange Pippin and reduced blossom trusses for succeeding year. Lime-sulphur and colloidal sulphur (0.4%) caused no injury to Cox Orange. Sulphur sprays caused severe leaf drop and reduction of crop on Stirling Castle. Rootstock may influence leaf scorch on lime-sulphur-sprayed Cox Orange.—*J. F. Hockey.*

15455. VOGLINO, PIETRO. Il controllo fitopatologico

sulla esportazione delle castagne dal Piemonte verso gli Stati Uniti d'America nella campagna 1930. [Phytopathological control of the exportation of chestnuts from Piedmont to U. S. A.] *Nuovi Ann. Agric.* 11(1): 29-44. 1931.

15456. **WILCOXON, FRANK, and S. E. A. McCALLAN.** The fungicidal action of sulphur. III. Physical factors affecting the efficiency of dusts. *Contr. Boyce Thompson Inst.* 3(4): 509-528. 6 fig. 1931.—Commercial sulphur fungicides differ significantly in toxicity to conidia of *Sclerotinia americana* when compared on an equal weight basis in laboratory tests. This difference cannot be ascribed to differences in rate of formation of H_2S, sulphur content, or acidity of the water extracts. Sulphur fungicides may be classified as "straight" or "modified" dusts and suspension or colloid sprays. Before an artificial rain test, the modified appear more toxic than the straight dusts, but after the rain test there is no difference between the groups, though there is between individual dusts. The colloidal sulphurs are the most toxic. The order of toxicity of straight dusts is unaffected by the rain test and the toxicity increases with decrease in particle size. A convenient method is described for the determination of mean particle size, which involves counting the number of particles furnished by a known weight of dust on a known area. Straight sulphur dusts of differing mean particle diam. compared on an equal weight basis show significant differences in toxicity, but on a basis of equal numbers of particles per unit area there is no difference. The finest dust is most adherent, following the rain test, both to glass and leaves. The percentage adherence decreases with smoothness of surface and quantity of dust applied. A measure of dusting quality was found in the "angle of slope" (the angle between the side and base of a cone of dust carefully built up to maximum height). The most important single factor determining the toxicity of sulphur dusts is the number of particles in a unit weight of material, the finest dust furnishing the greatest number.—*S. E. A. McCallan.*

15457. **WIŚNIEWSKI, P. Wpływ kwasu octowego na zwalczanie głowni prosa (Ustilago panici miliacei) i na kiełkowanie ziarn prosa. [Influence of acetic acid on control of millet smut (U. panici miliacei) and on the germination of millet grains.]** [With German summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest. Ann.)* 22: 363-378. 1929.—Use of 1% acetic acid for 15 min. diminished the number of infected panicles, although these results were in general poorer than with formalin. Longer exposure and more concentrated solutions (3-4% for 1 hr.) were not inferior to formalin treatments (0.5% for 5 min.). Treatments with acetic acid (3-4% for 15 min.-1 hr.) without milk of lime injured the seed more than formalin, but 1-2% acetic acid without milk of lime gave no worse results than formalin. Using 6% milk of lime with 1-4% acetic acid for 15 min.-1 hr. gave better results than formalin.—*Author's summary (transl.).*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

15458. **ABBOTT, E. V. Further notes on plant diseases in Peru.** *Phytopath.* 21(11): 1061-1071. 1931.—An annotated list of 53 diseases of economic plants not hitherto reported from Peru, together with a discussion of the most important of those already known. Sugar cane mosaic was found generally in the plantations of the Carabayllo Valley, but was not observed in other districts. Cotton wilt (*Fusarium*) is causing the abandonment of cotton culture in some sections. In field tests the Peruvian variety, Tanguis proved more resistant than several N. American varieties. Stem rust (*Puccinia graminis*) infection of wheat in the highlands decreased gradually with elevation. Germination and infection experiments indicate that the urediniospores do not survive from one crop to the next on the coast, supporting the theory that rust epidemics on the coast are initiated by wind-blown spores from the sierra. Stripe rust (*P. glumarum*) of wheat sometimes causes injury at high elevations where stem rust and leaf rust (*P. triticina*) are absent. Potato late blight (*Phytophthora infestans*) has not been found in the regions where the potato is native, indicating that it is not indigenous to S. America. Potato powdery scab (*Spongospora subterranea*) occurs throughout the Andes where the potato is native and was found once on wild potatoes, indicating its indigenous character. Wart (*Synchytrium endobioticum*) was observed in only one potato district. *Aecidium cantensis* and *Puccinia pittieriana* are reported from Canta (altitude, 8000-9000 ft.) and Tarma, resp. Diseases of fruits not previously reported include Diplodia rot (*D. natalensis*) of oranges, blue mold (*Penicillium italicum*) of citrus fruits, peach leaf curl (*Exoascus deformans*), peach mildew (*Oidium leucoconium*), and a papaya wilt (*Fusarium* sp.). Mosaics are serious on tomatoes and peppers. Miscellaneous fungi identified include *Cercospora apii* (on celery), *C. citrullina* (on watermelon), *C. zebrina* (on alfalfa), *Corticium vagum* (on 8 crops), and *Oidium* sp. (powdery mildew, on 22 plants).—*W. A. Whitney.*

15459. **CHEAL, W. F. Experiments on potato sickness.** *Ann. Appl. Biol.* 18(3): 401-403. 1 pl. 1931.—Following results already published of the effect of inoculations on potato plants with *Heterodera schachtii* and *Corticium solani* in 1928 and 1929, further pot experiments were carried out in 1930 with an additional organism, *Colletotrichum atramentarium.* The results showed a definite effect, the 1st yr. of inoculation, in those pots where *H. schachtii* was present. There was not enough evidence to support the view that the absence of *C. atramentarium* in the 1928 inoculations accounted for the slight symptoms of potato sickness produced that year compared with results obtained in 1929.—*Author's summary.*

15460. **DUFRÉNOY, J., et F. LABROUSSE. Influence du pH du milieu de culture sur la pénétration du rouge neutre dans les cellules du tabac.** *Ann. Épiphyties* 16 (2): 95-102. 5 fig. 1930.—Tobacco seed was germinated under sterile conditions on nutrient agar buffered to pH 4.4-7.5 and containing different concentrations of neutral red. Germination occurred on agar containing 20 gm. neutral red per liter but growth was soon inhibited through the death of meristematic cells in the root tips when the concentration was higher than .05 gm. Lower concentrations did not inhibit growth. Robbins' effect was noted when the seedlings did not absorb neutral red in a medium more acid than pH 5 (i.e., on the acid side of the iso-electric point) whereas seedlings grown on media of pH 5.5-7.5 absorbed neutral red in the vacuolar sap of the meristematic cells. Vacuoles so stained showed the same pattern as observed in stained sections of living tissues.—*J. Dufrénoy.*

15461. **DURRELL, L. W. The pathology of maize.** *Bull. Torrey Bot. Club* 57(4): 233-237. 1930.—A brief history showing the trend of investigational work on the various diseases [smut (*Ustilago zeae*), ear rot *Diplodia zeae*), brown spot (*Physoderma zeae*), the root and stalk diseases (*Basisporium gallarum* and *Gibberella saubinetti*), black bundle (*Cephalosporium acremonium*), et al.].—*H. H. Haymaker.*

15462. **GARD, M. Sur les causes de l'infécondité des noyers et de la vigne en 1926.** *Ann. Épiphyties* 14(2): 132-162. 8 fig. 1928.—The 2nd half of April, most of May, and June 5-20 were characterized by low temp., local freezes, or prolonged rains, conditions particularly inimical to the growth, development and functioning of the fruiting organs. Parasites, chiefly *Marssonia juglandis* and *Microstroma juglandis,* were favored by the prevailing weather conditions, the former practically defoliating the susceptible varieties. The different species of *Juglans* listed in order of their susceptibility to *Marssonia* are: *J. hindsii, J. californica, J. regia, J. cinerea, J. nigra.* The Japanese and Asiatic walnuts are nearly immune, and species of *Carya* and *Pterocarya* show practically absolute resistance. Weather conditions were also responsible for the unproductiveness of the grape vine.

Contributing causes were the damage done by *Eudemis*, the summer drouth, and the early fall freezes of 1925 which injured the immature canes and weakened the buds.—*A. G. Plakidas.*

15463. **HAARRING, FRITZ. Beizmittelprüfung an Haferflugbrand im Laboratorium mit der "Leipziger Methode."** *Pflanzenbau, Pflanzenschutz u. Pflanzenzucht* 7(3): 89-92. 2 fig. 1930.—Microscopic examination confirmed the value of the Leipzig method, but that employed by Reed was not successful because the mycelium is not present in its natural state and because of the absence of the glumes.—*G. R. Gage (from abstract by F. Haarring).*

15464. **HOLLRUNG, M. Forschungs- und Lehrtätigkeit auf dem Gebiete der Pflanzenpathologie in Deutschland.** *Proc. Internat. Congr. Plant Sci., Ithaca, N. Y., 1926* 2: 1216-1223. 1929.—The author gives a review of the development of the science of plant pathology in Germany from Plenck through De Bary to the establishment of the Biologisches Reichsanstalt für Land- und Forstwirtschaft, the organization of research and field stations in Germany, a review of current work in Germany, and of the types of instruction in plant pathology. —*L. E. Wehmeyer.*

15465. **JANKOWSKA, KRYSTYNA. O nowych dla Polski chorobach roślin uprawnych. [Some new diseases of cultivated plants in Poland.]** [With English summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest. Ann.)* 21(1): 153-162. 1929.—The following diseases of cultivated plants, new to Poland, are described and discussed: *Urocystis cepulae* on onion, *Peronospora* **ducometi** Siemaszko et Jankowska (p. 157) on buckwheat, and bacteriosis ("wild fire") of tobacco.—*Author's summary.*

15466. **KROHN, HEINZ. Wertbestimmungen des Kartoffelpflanzgutes durch neue Keimprüfungsmethoden und analytische Untersuchungen.** *Bot. Arch.* 25: 413-447. 13 fig. 1929.—Pieces weighing about 5 gm. cut from the bud end of each tuber, were used in sprouting tests to compare diseased and healthy samples of the same varieties. Tubers infected with leaf-roll, mosaic, or *Phytophthora infestans* sprouted earlier and had longer sprouts than healthy tubers of the same variety. It was impossible to identify specific diseases by the character of sprouts. Determinations of dry matter, soluble N, and protein N failed to give data that might be useful in diagnosing the value of potatoes for seed purposes. The author concludes that this method of testing is a practical way to determine the value of potatoes for seed prior to field planting.—*J. Bushnell.*

15467. **LeCLERG, E. L. Distribution of certain fungi in Colorado soils.** *Phytopath.* 21(11): 1073-1081. 1931.—A study was made of the fungous flora of 13 soils of different physical conditions supporting different crops. 31 species of fungi (in the genera *Absidia, Acrothecium, Alternaria, Aspergillus, Cunninghamella, Fusarium, Gliobotrys, Hormodendrum, Mucor, Penicillium, Phoma, Rhizopus, Serpedonium,* and *Trichoderma*) were isolated. Alkali salts tend to reduce fungous flora, although *Fusarium* spp. were abundant. Fungi were more abundant in planted than in non-planted soils, such as wind-blown soils. The number of fungi was greatest in soils producing red clover. The only forms that occurred under all soil conditions were *Fusarium* spp. These fungi were more abundant in soils that had produced wilt-sick crops of potatoes than in soils that had produced a crop of only a few affected plants. Likewise, they were very abundant in soils that had produced a crop of gladioli badly affected with Fusarium root rot. Species of *Aspergillus* and *Penicillium* outnumbered any other fungi isolated. The number of fungi decreased with depth into the soil, *Fusarium* being the only fungus present at all depths down to 6 ft.—*Author's summary.*

15468. **MARSHALL, RUSH P. A rubber dressing for tree wounds.** *Phytopath.* 21(11): 1089-1091. 1931.—Rubber latex, containing vulcanized rubber suspended in a colloidal stage, is painted on the wound surface. Combining all the advantages of many dual dressings, as well as being usable at 19°F., it is a material of wide application.—*W. A. Whitney.*

15469. **MELCHERS, LEO EDW. A check list of plant diseases and fungi occurring in Egypt.** *Trans. Kansas Acad. Sci.* 34: 41-106. 1931.—This list of the fungi and plant diseases, based on collections and records from 1820-1930, represents the most complete record for northern Africa. An organism-host and a host-organism arrangement is followed, together with dates of collections and the names of the collectors. The plant diseases include those of a bacterial, fungous, virus, and nonparasitic nature. From a survey of the crops grown in Egypt and the oases of the Libyan Desert, many diseases heretofore unreported in northern Africa are listed.—*L. E. Melchers.*

15470. **MORSTATT, H. Pflanzenpathologie als Wissenschaft und Unterrichtsgegenstand.** *Proc. Internat. Congr. Plant Sci., Ithaca, N. Y., 1926* 2: 1194-1203. 1929. —The author issues a plea for a more basic and comprehensive conception of phytopathology, with especial reference to instruction in this field.—*L. E. Wehmeyer.*

15471. **STANER, P. Les maladies du caféier dans l'Ituri et le Kivu. Rapport phytopathologique.** *Bull. Agric. Congo Belge* 20(1): 129-140. 1929.—The insect and fungous pests encountered during a tour of the coffee-growing districts of Belgian Congo are reported, with recommended measures for their control. The insects encountered include aphids and coccids (*Aphis coffeae, Dactylopius* sp., and *Lecanium* spp.); *Cemiostoma coffeela,* a leaf miner which does considerable damage in some localities; 3 species of borers causing slight damage; gray worm, a leaf-eating insect important in young plantations; nematodes; and *Stephanoderes,* a serious insect pest not yet found in the principal coffee districts. The fungous parasites include *Thyridaria tarda (Diplodia theobromae); Fomes lignosus,* causing isolated cases of root rot; *Cercospora coffeicola; Colletotrichum coffeanum; Phyllosticta coffeicola;* and *Hemileia vastatrix.* The last named fungus causes serious damage in plantations at altitudes of less than 1000 m., comparatively little at elevations of about 1500-1600 m., and is not found above 2000 m. Substitution of the more resistant *C. robusta* for *C. arabica* in plantations with elevation of less than 1000 m. is recommended. Considerable discussion is given a physiological disorder known as "die back," which follows a weakened condition of the trees brought about by overproduction, defoliation by rust, unfavorable soil, or poor cultural methods.—*B. B. Higgins.*

15472. **STANER, P. Quelques maladies de l'Hévéa.** *Bull. Agric. Congo Belge* 21(3): 649-658. 10 fig. 1930. —The root diseases caused by *Fomes lignosus* (=*F. semitostus*=*Rigidoporus microporus*); *F. lamaoensis* (=*Hymenochaete noxia*); *F. pseudoferreus* (=*Poria hypolaritia*) are described and control measures detailed. *Ustulina zonata* is a wound parasite. A physiologic disease caused by excessive soil moisture is reported. A case of polyphagy of *Fomes lignosus,* living as saprophyte on roots of *Ficus* sp. and as a parasite on roots of *Hevea, Leucaena,* and cacao tree is described. Both cacao and *Hevea* being susceptible to the same root disease, the culture of the former tree as shade plant for the latter is not recommended. A new disease of *Hevea* caused by *Corticium* sp. is described. The bark (60 cm. from ground level) is killed to the cambium and is covered by gray-perlaceous, white-bordered, zonate plates of the fungus. The roots are healthy. Scraping and application of tar are prescribed. An analytical key for the determination of root diseases (including that caused by *Sphaerostilbe repens*) is given.—*R. Ciferri.*

15473. **TILEMANS, EM. Comment lutter contre les maladies de l'Hévéa.** *Bull. Agric. Congo Belge* 21(4): 1196-1202. 1930.—Wet rot (*Fomes pseudoferreus*) and the similar diseases caused by *F. lignosus, F. lamaoensis,* and *Xylaria thwaitesii* are controlled by isolation of infected trees and liming. Soil sterilization of seedling-nurseries is useful. Dry rot of trunk and branches

(*Ustulina zonata*, a wound parasite) is controlled by scraping and an application of tar. Mouldy rot (*Sphaeronema fimbriatum*) is spread by tapping knives and is epidemic only during wet, warm seasons. Canker (*Phytophthora faberi*) is a serious disease. Disinfection of tapping surfaces by Uspulun (0.1%) is prescribed. Seedlings affected by *Pestalozzia palmarum* are to be burned and the soil disinfected by applying 5% Uspulun at the rate of 5 liters per sq. m. The following fungi causing leaf diseases are briefly discussed: *Helminthosporium heveae*, *Phyllosticta heveae*, *Phytophthora* sp., *Colletotrichum heveae*, *Cercospora cearea* (sic), *Glomerella cingulata*, and *"Chaetopelopsis tennuissina." Oidium* is controlled spraying with sulphur and copper sulphate mixtures. The Brazilian leaf disease caused by *Dothidella ulei* is cited, as well as the Alga, *Cephaleuros virescens*. Insect pests are not important. Paranitrophenol ("Mouldex") is used for the prevention of moulds on raw rubber. An alteration of raw rubber caused by bacteria or yeasts is little known.—*R. Ciferri.*

GENERAL

15474. JAMES, W. O. An introduction to plant physiology. viii + 259p. 1 pl. 74 fig. Clarendon Press: Oxford, 1931. Pr., $2.50.—This elementary text contains chapters on material and energy; sugar and the plant materials formed from them; nitrogenous compounds; decomposition of sugars and the liberation of energy; the protoplast; water; irritability; and growth. Each chapter contains suggestions for experimental work. A short list of reagents and their preparation is included. The book closes with a subject index.—*Oran Raber.*

OSMOSIS, PERMEABILITY, PHYSICO-CHEMICAL PHENOMENA

15475. CHENEY, GWENDOLYN M. A correlation between leaf dimensions and osmotic concentrations in chickweeds. *Proc. Roy. Soc. Victoria* 42(2): 85-91. 3 fig. 1930.—Seedlings of *Stellaria media* and *Cerastium vulgatum* were grown in soil watered with solutions of varying concentrations. As the concentration of the salt was increased the leaf dimensions increased. The highest concentration of NaCl which could be added was 1/500 for *Cerastium*, and 1/100 for *Stellaria*. The number of stomata per sq. mm. of leaf surface of *Stellaria* diminished in high concentrations of NaCl. This was not merely a mechanical effect due to increase in leaf surface, because the total number of stomata was also reduced, thus reducing transpiration.—*Author's summary.*

15476. DAMON, E. B., and W. J. V. OSTERHOUT. The concentration effect with Valonia: potential differences with concentrated and diluted sea water. *Jour. Gen. Physiol.* 13(4): 445-457. 1930.—Electrical connection with the vacuole of a cell of *Valonia macrophysa* is established by impaling the cell on a fine glass capillary filled with artificial sap; on standing, the protoplasm becomes sealed to the glass. The P. D. between the interior of the cell and concentrated sea water (up to 1.5 times the strength of sea water) or diluted sea water (down to 0.2 times the strength of sea water) made isotonic with glycerol, is given by the equation: $P.D. = P.D._{s.w.} + \frac{2}{3} RT/F \ ln$ 1/concn. relative to that of *s.w.*, where $P.D._{s.w.}$ is the value (5-8.5 mv.) observed with natural sea water. The sign is that of the interior of the cell. While these P.D.'s may be stable for some hrs., brief exposure to very concentrated or very dilute sea water, or to hypotonic solutions, leads to reversal of the sign of the P.D. The concentration effect is due mainly to the NaCl in the sea water. It is suggested that the factor of $\frac{2}{3}$ in the formula represents the difference betwen the transfer numbers of Cl^- and Na^+ in the protoplasm; in this case, it is necessary to assume for Cl^- a mobility 5 times as great as that of Na^+.—*E. B. Damon.*

15477. HARPEN, NICHOLAAS HENDRIK van. The electrometric determination of the hydrogen ion concentration in the latex of Hevea brasiliensis and its applicability to technical problems. 459p. 41 fig. Varekamp & Co.: Medan, 1931.—Much of this book consists of a review of the physical chemistry of latex with especial reference to that dealing with coagulation and pH. A method of measurement of the pH by the quinhydrone electrode is described together with a micro-method for quinhydrone. Latex from normal trees had a pH of 6.87-7.07 while that from trees in unfavorable conditions was more acid (pH 6.63). Latex is buffered against change by dilution. Changes is acidity of the rubber dispersion by adsorption of H ions on the particle surface in different concentrations of coagulants and with different latex concentrations are determined. The pH of maximum flocculation lies at 5.05 while maximum coagulation is at 4.77. Boundary limits of the coagulation and flocculation zones were determined for latices of varied rubber content. The 1st liquid stage and flocculation are at a higher pH than normal in boiled or in centrifuged latex. With underlatex and formalin latex this boundary is at higher acidity values. In centrifuged cream latex, the 2nd liquid, and 2nd coagulation stages are at higher pH values. Auto-acidification, due to bacteria, is the chief cause of variation of the pH of normal latex. Mineral acids used as coagulants hinder auto-acidification, while organic coagulants in small quantities aid acidification but in large amounts hinder it and are thus less constant. Latex is a "pseudo-lyophilic dispersion," due to the incomplete protein coating on the surface of the particles. This protein causes flocculation but not coagulation. Normal latex follows the Freundlich adsorption isotherm closely, but boiled or formalin latex absorbs coagulants to a lesser degree. Gelation after discharge and dehydration is explained by the activity of re-hydrating substances. Sterols which flocculate at pH 3.02 were extracted from latex and, if added to de-hydrated latex, brought about gel formation at the normal pH. These seem to be carried in the latex as the resin globules of Frey-Wijssling and hence explain the spontaneous gel formation of underlatex and difficult gel formation of cream of centrifuged latex. Ammonia or formalin hinder gelation by the hydratant. The activity of other *Hevea* spp. in causing gelation of boiled *H. brasiliensis* latex corresponded to the size of their resin particles in the following order: *H. collina* > *H. guyanensis* > *H. spruceana*. These sterols have catalytic influence as shown by the close comparison between their action and that of the hypothetical coalase and hence they are considered the natural hydratant present in the latex. The flocculation and coagulation stages are independent, the latter only occurring at a certain acidity in the presence of enough of the hydratant. Methods of electrometric titration are described.—*L. S. Moyer.*

15478. HARRIS, JAMES ARTHUR, and HENRY ATHERTON LEE. The properties of the tissue fluids of sugar cane in their possible relation to drought re-

sistance. *Hawaiian Planters' Rec.* 34(2): 167-177. 1930.—In a series of averages (for leaves and stems) Uba stands first in freezing point depression and osmotic concentration, and is followed by Yellow Caledonia and Badila, but the order of the 2 latter is reversed in the case of the determinations on leaves and stems. In both cases H 109 occupies the 4th position. Lahaina, D 1135, and Yellow Tip show the lowest values in the determinations on leaves and stems. It is concluded that this is also the order of drought resistance.—*From authors' conclusions.*

15479. LLOYD, FRANCIS E. The problem of excretion with especial reference to the contractile vacuole. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1163-1168. 1929.—Contractile vacuoles occur in the conjugating gametes and in the condensing zygote of *Spirogyra,* and they may be induced in vegetative cells by the application of suitable, strong plasmolysing agents. The relation of contractile vacuoles to the primordium in the cytoplasm is discussed with reference to the work of others. From a biophysical point of view the problem of the origin of the contractile vacuole is regarded as that of internal syneresis, and comparisons are made with models. The contractile vacuoles of *Spirogyra* arise in or from the cytoplasmic layer, and their function is to take water out of the central vacuole and expel it more rapidly than it can be taken up osmotically. It is concluded that the contractile vacuole is an excretory organ, possibly merely water-excretory, though presumably the discharged water is accompanied by substances in solution or in more or less solid condition.—*M. C. Merrill.*

15480. MONSALUD, MANUEL R. Colloid content of mill juices under normal maceration and less maceration. *Philippine Agric.* 20(1): 53-74. 1 fig. 1931.—An investigation involving 156 determinations of the colloid content of mill juices in a sugar Central by the use of the ultramicroscope cataphoresis apparatus indicated that the dye values of the charged colloid of the mill juices are a function of the quality of the ground cane. The amount of colloids of the juices from each mill appears to be related to the amount of the juice extracted by each mill. Between the normal maceration and less maceration millings, the amount of dye needed to neutralize the charged colloids in the 4th mill juice appears to be a linear function of the corrected Brix. To a certain extent, the addition of maceration water produces more colloids in the juice, but this disadvantage is not alarming, as a higher sucrose extraction results from more efficient maceration.—*M. R. Monsalud.*

15481. ROBBINS, WILLIAM J. The analogy between plant tissue and a protein. *Proc. Internat. Congr. Plant Sci., Ithaca, N. Y. 1926* 2: 1125-1138. 1 fig. 1929.—The isoelectric point of various tissues was determined by noting absorption of water, absorption of cations and anions, and the influence of tissues on the reaction of solutions in which they are placed. The isoelectric points observed are: potato tuber pH 6.0-6.4; soybean root tips pH 6.2-6.44; *Elodea* pH 5.8-6.2; *Rhizopus nigricans* near pH 5.0; *Fusarium oxysporum* pH 4.9-5.0; *Giberella saubinettii* near pH 6.2, and for *Fusarium lycopersici* pH 5.4-5.5. Potato tuber tissue dies rapidly in dilute sodium phosphate buffers at pH 4.5, which is close to the isoelectric point. If small amounts (0.00068M) of a Ca salt are added, the tissue lives for some time. Tests with potato tuber tissue and mycelium of fungi show that cations are more toxic in solutions on the alkaline side of the isoelectric point and anions are more toxic on the acid side, indicating that substances become toxic when they combine with the living constituents of the cell. Growth, spore and seed germination, infection by fungi, and staining of sections of plant tissue by dyes are also correlated with the isoelectric point.—*H. R. Kraybill.*

Biol. Sperim.* 5(4): 490-492. 1930.—The buffer action of the juice of vegetables (lettuce, cabbage) is due chiefly to dialysable acid-salt systems and much less to protein.—*M. Comel.*

15483. WILSON, A. L. Hydrogen-ion concentration in relation to the growth of onions. *Proc. Amer. Soc. Hort. Sci.* 27: 524-528. 1930(1931).—Onion plants were grown in nutrient solutions adjusted at intervals of 0.5 of a pH, from pH 3.5 to 8.0. Responses were measured in terms of total increase in fresh and dry wt. and in % of increase in fresh and dry wt. The results of 3 experiments conducted under slightly different conditions of light, length of day, and temp. indicate that onions may be expected to grow satisfactorily in nutrient solutions at pH 5.5-7.0.—*A. L. Wilson.*

WATER RELATIONS, SAP MOVEMENT

15484. ABELL, C. A., and C. R. HURSH. Positive gas and water pressure in oaks. *Science* 73(1895): 449. 1931.—Noted in *Quercus coccinea, Q. montana,* and *Q. alba.*

15485. BARRETT, A. O., and HEBER GREEN. The seasonal sap flow of Eucalyptus botryoides. *Proc. Roy. Soc. Victoria* 43(2): 241-250. 1931.—The roots of mature trees are apparently dormant during spring and summer, but begin to form white, very active roots and root hairs in early autumn. During autumn and winter, water is stored in the bark, the moisture content of living bark rising from 57 to 64% (i.e., from 132 to 178% of the dry bark), whilst the formation of new leaves is almost nil. After the irrigative period the new leaves form in a succession of flushes or waves every 3-5 weeks throughout the spring and summer. At the same time, the sugar produced by these leaves accumulates in the bark until the sugar content has increased from 1.5 to 8%. The ash content is at its minimum (3.5%) in the spring, and at its maximum (6.0%) in the autumn. It seems probable that these periods of root growth and the other peculiarities observed, so different from those of the exotic plants of colder climates, are some of the developments which have enabled eucalypts to flourish in a semi-arid climate, withstanding a summer drought, and storing up a water supply in the wet season.—*From authors' summary.*

15486. BRIERLEY, W. G. Transpiration rates in old and new canes of the Latham raspberry as measured by nontoxic dyes. *Proc. Amer. Soc. Hort. Sci.* 27: 152-157. 1 fig. 1930(1931).—In canes of approximately the same diam. at the base, dyes rose in old canes much faster than in new canes, at the height of the harvest season. In early Aug., the rates tended to become nearly equal; then the rate declined in the old canes. In the new canes the rate increased until mid-Aug. followed by a decline. The rates for the old and new canes were roughly parallel until late Sept. when the decline in the old canes became more rapid. Although the use of dyes does not give an accurate measure of transpiration rate, the method showed the old canes to be highly efficient in water conduction until early Sept.—*W. G. Brierley.*

15487. KAMP, HERBERT. Untersuchungen über Kutikularbau und kutikuläre Transpiration von Blättern. *Jahrb. Wiss. Bot.* 72(3): 403-465. 12 fig. 1930.—Leaves of about 30 sp. of mostly woody plants were tested. The stomata on all leaves were ventral. The loss of water from the detached leaves was measured gravimetrically by attaching the petioles by a thread to the arm of a specially constructed torsion balance, which was placed within a box having glass windows that could be opened and closed as desired. After determining the loss of water for the entire leaf, the ventral surface was covered with vaseline to determine the amount of loss through the cutinized dorsal surface. Leaves of plants growing both in the open and in the glasshouse were tested, likewise both sun and shade leaves. The results of the test showed that the loss of water from the sun leaves during a given period was much more than from the shade leaves of the same sp., and that the dorsal surface of the sun leaves lost much more than that of the shade leaves. In some cases the loss from the ventral surface of sun leaves was only 2 times that of the loss from the dorsal surface

(*Coffea arabica*), while in others the loss from the ventral side was 45 times that of the dorsal (*Laurus nobilis*). The thickness of the cuticle in itself did not appear to govern the amount of water which escaped through it; and the epidermal cells themselves, aside from their layer of cutin, are a factor in controlling loss of water.—*E. T. Bartholomew.*

15489. MAXIMOW, N. A. The physiological nature of drought-resistance of plants. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1169-1175. 1929.—Intensity of transpiration alone can not serve as an index of the degree of xerophytism and most of the factors forming the dry habitat increase the transpiration capacity of plants. Also no direct correlation exists between drought-resistance and the water requirement of plants, but the capacity to endure without significant injury a state of permanent wilting is the principal peculiarity of drought-resistant plants. This capacity is explained on the basis of conditions within the cells, such as increase in osmotic pressure and modifications in the protoplasm itself that increase its water-holding capacity. External changes (xeromorphism) that further affect the conservation of water are merely the manifestation of these more fundamental inner physiological changes. In the case of a typical xerophyte these physiological characteristics are thought to be inherited. Thus the problem of drought-resistance like that of cold-resistance is transferred from the domain of morphology to the field of physiology and biochemistry.—*P. D. Strausbaugh.*

15492. PAVLOV, KYRIL. Počet, velikost průduchů a ssaci sila (osmotická hodnota), jako pomůcky ke zjištění fysiologických vlastnosti zušlechtěných soret pšenice a ovsa, se zvláštnim zřetelem k resistenci vůči suchu. [Number and size of stomata and suction force as means of determining physiological properties of varieties of wheat and oats, with special reference to drought resistance.] [German abstract.] *Věstnik Českoslov. Akad. Zem.* 6(6/7): 620-626. 1930.—A great number of pure line winter and spring wheats and spring oats were examined. The suction pressure was determined by the method of Eibl-Buchinger-Meyer. Results showed, with few exceptions, that the more xerophytic and earlier varieties have shorter stomata and greater suction pressure, while the more hygrophytic and later ones have longer stomata and smaller suction pressure.—*K. Pavlov.*

MINERAL NUTRIENTS, SALT RELATIONS

15493. DAVIDSON, O. W. An application of the triangle system in determining a nutrient solution suitable for research with the peach in sand culture. *Proc. Amer. Soc. Hort. Sci.* 25: 354-358. 1928.—A nutrient solution having an osmotic pressure of 1 atmosphere and the following salt proportions: 0.01055 *M* KH_2PO_4, 0.00438 *M* $Ca(NO_3)_2$, 0.00237 *M* $MgSO_4$, and 0.0014 *M* $(NH_4)_2SO_4$ was found suitable for growing peach seedlings in sand culture. Under the seasonal environmental conditions of the greenhouse, the solution produced maximum dry wt. yields and total linear growth.—*Author's conclusions.*

15494. FREY-WYSSLING, ALB. Über die Ausscheidung der Kieselsäure in der Pflanze. *Ber. Deutsche Bot. Ges.* 48(6): 179-183. 1930.—Deposits of silica are more frequent in tropical plants than in those of the temperate zones. This correlates with the fact that, as the result of the higher soil temp. in the tropics, silicic acid is dissolved and taken into the plants with the water required for transpiration. Hence, the silica is ballast in the water and is not used in the metabolism of the plant. It is concluded that the deposition of silicic acid must be interpreted as a defecation rather than an excretion.—*A. Frey-Wyssling* (*transl. by C. J. Lyon*).

15495. FREY-WYSSLING, ALB. Vergleich zwischen der Ausscheidung von Kieselsäure und Kalziumsalzen in der Pflanze. *Ber. Deutsche Bot. Ges.* 48(6): 184-191. 1930.—Silicic acid and Ca salts are deposited in homologous tissues and tissue elements. Interchangeable occurrences of salts of silica and Ca indicate an analogous physiological significance of these deposits. The $CaCO_3$ excreted by plants can be interpreted as a defecation product. In the case of Ca-oxalate, only the Ca ion can be regarded as such, while the oxalate ion represents a metabolic product and therefore an excretion.—*A. Frey-Wyssling* (*transl. by C. J. Lyon*).

15496. LILLELAND, O. Does potassium increase the sugar content of prunes? *Proc. Amer. Soc. Hort. Sci.* 27: 15-18. 1930(1931).—Heavy applications of K salts to prune trees growing in K deficient soils increased the K content of leaves and fruit and delayed the development of leaf scorch, but did not increase the sugar content of the fruit. A survey of the K contents of leaves and fruit of prune trees, and the soil in which they grow in 14 orchards located in widely separated sections of California, failed to show any correlation between K and the sugar content of the fruit.—*O. Lilleland.*

15497. LOEW, OSCAR, und FRITZ MERKENSCHLAGER. Über die Resistenz der Maiswurzel gegen Magnesiumsalze. *Angewandte Bot.* 11(3): 268-273. 2 fig. 1929.—Seed of maize, lupine, barley, sunflower, dandelion, and lettuce were germinated in sand, then transferred to 0.1-0.5% solutions of $MgSO_4$ or $MgCl_2$. Richter's nutrient solution was used as a control. Symptoms of Mg toxicity, different for each sp., soon appeared with all plants, excepting maize, the roots usually becoming discolored, slimy, and spongy. The roots of maize remained white and the plants alive for a month or longer in 0.5% $MgSO_4$. Since maize is a Mg-rich plant, this resistance could not be due to low permeability of the roots for Mg salts. There was no microscopic evidence of precipitation of Mg salts in the cell. The protecting action of a nuclear membrane is suggested.—*F. H. Crane.*

15498. McHARGUE, J. S., and R. K. CALFEE. Effect of manganese, copper, and zinc on growth and metabolism of Aspergillus flavus and Rhizopus nigricans. *Bot. Gaz.* 91(2): 183-193. 7 fig. 1931.—Cultures of *Aspergillus* made a heavier and a more rapid growth in the medium containing certain concentrations of Mn, Cu, or Zn than in a medium free (carefully tested) from compounds of these elements. Combinations of the optimum concentrations of all 3 stimulated a greater growth than did combinations of any 2. The presence of all 3 influenced the assimilation of P, Mg, and Ca, and the production of fat. Mn, Cu, and Zn are all essential for the growth of both fungi.—*J. S. McHargue.*

15499. MOKRAGNATZ, M. Action du nickel et du cobalt sur le developpement de l'Aspergillus niger. *Bull. Soc. Chim. Biol.* 13: 61-71. 1931.—Effects were measured by determining the dry wt. of mycelium developed from spores sown in a nutrient solution to which $NiSO_4$ had been added. Increases in wt. over checks were found in all concentrations between N/500,000 and N/15,000, at which maximum wts. were attained. Wt. of mycelium decreased with concentrations of N/7500-N/5000 and growth was almost completely suppressed in N/3000 $NiSO_4$. With Co, no stimulatory effect was observed at any concentration; N/250,000 decreased growth and N/2500 wholly suppressed it. The amount of Ni absorbed by the fungus in the various cultures did not exceed 50% of that present even in the greatest dilutions.—*J. S. Caldwell.*

15500. PANTANELLI, E. Influenza della concentrazione sul meccanismo di assorbimento dei sale nelle piante. [Influence of concentration on the mechanism of salt absorption in plants.] *Archiv. Sci. Biol. [Napoli]* 12: 163-180. 4 fig. 1928.—Bean roots were immersed for

8 hrs. at 17-19° C. in single salt solutions of $CaCl_2$, NH_4NO_3, KH_2PO_4, and $MgSO_4$ at concentrations of 0.001-0.25 *M*. For the first 3 salts, cations and anions were absorbed in unequal amounts, more anions than cations being taken up. Plasmolysis occurred at about 0.1 *M*. With concentration of 0.25-1.0 *M* the 2 classes of ions were absorbed in more nearly equal amounts, the ratio approaching unity for the higher concentrations.—*T. I. Edwards.*

15501. **TIDMORE, J. W. Phosphate studies in solution cultures.** *Soil Sci.* 30(1): 13-31. 1930.—Using corn, sorghum, and tomatoes, the rate of PO_4 absorption was not directly proportional to the PO_4 concentration of the culture solution. Rate of growth increased with increasing PO_4 concentrations throughout the growing period. Maximum growth was obtained at 0.5 p.p.m. PO_4. Corn and sorghum made a very good growth at 0.2 p.p.m. PO_4, whereas tomatoes made a poor growth. Phosphate played a minor rôle as a buffer material in the plant sap. Corn absorbed PO_4 more rapidly from acid than from alkaline solutions. There was no appreciable difference in the rate of PO_4 absorption from solutions having a reaction of pH 4.0, 5.0, and 6.0.—*J. W. Tidmore.*

15502. [TUEVA, O. F.] ТУЕВА, О. Ф. Исследование над усвоением фосфорной кислоты ячменем в водной культуре. [Assimilation of phosphoric acid by barley in a water solution.] [English summary.] Известия Биологического Научно-Исследовательского Института и Биологической Станции при Пермском Государственном Университете (*Bull. Inst. Rech. Biol. et Sta. Biol. Univ. Perm*) 6(6): 261-276. 1929.—After 3, 5, 7, and 9 weeks of growth on a complete Knop's medium, plants were transferred to jars with the same medium, but deficient in P, and left there till the end of the experiment. Plants were analyzed for total P content, distribution of P in different plant organs, P content of the exudate from the plant stump, and finally their dry wt. It was found that the amount of P absorbed by the plants during the first 5 weeks of growth was sufficient for their normal development. Subsequent absorption of P diminished the dry wt. When PO_4 was present in the culture medium, it was continuously absorbed during the whole period of growth, and no migration from vegetative to reproductive organs took place. In the absence of P in the external medium, P was removed from vegetative to reproductive organs.—*G. Krotkov.*

15503. **WALLACE, T. Studies in the nutrition of fruit trees.** *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1012-1023. 1929.—Data are summarised concerning the effects of N, K, P, Ca, Mg, and S deficiencies on growth and yields of apples, gooseberries, black currants, and raspberry and strawberry plants grown in pot cultures. In addition results are given of some experiments on the effect of varying ratio of nutrient elements and on effects of acidity and alkalinity. Lack of N greatly reduced growth, blossoming, and fruit production; leaves were small, yellowish, and the apples produced were small and highly colored. Potash deficiency produced no early effect, but later in the season leaves became slightly bluish green, curled, reduced in size, and marginal areas became brown; in general such leaves abscissed prematurely. Fruit yields were somewhat decreased, but the symptoms in general are not as marked as with lack of N. P deficiency produced effects almost as severe as those caused by N deficiency. Greatly reduced foliage, growth, and fruiting resulted. Leaves developed purplish tints which later faded to a bronze color and abscissed prematurely. Root systems were reduced in amount. No pronounced differences were found where Ca was omitted, except a tendency for larger leaves and more shoot growth. Lack of Mg manifested itself in foliage peculiarities specific for each plant. In general, the leaves of all plants were blotched and dropped prematurely. Lack of S gave symptoms like those of lack of N but not nearly to the same degree. Experiments on the effect of varying ratios of N/K and K/Mg in nutrient solutions showed that the added growth made possible by further addition of elements such as N, might make an otherwise normal supply of one element inadequate.—*H. D. Chapman.*

15504. **WALLACE, T. The nutrition of fruit trees. I. Some effects of deficiencies of essential elements on fruit trees.** *Ann. Appl. Biol.* 17(3): 649-657. 1930.—See previous abstract.

15505. **WARD, RITCHIE R. A rapid colorimetric method for phosphorus determinations.** *Hawaiian Planters' Record* 34(3): 307-312. 1930.—This method depends on the blue color that is developed when P-molybdate is reduced with phenylhydrazine. The results obtained have been shown to be reproducible. An equation has been developed for calculating the % of P, as indicated by the standard method, from the results of the colorimetric method.—*From author's conclusions.*

15506. **WOLFF, L. K., und A. EMMERIE. Über das Wachstum des Aspergillus niger und den Kupfergehalt des Nährbodens.** *Biochem. Zeitschr.* 228(4/6): 443-450. 1930.—*A. niger* requires Cu for growth and spore formation. At least 0.2γ (γ=1/1000 mg.) in 250 cc. liquid is required for growth; 0.3γ for spore formation; 25γ for the formation of black spores. The latter arise most rapidly when 250γ Cu is added to 250 cc. nutrient material.—*C. Lieneman.*

PHOTOSYNTHESIS, CHLOROPHYLL

15507. **CONANT, J. B., S. E. KAMERLING, and C. C. STEELE. The allomerization of chlorophyll.** *Jour. Amer. Chem. Soc.* 53(4): 1615-1616. 1931.—When allowed to stand in alcoholic solution, the molecular change of chlorophyll (dehydrogenation of the -CHOHCO- groupings to -COCO- groups) has been observed. The dehydrogenation is brought about by atmospheric O, and the same process can be caused by chlorophyll *a* in acetone-pyridine solution by the addition of K-molybdicyanide.

15508. **EULER, HANS von, und DAGMAR RUNEHJEIM. Chemische Beiträge zur Kenntnis der Chlorophylldefekte.** *Arkiv f. Kemi, Mineralogi och Geologi* 10A (3, paper 10): 1-8. 1931.—Barley seed contain much less catalase before germination than after. Catalase content remained constant between 10 and 14 days of germination, and was the same at 17 as at 22° C. In both barley and variegated *Pelargonium zonale*, chlorotic tissues contained much less catalase than green tissues. Grains from chlorotic barley plants contained as much Mg as those from normal plants, and the chlorotic areas of variegated *Pelargonium* leaves had more total Mg than green areas.—*N. A. Pettinger.*

15509. **KUHN, R., und A. WINTERSTEIN. Über die Verbreitung des Luteins im Pflanzenreich.** *Naturwiss.* 18(34): 754. 1931.—Lutein, the pigment of egg yolk, is closely related to xanthophyll and is widely distributed in plants: in young grass, in crude chlorophyll, in most yellow flowers, and elsewhere. Lutein seems to have been confused with xanthophyll, but the 2 compounds differ in melting point and in degree of rotation of plane of polarized light in chloroform; that of xanthophyll is $[\alpha]_D = +136\text{-}192°$ and for lutein $[\alpha]_D = +70°$ or thereabouts.

15510. **RABER, ORAN. A possible relationship between hemoglobin and chlorophyll as shown by the use of liver extract.** *Science* 73(1895): 457-458. 1931.—Corn seedlings placed in a nutrient solution to which liver extract was added and then placed in the dark did not become etiolated so quickly as controls.—*Oran Raber.*

15511. **RIPPEL, AUGUST. Kritisches zur Assimilationsgleichung von J. C. Ghosh.** *Ber. Deutsch. Bot. Ges.* 47(3): 186-188. 1929.—This is a contribution to the dispute between those who would reduce biology to a series of mathematical expressions and those who are temperamentally and otherwise opposed, but it is also shown that Ghosh's formula, by omitting the many other factors concerned, does not fairly represent the process of photosynthesis. In the Ghosh formula, a term representing the speed of CO_2 splitting is the principal factor.

Results of experiments in which the CO_2 concentration is maintained uniform and the light varied, or the illumination maintained constant, and the CO_2 concentration is changed, do not bear out the Ghosh idea; for instead of the rate of CO_2 fixation increasing with the concentration, or with the illumination, the rate declines as concentration and illumination increase. This reduces the formula and its reciprocal to more or less of a contradiction of the facts. The formula is therefore too simple for correct representation of the extremely complicated process of photosynthesis.—*G. J. Peirce.*

15512. [RYZHKOV, V.] РЫЖКОВ, В. Проблема пестролистности в современной литературе. [Problem of leaf variegation in contemporary literature.] Труды по Прикладной Ботанике, Генетике и Селекции (*Bull. Appl. Bot., Gen. & Plant Breed.*) 22(5): 523-570. 1929/1930.

15513. **WHITESIDE, A. G. O. A study of the carotinoid pigments of wheat and flour with special reference to wheat varieties.** *Canada Dept. Agric. Bull.* 154. 1-33. 1931.—As determined spectrophotometrically, milled flours from spring wheat varieties grown on dry land were higher in carotin than flours milled from irrigated land wheat. Varietal differences also played a part. Test wt. per bushel and wt. per 1,000 kernels were negatively correlated with carotin concentration of flour. Protein content of wheat and ash % of flour were not so correlated. Dry and wet slick color estimations did not appear to be reliable in estimating carotin concentrations of flour. Crumb color comparisons were significantly correlated with carotin concentrations of flour. A suitable method for determining carotin concentration value of wheat which would fairly indicate that to be expected from the flour milled from it is tentatively suggested. Samples of the same variety may be expected to vary considerably in carotin concentration of the wheat and of the flour milled from it. Higher values appear to be associated with lack of plumpness as determined by test wt. per bushel measurements.—*Author's summary.*

15514. **ZECHMEISTER, LÁSZLÓ, LÁSZLÓ CHOLNOKY, és VERÁ VRABÉLY. Újabb Vizsgálatok a paprika festékéröl.** [The paprika pigment.] [German summary.] *Math. es Természettudomanyi Értesitö (Math. u. Naturwiss. Anzeiger Ungarischen Akad. Wiss.)* 45: 639-651. 1928.—Capsicum red, a pigment composed of capsanthin and carotin, was studied by the method of hydrogenation in the presence of a catalyst. Carotin ($C_{40}H_{56}$) takes up 11 molecules of H, and capsanthin takes up 9. Perhydro-capsanthin is a colorless oil, levorotatory, and of the expected molecular wt. The carotin compound agreed in molecular wt. with the Willstätter and Mieg compound. Xanthophyll and phaeophytin were also subjected to the reaction, platinum being used as the catalytic agent. On the basis of the above findings, some comments are offered on the structure of carotinoid pigments. Partial hydrogenation should show to what degree there is a series of double-linked compounds of the Kuhn and Winterstein types. The optical activity is important in examining the structure. Perhydro-carotin is inactive, while the corresponding capsanthin derivative shows a levo-rotation comparable to an O-containing ring compound ($C_{34}H_{66}O_2$). The natural reddening of paprika fruits is an oxidation process and does not occur in an atmosphere of CO_2. The capsicum red pigment does not arise from the chlorophyll complex, but from a colorless precursor.—*Authors' summary (transl. by O. E. Street).*

BIOCHEMISTRY, METABOLISM (GENERAL)

15515. **ALLEN, F. W. The influence of ethylene gas treatment upon the coloring and ripening of apples and pears.** *Proc. Amer. Soc. Hort. Sci.* 27: 43-50. 1930(1931). —Although individual samples did not always show consistent results, Gravenstein apples and several varieties of winter pears exposed to ethylene gas (1:1000) for 4-10 days were usually yellower and softer after a given period than were untreated samples. This difference was most marked in early picked fruit. The treated apples had slightly more reducing sugars and less acid. The ethylene treatment, however, failed to influence the sugar or acid content of the pears.—*F. W. Allen.*

The constitutions of angustione and dehydroangustione. Note on the parachors of angustione and dehydroangustione, by OWEN JOHN EVANS and FREDERICK GEORGE SOPER.** *Jour. Chem. Soc.* [*London*] 1931(Feb.): 286-294. 1931.

15522. **CLAASSEN, H. Das Wachstum der Hefe und die Zunahme ihrer Bestandteile bei dem Lufthefeverfahren.** *Biochem. Zeitschr.* 228(1/3): 154-162. 1930.—Hourly determinations of the increase in dry matter, protein, N-free substances, and ash of yeast in fermentation experiments showed that protein formation was greatest when the wort contained sugar and easily-assimilable N compounds, especially ammoniacal N. N-free constituents were synthesized most when the wort contained amino acids, alcohol, and N-free organic acids but no sugars, in the final hrs. of fermentation. The addition of limited amounts of ammoniacal N to worts containing sufficient assimilable organic N-containing materials for yeast growth did not increase the yield of yeast dry matter, but caused the yeast to form more protein and less N-free substances.—*Author's summary (transl. by N. A. Pettinger).*

15523. **DENNY, F. E. The twin-leaf method of studying changes in leaves.** *Amer. Jour. Bot.* 17(8): 818-841. 1930.—Because of the objections that have been made to the Sachs half-leaf method of selecting samples of leaves to determine the changes that take place during a given time interval, attention was turned to the possibility of using the paired leaves of sp. having opposite leaves or leaflets, the plan being to take one leaf of the pair at the beginning of the period and the other at the end. The variation in the wts. of opposite leaves of such pairs was determined for a number of sp., special attention being given to *Salvia splendens.* Here the

error involved in the assumption that the wts. of opposite leaves were equal was about 1% on a composite sample of 25 leaves and about 2% on a sample of 9. The method was applied to a study of the changes in fresh wt., dry wt., water content, starch, soluble solids, insoluble N, etc. during a 24 hr. interval, samples being taken each 2.5-4 hrs.—*F. E. Denny.*

Sci.* 36: 233-239. 1929 (1931).—Pollen of 15 sp. of spring-flowering trees was examined morphologically and tested for starch, sugars, fats, and protein. All sp. contained starch; sugar was found in pollen of *Salix longifolia* and *Ulmus fulva;* none showed fats; and pollen of Betulaceae showed no protein.—*H. S. Conard.*

15527. **HERISSEY, H., et J. CHEYMOL. Sur le vicioside.** *Bull. Soc. Chim. Biol.* 13: 29-34. 1931.—Rittthausen isolated vicine from seed of *Vicia sativa* in 1870. He believed that the sugars resulting from hydrolysis with dilute H_2SO_4 consisted of glucose and galactose. The authors were able to identify only d-glucose in the products of hydrolysis; no trace of galactose was found. —*J. S. Caldwell.*

15528. **HILL, R., and D. KEILIN. The porphyrin of component c of cytochrome and its relationship to other porphyrins.** *Proc. Roy. Soc. [London] B* 107 (751): 286-292. 1 fig. 1930.—Two different porphyrins can be prepared from the unmodified cytochrome *c* obtained from bakers' yeast. Under the action of HBr and acetic acid, cytochrome *c* yields a hematoporphyrin which is indistinguishable from hematoporphyrin prepared in the same way from the ordinary hematin. Both show the same solubilities in ether and acetic acids, and the same absorption spectra in ether and in HCl. Both when reunited with Fe combine with various N compounds or with native globin and give respectively hemochromogens or hemoglobins with similar absorption spectra. Both hematoporphyrins (prepared from cytochrome *c* and from ordinary hematin) can be easily converted into protoporphyrin. This conversion can be accomplished by (a) heating the hematoporphyrin in vacuo; (b) heating the corresponding hematohematin in vacuo; or (c) by heating the hematohematin in acetic acid in a sealed tube. The fact that hematoporphyrin obtained from *c* can be converted into protoporphyrin gives an additional support to Keilin's proposal as to the origin of cytochrome, namely, that it is derived from the protohematin present in cells. Under the action of HCl, in the presence of a reducer such as SO_2, cytochrome *c* gives another porphyrin which can be considered as the unmodified porphyrin *c* of this compound. The absorption bands of this porphyrin occupy an intermediate position between those of hemato- and protoporphyrin, lying, however, nearer those of the former. This porphyrin when recombined with Fe and a N compound such as pyridine gives a hemochromogen indistinguishable from that of component *c* of cytochrome dissolved in aqueous pyridine. This unmodified porphyrin is insoluble either in ether and acetic acid or in chloroform, and its absorption spectrum can be measured either in acid or in pyridine. The porphyrin *c* on long standing in HCl in the presence of SO_2 gradually becomes transformed into ordinary hematoporphyrin. —*Authors' summary.*

15529. **KAKESITA, KINZIRO. Preliminary report on the study of artificial removal of astringency in the kaki.** *Proc. Imp. Acad. [Tokyo]* 6 (10): 397-398. 1930.

15530. **LAGATU, H., et L. MAUME. Le diagnostic foliaire et son degré de sécurité.** *Compt. Rend. Acad. Sci. [Paris]* 188 (16): 1062-1064. 1929.—From work on grape and potato leaves, it is concluded that a chemical analysis of the leaves can be used to determine with some degree of accuracy the physiological activity of the plant, the soil medium being considered homogeneous. The importance of this fact in agricultural experiments is stressed.

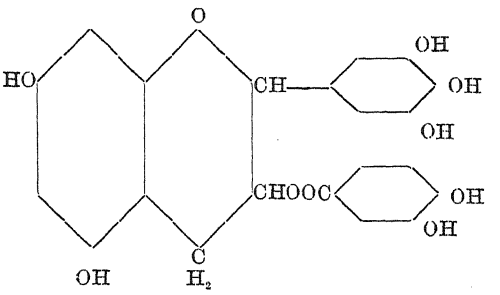
15548. **TSUJIMURA, MICHIYO.** On the constitution of tea tannin. *Sci. Papers Inst. Phys. & Chem. Res.* [*Tokyo*] 15(293): 155-159. 1 pl. 1931.—That tea tannin isolated from green tea is the gallic acid ester of tea catechin and has the formula



is supported by the fact that the methyl derivative of tea tannin has the formula $C_{22}H_{11}O_3(OHC_3)_7$. Synthesis of heptamethyl tea tannin by combining tea catechin with the chloride of trimethyl gallic acid in the presence of quinoline, yielded a compound having the same absorption spectrum as the heptamethyl tea tannin produced by methylation. This is believed to constitute decisive proof of the correctness of the assumed constitution of tea tannin.

15549. **VICKERY, HUBERT BRADFORD, and GEORGE W. PUCHER.** The chemical changes that occur during the curing of tobacco leaves. *Science* 73(1893): 397-399. 1931.—Five 50-kgm. lots of leaves (8th-11th leaf) were picked from plants of Connecticut shade grown tobacco on the same day. One lot was immediately extracted with boiling water; the other 4 were cured in the customary manner. Lots were removed at the expiration of 12 days (yellow stage), 18 days (brown stage), and 51 days (fully cured). From each lot a representative sample was dried and the remainder was exhaustively extracted with boiling water. The extracts, press cake, and dry leaf samples were analysed for total solids, ash, crude fiber, soluble carbohydrates, ether extractives, and total, ammonia, amide, amino, and nitrate N. After completion of the curing process, 96.4% of the water originally present in the fresh leaf had evaporated, and 19.8% of the organic solids of the leaf disappeared; about ½ of this loss had its origin in protein. During the same period 39% of the ether soluble extractives, 81% of the soluble carbohydrates, and 38 gm. of N, of which only 4 gm. could be accounted for as nicotine N, disappeared. Far reaching chemical changes set in very shortly after leaves are detached, since ¾ of the loss of water and of soluble carbohydrates, and more than ½ of the loss of organic solids and of ether soluble constituents, occurred during the first 12 days. During this same period at least ½ of the potential amino N of the protein that underwent enzymatic hydrolysis was converted into amino and amide N, indicating that the essential sequence of reactions was protein N → amino N → ammonia N → amide N.—*G. W. Pucher.*

15550. **WIERTELAK, JAN.** The chemical composition of wood of Trochodendron aralioides. *Jour. Forest.* 29(1): 64-67. 1931.—The chemical composition of wood of this evergreen tree, which is native to Formosa and Japan and which has a wood structure intermediate between that of an angiosperm and that of a gymnosperm in that the rays are multiseriate and vessels are entirely absent, is given in a table. The high pentosan content (20.46%); the high acetic acid content (7.42%); and the deep red color obtained by the Mäule test, show that the wood conforms fully to the hardwood type.—*P. C Wakeley.*

15551. **YANOVSKY, E., and R. M. KINGSBURY.** New sources of inulin. *Jour. Amer. Chem. Soc.* 53(4): 1597-1601. 1931.—Inulin was prepared from camas roots (*Quamasia quamash*) bulbs of *Allium nuttallii*, and roots of *Balsamorrhiza sagittata*. The specific rotation of the preparations ranged from −28° to −33°.

15552. YOKOYAMA, YOSHIKUNI, and BUNSUKE SUZUKI. Soy bean lecithins. II. Lecithins of α-series. *Proc. Imp. Acad.* [*Tokyo*] 7(1): 12-14. 1931.—Chemical composition and physical properties of palmito-linoleo-α-lecithin, oleo-linoleo-α-lecithin, dioleo-α-lecithin, and dilinoleo-α-lecithin are discussed.

15553. YOSHIDA, TOKUTARO. Chemical studies on the ether-soluble constituents of mulberry leaves. Pt. I. Phytosterol. [In Japanese, with English summary.] *Bull. Imp. Sericult. Exp. Sta.* 8(1): 35-42. 1 pl. 1930.—Phytosterol was isolated from the ether extract in pure crystalline form. The amount, determined gravimetrically by precipitation of the digitonin-phytosterol, was 0.04-0.07% in fresh mulberry leaves; 0.16-0.20% in dried leaves; 2.30-4.00% in the ether extract.

BIOCHEMISTRY, METABOLISM (ENZYMES, FERMENTATION)

15554. ABDERHALDEN, EMIL, und WALTER SCHAIRER. Zum Problem der spezifischen Wirkung der Tyrosinase. *Fermentforsch.* 12(3): 329-332. 1931.—Tyrosinase prepared from dried fungi or potato peelings does not affect *m*-tyrosin but does produce a reddish yellow color and dark precipitate from *o*-tyrosin. It produces a strong red color with *p*-tyrosin, adrenalin, 3,4-dioxyphenylalanin, and 2 aminotyrosin. A similar enzyme preparation from *Russula delica* gives comparable reactions but in addition a red color with *m*-tyrosin. Tyrosinase also reacts positively with *o*- and *m*-cresol; tyrosin-containing dipeptides and corresponding halogen acyl compounds; β-[3,5-diiodo-4(4′-hydroxy-phenoxy)-phenyl]-α-aminopropionic acid; 2,5 diiodo-, and 2,5 dibrom-tyrosin; and *l*-tryptophane but not thyroxin, *d*- or *l*-ephedrin, or *d*-alanyl-*l*-tryptophane. While it is possible with well-purified enzyme preparations to secure concordant results, it is conceivable that some tyrosinase solutions contain interfering substances or other phenolases which account for the observed results. It is also possible, as in the case of positive reaction with phenyl-β-aminopropionic acid, that a subsidiary enzyme oxidizes the benzene nucleus and thereby creates conditions for the action of tyrosinase.—*E. McCoy.*

15555. CAMP, W. H. Catalase activity and sex in plants. *Amer. Jour. Bot.* 16(4): 221-224. 1929.—The catalase activity of various tissues from 12 sp. of plants having bisporangiate, monosporangiate, or dioecious types of inflorescences [*Morus rubra* L., *Pinus nigra* Arnold, *Acer platanoides* L., *Aesculus glabra* Willd., *Zea mays* L., *Ricinus communis* L., *Alnus alnus* (L.) Britton, *Carica papaya* L., *Arisaema triphyllum* (L.) Torr., *Arisaema dracontium* L., *Alocasia odora* (Roxb.) C. Koch., and *Yucca filamentosa* L.] was compared with the sexual expression. In all sp. examined, tissues related to the ♂ structures, either purely vegetative or floral, showed a distinctly greater catalase activity than tissues related to the ♀ structures of the same sp. Also, in general, floral structures showed a greater difference than vegetative parts.—*Author's summary.*

15556. CHARMANDARIAN, M. O. Zur Methodik der Katalasebestimmung im Gerstenmalz. I. *Biochem. Zeitschr.* 204(4/6): 389-396. 1929.—The catalase of malt, by prolonged extraction, loses its capacity to decompose H_2O_2. The prolonged extraction does not influence the pH of the medium, which excludes the origin of new factors which might affect the activity of the catalase. The extraction process of the malt may be conceived as a peptization of the colloid-ferment, which requires much time (depending upon the size of the malt particles) and parallels the reverse process of coagulation, which brings about a marked reduction of the decomposing capacity of the catalase. The ferment is thought to exist in a polydispersed condition, in which it is capable of various catalytic reactions. According to the degree of dispersion of the colloid (ferment) its capacity for one reaction may increase, for another, diminish.—*H. F. Bergman.*

15557. CYNBERG, D. I. Recherches sur la catalase. II. Recherches sur la transformation de la matière chez le Raphanus. [Thèse No. 669. Univ. Genève.] 35p. 3 fig. Société Anonyme: Genève, 1928.—Results of measurement of catalase activity of leaves and seed of chrysanthemums, and effect of various chemicals thereon, both in light and in darkness, are similar to those of previous workers. Part II reports preliminary analysis of radish seed.—*R. W. Thatcher.*

15558. ENGLIS, D. T., and LOUIS GERBER. A study of diastase activity in plants: the effect of phosphates in the soil media. *Soil Sci.* 28(3): 221-223. 1929.—Soybeans were grown in pot cultures with different amounts of acid phosphate fertilizers. Although the dry wt. and P absorbed increased markedly with increasing applications of the fertilizer, the changes in diastase activity were slight for moderate amounts. With large amounts the activity seemed to fall off even though the dry wt. and P taken in still increased. With rock phosphate no significant differences in any respects were observed between the untreated and treated pots.—*Authors' summary.*

15559. HARDING, PAUL L. Relation of catalase activity to temperature, respiration and nitrogen fertilization of Grimes Golden apples. *Proc. Amer. Soc. Hort. Sci.* 27: 37-42. 3 fig. 1930(1931).—With both immediate and deferred storage at 30° and 36° F. and with continuous storage at 50° F., Grimes Golden apples from nitrate-treated plots were consistently higher in catalase activity. In deferred storage fruit, just prior to the appearance of soggy breakdown, high catalase activity was registered with no corresponding increase in respiratory intensity. Respiration was not so sensitive an indicator of the approach of this disorder as was catalase activity, which indicated early in the storage season whenever breakdown was to occur.—*P. L. Harding.*

15560. KARMARKAR, DATTATREYA VISHNU, and VINAYAK NARAYAN PATWARDHAN. Amylase from wheat. *Jour. Indian Inst. Sci.* 13A(13): 159-164. 7 fig. 1930.—Amylase from germinated wheat is more active than the corresponding barley enzyme. The optimum temp. for the action of wheat-amylase is 49°-58°. If heated 1 hr. at 160°, the dry enzyme is completely inactivated. The optimum reaction is pH 4.6. The enzyme is inactivated on prolonged dialysis in collodion bags. The activity is not regenerated by adding various salts and amino-acids, which (neutral) have no influence on the activity of wheat-amylase. Pepsin inactivates the enzyme, but trypsin and papain do not.—*Authors' summary.*

15561. MEYERHOF, O., und KEN IWASAKI. Über Beeinflussung der Gärungsgrösse und des Oxydationsquotienten der Hefe. *Biochem. Zeitschr.* 226(1/3): 16-31. 1930.—The influence of the Z-factor discovered by Euler in yeast extract and in beerwort was studied on the fermentation of live yeast in N and O. In optimum concentration, the anaerobic fermentation by *S. ludwigii* is 100-200% greater than in sugar phosphate solution; with compressed yeast it is 100%. The effect of the yeast extract is detectable in a 1000-1 dilution. Simultaneously, the oxidation quotient of the fermentation is increased considerably although the respiration is unchanged. The activity increases with the temp.; it is scarcely detectable at 10°. The increase is independent of the sugar concentration. The Z-factor is present in the live yeast and is given off to the medium, especially in the presence of sugar and O. Therefore in a yeast suspension shaken several hours in a sugar phosphate solution, the anaerobic fermentation increases considerably without increase of the dry wt., and the supernatant liquor centrifuged from such yeast increases the fermentation of added yeast. The concentration of the Z-factor in yeast is greater than in yeast water, which indicates that it is continuously produced and given off to the medium by the yeast.—*Authors' summary (transl. by L. Soppeland-Butcher).*

15562. NELSON, J. M., and A. H. PALMER. Diffusion of yeast invertase through collodion membranes. *Jour. Biol. Chem.* 87(1): 1-6. 1930.—Crude yeast invertase solutions were dialysed in collodion bags, at

different pH values. Results show that more invertase passes through the collodion membrane at pH 6.7 than at pH 4.6, while the loss of enzyme during dialysis is greater at the latter pH.—*Authors' summary.*

15565. **POLAK, F., und A. TYCHOWSKI. Beiträge zur Chemie der Stärke, vom diastatischen Standpunkt aus betrachtet.** *Biochem. Zeitschr.* 214(1/3): 216-228. 1929.—Amylose was prepared according to the method of Sherman and Baker and the action of α and β diastases was found to be as outlined by Syniewski. It was not possible to obtain pure amylopectin, but by allowing β diastase to act on starch for a short time and then precipitating with alcohol a product was obtained which when dissolved with varying amounts of heating yielded in solution preparations which on hydrolysis with α diastase gave different amounts of maltose. This indicated that the ratio between amylopectin and amylose had been changed.—*L. P. Miller.*

15566. **ROSENBLATT, M., und A. MARCH. Über den Einfluss katalytischer Elemente auf die alkoholische Gärung. II.** *Biochem. Zeitschr.* 226(4/6): 404-414. 1930.—Under the given conditions (no nutrients for the yeast) no metal accelerates fermentation; apparently on a nutrient substrate the metals promote only the growth of the yeast; by the increase in the latter, fermentation of sugar is also promoted. On the fermentation itself these elements apparently have no stimulating influence. Alcoholic fermentation can proceed in presence of very high concentrations of metal; these concentrations exceed by far such as will cause complete inhibition of yeast development (e.g., Co about 100 times). The order of the metals in their inhibiting action on zymase (within the yeast cells) does not coincide with the order determined for their simultaneous action on yeast development and fermentation on a nutrient substrate. Ni is the most poisonous to both actions; next, so far as inhibition of zymase is concerned, comes Fe, then Co and Mn (equal). Of especial interest is the difference in action of Co and Ni on zymase; e.g., with a concentration of 3% of metal 10.5% of sugar is fermented in presence of Ni and 79.2% in presence of Co (% compared with controls). An analogous difference in action of the 2 metals on pepsin has been observed by Tshuchihashi. Salts of Fe^{+++} are more active paralysors than salts of Fe^{++}; at 0.2% concentration the former is 5.5 times as active as the latter.—*W. E. Thrun.*

BIOCHEMISTRY, METABOLISM (RESPIRATION, OXIDATION)

15569. **ELEMA, B., and A. C. SANDERS. Studies on the oxidation-reduction of pyocyanine. Part 1. The biochemical preparation of pyocyanine.** *Rec. Trav. Chim. Pays-Bas* 50(7/8): 796-806. 1931.—A method is described for the biochemical preparation of the pure hydrochloride of pyocyanine in high yield. As much as 260 mgm. of this salt has been obtained from a litre of a liquid culture of *Pseudomonas pyocyanea.*—*Authors' summary.*

15570. **GERHART, ARTHUR R. Respiration in strawberry fruits.** *Bot. Gaz.* 89(2): 40-66. 4 fig. 1930.—An exceedingly sensitive respirometer is described, by which the rate of respiration of a single strawberry over ½ min. can easily be measured. The amount of O used by the Missionary strawberry at 5-40°C. was determined, and amounts of O required by strawberries during shipment in carload lots were calculated. The maximum initial rate occurs at 36.5°C. The temp. coefficient for the respiration of the Missionary strawberry is 2.5 below 25°C. Strawberries are very effectively protected from water loss in dry air and have a very constant water content (89.5-90%). The Gibson strawberry, northern grown, has a much higher rate of respiration at low temp. than the Missionary, which is southern grown. Acid content declines as strawberries ripen. The respiratory ratio is greater than 1. Ethylene gas has no effect in ripening strawberries.—*A. R. Gerhart.*

15571. **HUMFELD, HARRY. A method for measuring carbon dioxide evolution from soil.** *Soil Sci.* 30(1): 1-10. 1 pl. 1930.—The method described is suitable in greenhouse plots and under field conditions. The apparatus consists essentially of a galvanized iron collecting box, a suction device and an absorption train. From the collecting box the air is removed by suction as it diffuses from the soil, and is carried into an absorbing unit. The absorption train consists of 4 bottles; the 1st and 4th are empty to serve as safeguards; the 2nd and 3rd are filled with 0.16 *N* KOH. A suitable rate of flow is about 10 l. of gas per hr. The KOH solutions are titrated with HCl after the addition of an excess of $CaCl_2$. Corn and soy beans turned under as green manure give a marked increase in CO_2 evolution over that of fallow soil. Moisture conditions play an important part in each case. Rainfall is followed by a marked increase in evolution of CO_2, if the H_2O of the soil is below optimum.—*H. Humfeld.*

15572. **KUSNETZOW, S. J. The dependence of the oxidizing fermentations from the oxidation reduction potential of the external medium.** *Zentralbl. Bakt. II. Abt.* 83(1/7): 37-52. 1 fig. 1931.—In cultures of *Aspergillus niger,* made in Winogradsky flasks with a layer of liquid of 1-15 cm., thus seemingly in strongly aerobic conditions, strongly anaerobic conditions are created under the mycelium; rH falls to 15. In connection with this, a formation of citric acid is also observed, when rH falls below 17. If more aerobic conditions be created for the development of the fungus, and if one succeeds in maintaining the rH of the nutritive medium above 17 during the whole time the mycelium develops, no formation of citric acid is observed in the cultures. If, by placing the cultures in an atmosphere of N, the rH be lowered to 12.8-14, alcohol begins to form in the cultures. If the mycelium be placed in an atmosphere of H, when the rH in the cultures falls to 2, the formation of citric acid is no longer observed.—*Author's summary.*

GROWTH, DEVELOPMENT, REPRODUCTION

15573. **DENNY, F. E. The excitation of buds under external stimulus.** *Rept. & Proc. Internat. Hort. Congr. London* 9: 77-82. 1930.

15574. GOEBEL, K., und W. SANDT. Untersuchungen an Luftwurzeln. [In: *Bot. Abhandlungen.* Heft. 17.] 124p. 6 pl., 9 fig. Gustav Fischer: Jena, 1930. Pr. 12 M. —Investigations carried out upon the epiphytes in the Münich glasshouses showed that while growing in air, the growing region of the root was exceptionally long and therefore the daily increment of growth was considerable. Temp. and moisture are the external influences which most influence the growth. Although the roots of *Cissus quadrangularis* L. were strongly positively geotropic, those of *C. velutinus, Vitis repens,* and *V. pterophora* were very little, if at all, influenced by gravity. The normal direction of growth of these air roots is downwards, but at an angle, not vertically. Although branch root primordia might be present on these air roots, their further development was usually inhibited by the vigorous growth of the main root. When the latter reached the soil, the growing zone was reduced to normal dimensions, the daily increment of growth reduced accordingly, and the branch roots grew out vigorously. Growth of the main root often ceased if the root was led into water, although branch roots then developed from it. The anatomical differences between the region of the root formed in air and in soil are described.—*J. H. Priestley.*

15575. HITCHCOCK, A. E., and P. W. ZIMMERMAN. Variation in rooting response of cuttings placed in media in different P_H value. *Proc. Amer. Soc. Hort. Sci.* 23: 383-390. 2 fig. 1926.—*Azalea amoena* cuttings rooted better in acid peat moss than in sand. Privet cuttings rooted well in sand, but poorly in acid peat moss. Both azalea and privet cuttings rooted well in a mixture by volume of half sand and half acid peat moss. Considerable variation in rooting response resulted when both azalea and privet cuttings were placed in neutralized or neutral leached peat moss. Wet acid peat moss hindered callus formation in both azalea and privet cuttings, whereas sand, neutralized peat moss, and neutral leached peat moss, favored callus formation.—*Authors' summary.*

15576. HUTCHINGS, G. C., and J. A. LARSEN. Stimulation of root growth on cuttings from hardwood forest trees. *Proc. Iowa Acad. Sci.* 36: 191-200. 1929 (1931).—Cuttings of green ash, basswood, white oak, soft maple, butternut, slippery elm, and Carolina poplar were planted in sand in the greenhouse, and in mixtures of sphagnum and sand. Treatments were with 0.01 M $KMnO_4$, 1/10,000 acetic acid, 5% sucrose, and 25% thiourea. Negative results followed sucrose and thiourea, and basswood and white oak failed to root under any kind of treatment. —*H. S. Conard.*

15577. LAIBACH, F. Ectogenesis in plants. Methods and genetic possibilities of propagating embryos otherwise dying in the seed. *Jour. Heredity* 20 (5): 200-208. 9 fig. 1929.—Embryos from *Linum* hybrids, which usually produced only defective seed, were removed from the plant when about 1½ mm. long and grown on cotton moistened with sterile 10-15% cane-sugar. These embryos matured and were later germinated on moist blotting paper and successfully cultured.—*L. M. Dickerson.*

15578. LIBATIQUE, PABLO P. Comparative development of roots of rice plants grown in pots containing ammonium sulfate fertilizers of different amounts. *Philippine Agric.* 20 (2): 121-137. 1 pl., 2 fig. 1931.—$(NH_4)_2SO_4$, when used in moderate amounts, tended to promote growth and development of the roots of rice plants. When used in larger amounts, it tended to retard root development, especially in mature plants. Rice plants supplied with $(NH_4)_2SO_4$ produced more but shorter roots than the unfertilized plants, which had relatively few but characteristically long roots. The production of top and the intensity of greening of the leaves were also favorably influenced by an increase in the application of the fertilizer, but root development was poor. The anatomical structures of the roots of the rice plant did not appear to be materially affected by the rate of application of the fertilizer.—*M. Manresa.*

15579. LILLELAND, O. Growth study of the apricot fruit. *Proc. Amer. Soc. Hort. Sci.* 27: 237-245. 2 fig. 1930 (1931).—Diameter and other measurements of the apricot fruit over a period of 5 yrs. were made in conjunction with fruit thinning studies. The growth of the fruit can be divided into 3 periods: one of rapid growth; one in which the rate of growth is distinctly depressed; and one in which the rapid rate is resumed. While the extent of these periods is quite uniform, the growth made during any one period varies markedly from season to season. Data on the development of the flesh endocarp and kernel are included.—*O. Lilleland.*

15585. SCHAFFNER, JOHN H. The fluctuation curve of sex reversal in staminate hemp plants induced by photoperiodicity. *Amer. Jour. Bot.* 18 (6): 424-430. 1931.—In order to study the relation of length of daylight to sex reversal of the ♂ plants in a normally purely dioecious variety of *Cannabis sativa* bimonthly plantings were made in the greenhouse July 15–May 15. A perfect fluctuation curve was developed, ranging from zero reversal for the July 15, May 1, and May 15 plantings to 100% reversal for the Nov. 1 and Nov. 15 plantings. There are no super-males in respect to reversal, since every ♂ plant can be caused to express femaleness. The degrees of readiness or difficulty of reversal shown by different individuals are to be ascribed to degrees of differentiation, both physiological and morphological, which the individuals have attained. The determination of sex in the hemp is not caused by an allosome differential, but these chromosomes must be assumed to play a passive rôle. Determination is brought about through differential physiological states developed in gradients in both the egg and the vegetative body.—*J. H. Schaffner.*

15586. SCHAFFNER, JOHN H. Sex reversal and the experimental production of neutral tassels in Zea mays.

Bot. Gaz. 90(3): 279-298. 4 fig. 1930.—The experiments here reported establish the fact that completely neutral, vestigial tassels can be developed at will in *Zea mays* by the simple control of environmental conditions, and that the natural photoperiodic gradient extending from Aug. to Nov. will sometimes produce 40% or more of neutral tassels in a population. With proper photoperiodicity, 7 general types of tassels can be developed: 3 of pure expression—staminate (♂), carpellate (♀), and vestigial (neuter); and 4 sex mosaics—staminate-neuter, carpellate-neuter, staminate-carpellate, and staminate-carpellate-neuter. With the decreasing photoperiodicity of autumn, femaleness is only expressed at the base of the tassel and the tip is always neuter, the staminate expression occurring in the middle region. With the increasing photoperiodicity of winter and early spring, femaleness may also be expressed at the tip of the tassel and its branches, or sometimes in such a way as to form a complex mosaic with carpellate spikelets scattered among the staminate ones. Experiments with highly inbred varieties show that pure lines react to changed photoperiodicity in the same way as commercial heterozygous varieties, giving rise to complete sex reversals, neutral vestigial tassels, and all the possible types of sex mosaics, as also extreme fluctuation series between members of a plot and fluctuation between successive plots developed in light periods of different lengths. ♂ expression can be suppressed completely in the monoecious *Zea mays* when it is grown in a decreasing photoperiodic environment of suitable length. Entire plots of individuals can be developed without the appearance of a single stamen. The diversity of sexual expression obtained is absolutely due to the diversity of physiological conditions produced through the diversity of environments, and has nothing to do in general with any diversity of hereditary factors which might be present in the different individuals of a given plot, since pure lines show just as extreme fluctuation in sex reaction as heterozygous lines. The specific sex condition developed is not dependent on any balance of sex-determining or sex-producing genes. It is evident that genetic experiments involving sex conditions are of no value unless the reactions obtained are interpreted in the light of ecological conditions present.—*Author's summary.*

15587. **SCHOPFER, WILLIAM H. Recherches sur la sexualité des champignons. Le problème de la biochimie comparée du sexe.** 183p. 11 pl., 25 fig. Imprimerie Jent, S. A.: Genève; also in *Soc. Bot. Genève. 2me Sér.* 20(1): 149-323. 1928.—Part I is a survey of literature published since 1910; Part II deals with original investigations on *Mucor hiemalis*, chapter 1 being devoted to "Conditions for zygospore formation (66 p.), chapter 2 to "Biochemical sexual dimorphism" (29 p.), and chapter 3 to "Studies on carotin" (22 p.). The bibliography contains 268 references. The author has demonstrated the influence of the nutritive substratum on the production of zygospores and concludes that the reproductive phenomenon must be considered a function of the vegetative phenomena. Using Coons' medium with 1.5% agar as a basis, the author has studied the influence of maltose and asparagin in the presence of constant quantities of the salts, and has determined for each substance, in the presence of a determined quantity of the other, the limits of concentration within which zygospores are formed. With maltose or asparagin alone zygospores are not formed. The influence of the salts was studied in the presence of determined quantities of maltose and asparagin. Potassium phosphate is indispensable to zygospore formation while $MgSO_4$ is not. KNO_3 and ammonium tartrate served equally well as sources of N. Of the 15 amino-acids studied asparagin was most favorable to zygospore formation. Acidity also plays an important rôle, a pH of 7.5-8 giving the largest number of zygospores. Small quantities of $CuSO_4$ accelerated zygospore formation. Differences in the plus and minus strains were found in their appearance on certain natural media, in the curves of growth and absorption, in their reactions to certain toxic substances, in serological reactions, and in the accumulation of carotin (in the plus progamete). A strain of bacteria was found which would attack the plus strain but not the minus strain. The author concludes that these various biochemical characters must be regarded as secondary sexual characters representing the metabolism of each sex. The expression of this metabolism must lie in the chemical composition of the medium, in the nutrition offered, and in the physio-chemical conditions in which the organism finds itself. To one medium the 2 sexes may very well behave in an absolutely identical manner while to another the sexual dimorphism may be very sharp.—*L. Dosdall.*

15588. **SIGEMATU, YOSINORI. Hardening of bamboo shoots with special reference to the growth of the shoots.** *Bull. Miyazaki Coll. Agric. & Forestry* 3. 121-128. 5 fig. 1931.—In 3 *Phyllostachys* and an *Arundinaria*, using Miura's durometer, hardness at first increased very slowly; a certain time later it suddenly advanced, after which it progressed regularly. Rate of growth is greatest while the hardness increases the first few degrees; afterwards it decreases as the hardening increases. Hardness increases in *A. simoni* much more slowly than in *Phyllostachys.*

15589. **SWINGLE, WALTER T. Metaxenia in the date palm. Possibly a hormone action by the embryo or endosperm.** *Jour. Heredity* 19(6): 257-267. 1928.—Metaxenia, the direct effect of pollen on tissues of the ♀ parent, is tentatively explained as the result of the action of hormones secreted by the embryo or endosperm or both, which diffuse out into the tissues of the ♀ parent and exert a characteristic effect, depending upon the ♂ parent from which the pollen came. Evidence is adduced to show that the embryo and endosperm of the date show remarkable chemical activities during their development and interact to some extent on each other and probably on the nearby tissues of the seed and ovary walls.—*L. M. Dickerson.*

15590. **VINCENT, GUSTAV. Věk jehličnatých dřevin a jakost jejich šišek. [Age of conifers and the quality of their cones.]** *Věstník Českoslov. Akad. Zem.* 7(1): 44-48. 1931.—The length of cones was influenced by the age of the tree. Correlations were not rectilinear, but their regression could be expressed by a curve equation. The maximum cone length was obtained in 40-100 yr. spruce and 60-100 yr. fir. The yields from the cones, water contents and fuel values of dry substance were not influenced by the ages of mother trees. Differences were more quantitative than qualitative.—*G. Vincent (transl. by H. I. Baldwin).*

15591. **VINCENT, GUSTAV. Věk jehličnatých dřevin a jakost jejich semen. [Age of conifers and the quality of their seed.]** [In Czech and German.] *Věstník Českoslov. Akad. Zem.* 7(1): 48-53. 1931.—The fresh and dry wts. of seed and their caloric value were influenced by the age of the mother tree. The correlations were not rectilinear, but their regression could be expressed by a curve equation. The maximum dry wt. and caloric value were found in 60-100 yr. spruce and fir. The germinative capacity of the seed was not influenced by the age of the mother trees, nor were any differences found in the anatomical structure of seed from trees of different ages. Observed differences in seed quality were not noticeable in the height-growth of the resulting seedlings. The differences were more quantitative than qualitative. Differences in wt. and total food reserves were established, but not in water content or relative representation of separate foods. Individual differences occurred in seed of 60-100 yr. spruce and fir, and closer approximation of the sought optimum age was impossible.—*G. Vincent (transl. by H. I. Baldwin).*

15592. **WEISKOPF, BOHDAN. O korelačních podmínkách vzrůstu pupenů u klíčnich rostlin Papilionaceí. [Correlative conditions of growth in length of buds in some Papilionaceae in germination.]** [French summary.] *Biol. Spisy Vysoke Školy Zvěrolékařské Brno (Publ. Biol. École Vét. Brno)* 6: (67-103). 1927.—Lateral buds of young seedlings of *Pisum sativum*, which had been de-

capitated above several basal nodes (especially above that of the 1st compound leaf), exhibited some regular elongation relationships dependent upon the progress of their embryonic development, upon the influence of reserve materials varied experimentally, and upon certain external factors, notably light. The arrest in the development of the cotyledonary buds of *P. sativum, Phaseolus multiflorus,* and *P. vulgaris* comes not only from the correlative effect of the terminal bud (the youngest parts lack any influence) but also from that of the region of growth deprived of buds and even from those parts where development has already been completely arrested (internodes and leaves). Certain substances, such as diastase, produce the same effect. The inhibitory substances are able to pass through a thin layer of gelatine which does not allow the passage of reserve materials or minerals in an amount sufficient for the normal growth of the stem.—*Author's résumé (transl. by A. S. Foster).*

GERMINATION, DORMANCY, RENEWAL OF ACTIVITY

15593. COMINI, ADELE. La germinazione dei semi delle orchidee. [Germination of orchid seed.] *Natura [Milano]* 18(4): 131-136. 1927.—Experiments show that old cultures of *Rhizoctonia* (isolated for more than a yr.) do not immunise but kill the seedlings; i.e., they are more virulent than young cultures. The cultures exposed to 40° C. die but those exposed to 30° C. are not attenuated; in fact when placed in contact with seedlings they invade the roots and behave the same as those not heated. Sugars in the culture medium do not keep the plants from entering into a symbiotic relationship when the opportunity offers. Hence one cannot speak of immunising phenomena in these experiments.—*Author's summary (transl.).*

15594. CRESCINI, FRANCESCO. Osservazioni e richerche su una crucifera infestante. [A cruciferous weed.] *L'Italia Agricola* 3: 4-7. 1930.—In *Calepina corvini,* which is found everywhere in the fields around Bologna, seed scattered over the surface of the soil or lightly covered by it, show, under the influence of solar heat, a higher relative germination and also a more rapid one than seed not so treated. The effect of drying is greater the longer it is continued. The germination of the seed is adapted to a position in free, humid air which does not have a greater daily oscillation of temp. than 30-31° for the maximum and 20-21° C. for the minimum. A theory is developed to explain the periodical appearance of this plant around Bologna.—*F. Crescini (transl. by B. F. Lutman).*

15595. DAVIS, W. E. Primary dormancy, after-ripening, and the development of secondary dormancy in embryos of Ambrosia trifida. *Amer. Jour. Bot.* 17 (1): 58-76. 4 fig. 1930.—The embryos of fruit of *A. trifida* are dormant at maturity. They after-ripen slowly in dry storage, but much more rapidly and completely in a saturated condition at 0°-10° C. The time required for the after-ripening of freshly harvested fruit at the optimum low temp. (5° C.) is about 3 mo. While the fruit are at low temp. there is a slight rise in the acidity together with a pronounced rise in the catalase content of the imbibed embryos over those of air-stored fruits. If the embryos after-ripened in either dry storage or at low temp. fail to germinate when placed at high temp., due to enveloping membranes that interfere with the gaseous exchange between the embryos and the external atmosphere, they revert to the dormant condition and must again be after-ripened before germination will take place. The time required for development of secondary dormancy in after-ripened embryos is 30-60 days. The same embryos may be repeatedly made dormant and after-ripened by alternating periods at high temp. and sub-minimal O supply with periods at low temp. and adequate O supply in water imbibed condition. The cause of secondary dormancy appears to be restricted respiration at high temp., which in turn is caused by the low permeability to O of the membranes which envelop the embryo, mainly the nucellar membrane, which consists of a single layer of living cells immediately next the embryo. While the development of dormancy is associated with restricted or incomplete respiration, the presence of a supply of O seems necessary. Embryos of fruit embedded in agar in order to reduce further the O supply to the embryos developed dormancy more slowly than embryos of fruit at the same temp. but free from agar. When the embryos become dormant, both the respiration and the catalase activity are reduced. At the germination temp. employed, the catalase activities of fruit, seed, and naked embryos bear about the same relation to one another as the respiratory capacity.—*Author's summary.*

15596. DUFRÉNOY, JEAN. Sur des phénomènes préparant la germination. *Compt. Rend. Soc. Biol.* 18(17): 1497-1498. 2 fig. 1928.—Beans, deprived of their teguments, germinated in 2 days at 21° or 27°; those with them required 8 days. At 15° both denuded and undenuded beans took 8 days to germinate. Denuded peach seed began to germinate in 2 days, but growth ceased until transferred to 15°. Prior refrigeration at 3° for 3 days led to a leafy stem in 10 days.

15597. ESDORN, J. Untersuchungen über anomale Kleekeimungen. *Landw. Versuchs-Stationen* 112(1/2): 103-113. 1931.—In germination tests of hard coated, scratched legumes, the experimental method employed influences the % of abnormal sprouts produced; greater moistness of the seed bed increases the number while higher germination temp. reduces it. In any case the differences vary with the different kinds of seed. Of the seed tested they are greatest for crimson clover (*Trifolium incarnatum* L.), but considerable also for black medic (*Medicago lupulina* L.), kidney vetch (*Anthyllis vulneraria* L.), and red clover (*T. pratense* L.). Even here the greatest differences appear only at the higher temp. (26° C.). Alfalfa shows appreciable differences only at the higher temp. The water content of the seed when brought into the germination bed is important; relatively dry seed react to different degrees of moistness more strongly than relatively moist seed.—*Author's summary (transl. by G. T. Harrington).*

15598. EVANS, M. M., and GEORGE HARRAR. Germination of the oospores of Sclerospora graminicola (Sacc.) Schroet. *Phytopath.* 20(12): 993-997. 2 fig. 1930.—Spores of *S. graminicola* shaken into a beaker of sterile water (the surface of the spore-furnishing material may be sterilized, when necessary, with 5% lactic acid and washed in sterile distilled water) germinated 5-30% in 24 hrs. at room temp. Germination was not affected by pH changes at pH 4.5-7, and the medium seemed to have little influence.—*W. A. Whitney.*

15599. GRÜSS, J. Bau und Semipermeabilität der Gerstenfrucht- und Samenschale. *Wochenschr. Brauerei.* 46(7): 61-66; (8): 74-80. 20 fig. 1929.—The results of A. Brown's investigations were in general confirmed. Divergences appeared however in that the soaking of the grains in dilute H_2SO_4 allows the acid to penetrate the pericarp. By means of preliminary experiments and a method of imbedding in wax, it was shown histologically that the testa, impermeable to the acid, possesses a break at the base and at the tip of the barley grain. NH_3 and SO_2 penetrate the pericarp unhindered and HCl is only slightly retarded. These breaks have been termed "the upper and the lower diffusion-passages." Otherwise the testa is semipermeable or impermeable for most substances capable of diffusion. However, in older grains these substances could penetrate through cracks into the endosperm. In the same way, material contained in the grain, mainly oxidase, peroxidase in combination with diastase, and antioxytasins, diffused into the water used in soaking the grains.—*J. Grüss (transl. by A. S. Foster).*

15600. LOOMIS, W. E., and M. M. EVANS. Experiments in breaking the rest period of corms and bulbs. *Proc. Amer. Soc. Hort. Sci. 25*: 73-79. 1928.—The foundation of a method for forcing gladiolus corms which combines high storage and high soil temp. is outlined.

Corms have given responses in all the treatments used analogous to the responses of Irish potato tubers.—Fully matured but still green onion bulbs are greatly shortened in rest period by dry storage at 95-105° F. for 2-3 weeks. Bulbs cured in the field will probably give best results at the lower temp. The method of transverse cutting, recommended by Boswell, is surpassed by longitudinal splitting of the tops of the bulbs, so as to admit air without removing any of the food reserve. During the early part of the rest period, onion and probably other similar bulbs can be forced at once by splitting combined with forced injection of tap water. The method is especially useful in identification of varieties or in inspection for bulb-borne diseases. It is suggested that the rest periods of vegetative organs containing stored starch are shortened by ethylene, ethylene chlorhydrin, ether, and similar compounds, while organs such as bulbs, containing little or no starch, will not show the same response. This theory has held in the work done with tulip, narcissus, and onion bulbs; gladiolus and crocus corms; Irish potato tubers; and apple twigs.—*From authors' summary.*

15602. **SMITH, ORA.** Relation of some physical and chemical changes to potato dormancy. *Proc. Amer. Soc. Hort. Sci.* 25: 86-90. 1928.

15603. **STAHL, CHR.** Die Dauer der Keimversuche. Dürfen die Keimversuche früher abgeschlossen werden, als es bis jetzt im Allgemeinen der Fall ist? *Compt. Rend. Assoc. Internat. Essais Semences* 11-12. 117-128. 1930.—Results of tests show that, with the exception of grass seed tested shortly after harvesting, a very inconsiderable number of seedlings is produced during the last days of the periods laid down in the rules governing germination tests, and that these periods may consequently be reduced for a number of sp. without any marked influence on germination results. This applies to *Lolium perenne,* 14 days; *L. italicum,* 14 days; *Festuca pratensis,* 14 days; *Bromus arvensis,* 10 days; *Dactylis glomerata,* 18 days; *Poa trivialis,* 18 days; *Daucus carota,* 14 days; *Beta vulgaris,* 12 days; *B. vulgaris saccharifera,* 14 days; *Brassica campestris* var. *rapifera,* 8 days; *B. napus* var. *napobrassica,* 10 days. According to the examinations in question, it is not advisable to reduce the periods fixed for the germination tests of legumes and for a number of garden vegetables.—*W. Crocker.*

15604. **ZENARI, S.** Il carattere "semi duri" in rapporto con la discendenza e l'ambiente. [The character "hard seed" in relation to heredity and environment.] *Ann. di Bot.* 18(2): 174-215. 1929.—Seed of various Leguminosae, Malvaceae, and Cistaceae were tested both genetically and biologically. A 3-yr. selection did not much influence the % of hard seed. This character is irregular and can not be considered hereditary; it is strictly related to the degree of maturation of the seed. The impermeability of seed is influenced by climate and soil; shade and rainfall diminish the % of hard seed. There also exist external factors which produce a kind of supermaturation which alters the tegument of the seed and lowers the % of hard seed. These factors are essentially the product of the bacteria and molds of the soil.—*A. Biraghi.*

TROPISMS, GROWTH AND TURGOR MOVEMENTS

15605. **BOSE, JAGADIS CHUNDER** (transl. into French by **EDOUARD MONOD-HERZEN**). Le mécanisme nerveux des plantes. [Nerve mechanism in plants.] 228p. 80 fig. Gauthiers-Villars et Cie.: Paris, 1931. Pr. 45 fr.

15606. **CASTLE, E. S.** Phototropism and the light-sensitive system of Phycomyces. *Jour. Gen. Physiol.* 13(4): 421-435. 1930.—Reaction times of both the "light-growth" response and the phototropic (bending) response of dark-adapted sporangiophores of *P. blakesleanus* progressively increase in a similar manner as the duration of exposure to light decreases. Both modes of response are thus considered to be founded on the same basic light-sensitive system. Analysis of the compound reaction time shows that the rate of the process occurring during the latent period is directly proportional to the amount of preceding photochemical action.—*E. S. Castle.*

15607. **COELINGH, WILLEMINA MARIA.** Over stoffen, die invloed uitoefenen op de aggregatie by Drosera. [Substances influencing aggregation in Drosera.] [Thesis: Univ. of Utrecht.] 76p. 8 fig. N. V. Hollandia-Drukkerij: Baarn, 1929.—A study was made of the influence of the terminal gland on the distribution of the process of aggregation in the pedicel. If a tentacle from which the terminal gland has been removed is cut from the leaf and placed in a solution of pepsin or meat extract, the distribution of the aggregation appears to be the same as in uninjured tentacles; it is always strongest in the part of the pedicel nearest the gland. It was assumed that each gland regularly produces a substance which travels down the pedicels, not inducing aggregation itself, but bringing the cells into a state in which the aggregation is possible. Separated tentacles without terminal glands lose their power of aggregation in a solution of pepsin after having been immersed in water or a sugar solution for some days; the power of aggregation is maintained longest in the central part of the tentacle. Nevertheless, one can make refractory tentacles aggregate again with an extract of the glands. This extract can be boiled or evaporated without losing its power, but it cannot be kept longer than a few days; the active substance seems destroyed, probably by the action of microorganisms. The dried extract can be kept indefinitely. Aggregation seems possible also outside of the tentacle cells; thus it was observed in the cells of the leaf, calyx, bracts, and also in the hairs and papillae which cover the green parts of the plant. The 2 kinds of papillae also seem to have to a less degree the power of producing the "aggregating substance." Extracts of glands are not the only substances inducing aggregation in tentacle pieces not responding to pepsin or meat extract. Saliva can be boiled a long time and filtered without losing its aggregating property. The part of dried saliva which is soluble in 96% alcohol causes aggregation as well as the rest. The active substance in saliva is neither a ferment, nor albumen, nor KCNS. Of the salts found in saliva, the phosphates alone induce aggregation. Strong aggregation was caused also by asparagin, aspartic acid, and alanin; less by leucin and glycin; practically no results were obtained with tyrosin, kreatin, and urea. Taka diastase and Rhenania trypsine showed a weak influence. No results were obtained with some compounds which reduce the surface tension (saponin, amyl alcohol) and some which increase the swelling of colloids (KCNS). The possibility that these substances act only because of their pH is rejected.—*M. J. Sirks.*

15608. **FIGDOR, W.** Über den positiven Geotropismus der Achsenknollen von Gloriosa superba Linn. und G. rothschildiana O'Brien. *Ber. Deutsch. Bot. Ges.* 47(9): 548-553. 2 fig. 1929.—These two members of the Liliaceae develop curious tubers, the tips of which continue the growth of the plants in the succeeding season, the rest of the tuber being a food storage organ. These tubers grow into the soil, becoming the shape of an inverted U or of a compressed horse-shoe with the concavity facing downwards. That this position is the result of gravity is shown by 2 sets of experiments. Normal tubers laid horizontal in pots and covered by a thin layer of soil produce normal plants, but in the course of the season these plants form the usual tubers for the next season and these turn down as if they had been formed by plants starting in the usual position. Another set of plants in which glass plates and Pfeffer's solution take the place of soil react entirely normally whatever the position of the tubers, except that they did not come into bloom, although in the solution and on the glass, light had free access. It is concluded that gravity

principally determines the direction of development of the horse-shoe shaped tubers.—*G. J. Peirce.*

15609. **HALKET, A. C. The flowers of Silene saxifraga, L.; an inquiry into the cause of their day closure and the mechanism concerned in effecting their periodic movements.** *Ann. Botany* 45(177): 15-37. 9 fig. 1931.—These flowers open at night and close during the day. The flowers investigated were of 2 kinds, hermaphrodite and "♀" flowers; the latter have vestigial stamens, are smaller, and can be easily distinguished in the bud. Both kinds of flowers were borne on some plants, but only "♀" flowers on others. The petals of a bud unfold towards evening, the blades bending back until they are approximately at right angles to the claws. The flower remains open until morning, when the petals gradually roll up and the flowers close until evening. On wet days the flowers remain open. Flowers open and close several times; a "♀" flower opened 5 times (average). A change in light intensity or an alteration of temp. in a saturated atmosphere has no effect; a saturated atmosphere hastens the unfolding of closed petals; young, closed flowers always open if they are supplied with water. The movements are caused by the alteration of the water-content of the cells and are therefore "turgor movements." Open petals close when water is taken from their cells, and closed petals open when water is added to them. The time a "closed" petal takes to open is increased if the rate of entry of water into its cells is decreased. The curvature of a longitudinal section of a petal increased with the decrease in the amount of water in its cells. The degree of opening of a "closed" petal in a given time varies with the rate of entry of water into its cells. The salient features of the anatomy of the blade of the petal are that (a) the vascular bundles lie very near to the lower surface, (b) the mesophyll cells are long and narrow, and are orientated with their long axes in the plane of the long axis of the petal; and (c) the epidermal cells of the lower surface have thicker walls than those of the upper surface and contain chloroplasts. The change in volume of the cells of the mesophyll and the upper epidermis, in passing from the fully-turgid to the non-turgid state, is considerable, while the change in volume of the lower epidermal cells is comparatively small. The cells of the lower epidermis have a higher osmotic pressure than those of the upper. The movements depend mainly on the difference in the "elasticity" of the upper and lower surfaces of the petal and are probably affected by the age of the flower. The rate of movement, apparently, decreases as the flower ages and the movements cease after some days. The "closed" petals do not surround, and so protect, the stamens and carpels, but the rolling-up of the petals may be useful biologically; the loss of water from the surface of the flower is reduced by its closure and more water, therefore, remains in its tissues and is available for the stamens and carpels, which otherwise might suffer from a deficiency of water.—*Author's summary.*

15610. **KISSER, J., und R. STASSER. Untersuchungen über die bei der Keimung geschälter Leguminosensamen auftretenden Wurzel- und Hypokotylkrümmungen.** *Beitr. Biol. Pflanzen* 18(2): 161-184. 2 pl., 2 fig. 1930.—Seed of the several legumes studied (*Pisum, Phaseolus, Vicia, Lupinus, Soja, Lens*) show a bending of the root and hypocotyl with growth when the embryos are removed from dry seed, and the bend is always convex on the face next to the cotyledons. In some cases the root and hypocotyl form a closed spiral of 3 or 4 coils. If the seed are soaked several hrs. before removal of the coats, no bending occurs. If dry intact seed are exposed to the vapor of 1% Br water for 25 or more min., or formaldehyde vapor, similar bending occurs. The effect of these vapors is prevented by vaselining the coat over the hypocotyl before treating. In commercial seed there is generally a small % of bending due to pressure injury on outer flank of hypocotyl in harvesting, threshing, and handling. This does not occur in self-harvested seed. In more extreme injury, the root dies. With slight injury the root straightens and grows normally. The bending is due to the killing of several layers of cells on the outer flank of the hypocotyl. This is easily seen microscopically after treatment with poisons. When dry, the seed-coats adhere tightly to the outer flank of the hypocotyl and their removal causes an over-extension of the superficial cells, resulting in death later. While the response is mainly due to mechanical effects, positive and negative traumatotropism may cause some curving. Similar effects of seed sterilizers have been reported by others.—*W. Crocker.*

TEMPERATURE RELATIONS

15611. **BUSSE, W. F., and C. R. BURNHAM. Some effects of low temperatures on seeds.** *Bot. Gaz.* 90(4): 399-411. 3 fig. 1930.—Seedlings grown from flax seed that had been frozen in liquid air sometimes showed a high % of abnormal plants having fasciated or doubled stems and hypocotyls, but seedlings from untreated seed practically never showed these abnormalities. 10 different varieties, each a pure strain, and 1 lot of common seed which were tested gave widely different % of abnormal plants (0-70%). The time of cooling the seed, or the time between freezing and planting, had little effect on the number of abnormal seedlings. When the moisture content of the seed was increased about 10% before freezing, germination was not affected, but the number of abnormal plants was reduced to almost zero. Freezing in CO_2 snow had about the same effect as freezing in liquid air. Some possible causes for this twinning of the growing point are discussed. Cotton seedlings also grow abnormally if the seed are first cooled in liquid air. Here the cotyledonary leaves become cracked and broken, due probably to purely mechanical causes, but the secondary leaves grow normally.—*W. F. Busse.*

15612. **CAROLUS, R. L. Effect of seasonal temperatures on chemical composition of kale (Brassica oleracea var. acephala).** *Proc. Amer. Soc. Hort. Sci.* 27: 502-508. 3 fig. 1930(1931).—Kale plants showed an increase in dry matter, total, reducing, and invert sugars, and hydrolyzable substances after a decline in the average mean temp. A 3-day period was necessary to start the accumulation or reduction in the % of these substances. The hardening process resulting from low temp. was associated with an increase in sugar content and, therefore, an increase in edible quality.—*R. L. Carolus.*

15613. **CRESCINI, F., ed A. TETTAMANZI (with introduction by F. TODARO). Sulla resistenza del grano alle basse temperature. [Cold resistance of wheat.]** *Italia Agric.* 66(7): 546-552. 1929.—During the exceptionally cold winter of 1928-29, observations were made on the resistance of the various parts of the wheat shoots to cold. Under presumably uniform conditions of temp., 4 pure line strains of wheat all showed that in a given plant the leaf sheath, younger leaves, and younger tillers were more cold-resistant than the leaf blade, older leaves, and older tillers respectively. Moisture, ash, total N, K and P were not distributed so as to be related to the cold resistance, but reducing sugars were highest in the hardiest organs.—*F. Crescini (transl. by H. S. Wolfe).*

15614. **FIGUROVSKY, J. V. (transl. by H. KORDES). Analyse der gesamten Lufttemperatur (Wärmesumme), die von den Pflanzen innerhalb einer Vegetationsperiode benötigt wird. [Analysis of total air temperature required by plants during a vegetative period.]** *Pflanzenbau, Pflanzenschutz u. Pflanzenzucht* 7(2): 36-43. 4 fig. 1930.—Theoretical discussion.

15615. **STERN, K., und E. BÜNNING. Über die tagesperiodischen Bewegungen der Primärblätter von Phaseolus multiflorus. I. Der Einfluss der Temperatur auf die Bewegungen.** *Ber. Deutsch. Bot. Ges.* 47(9): 565-584. 13 fig. 1929.—Bean plants grown in the dark exhibit a reversal of daily leaf movements when the night temp. is a few degrees higher than that of the day. When the temp. changes are produced at intervals of 16 hrs. instead of 24, the leaf movements follow approxi-

mately the 16-hr. rhythm. Small temp. fluctuations of 1° or less, occurring in 1-2 hrs., often have synchronous leaf movements. These, however, differ from the daily periodic movements influenced by 16- or 24-hr. temp. fluctuations, the reaction time of the latter being much longer. The effects of light and temp. changes upon the leaf movements are similar.—*W. J. Himmel.*

RADIANT ENERGY RELATIONS, PHOTOPERIODISM

15616. BURGER, GEORGE N. Critical wave-lengths in killing bacteria. *Bull. Basic Sci. Res.* [*Univ. Cincinnati*] 2(1): 46-54. 5 pl. 1928.—Filters of various concentrations of lead acetate in acetic acid were used to absorb and remove ultra-violet radiations of certain shorter wave-lengths, allowing the longer radiations to penetrate. Killing wave-lengths were determined for *Staphylococcus aureus, S. albus, S. citreus, B. paratyphosus* B, *B. dysenteriae* (Shiga), *Micrococcus catarrhalis,* and *B. coli communis.* A more accurate determination was made by projecting the spectrum of a quartz Hg arc on agar-coated slides inoculated with the above organisms and *B. subtilis.* The longest killing wave-length (3020 Å) is the same for all bacteria tested, suggesting that the quantum theory is applicable to the bactericidal action of u.-v. light. The maximum killing wave-lengths lie at 2800, 2650-2700, and 2540 Å.—*J. L. Cameron.*

15617. COLLA, S. Azione della lucé di Wood sulla posizione dei cloroplasti nella cellule. [Action of ultra-violet light on the position of chloroplasts in the cells.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 318-320. 1930.—Following irradiations in the range 3300-3900 Å, migration of the chloroplasts was observed, these moving essentially toward the nucleus. It is a question whether or not these movements are to be attributed to phototropism alone. —*M. Comel.*

15618. DETWILER, S. B. The effect of ultra-violet light on germination of seeds and growth of seedlings of Ribes rotundifolium Michx. *Jour. Forest.* 29(1): 131-133. 1931.—Exposure of seed for 5, 10, and 20 min. to light of 2700-3200 Å at 3 ft., produced no greater % of germination than was obtained from untreated seed, but did cause a stunting of early growth, with a hint of resistance to disease.—*P. C. Wakeley.*

15619. GOODSPEED, T. H. The effects of X-rays and radium on species of the genus Nicotiana. *Jour. Heredity* 20(6): 243-259. 17 fig. 1929.—F_1, F_2, and F_3 progenies following treatment with x-rays or gamma rays have been grown. When dry, soaked, or germinating seed; growing points of seedlings; or mature or immature sex cells are given appropriate treatment, alterations in the hereditary material appear in later generations. Certain of these alterations are quantitative and are followed by changes in the amount and distribution of nuclear material in the cell divisions which produce vegetative or reproductive tissues; others are qualitative and produce distinctions in the genetic factors which are inherited. Very heavy dosage with x- or gamma rays of dry or soaked seed has only a retarding and no immediate lethal influence on germination and early seedling growth. Relatively light dosage proves immediately or ultimately lethal to all seed which are germinating or are in the youngest seedling stages when treated. Older seedlings when irradiated often exhibit great deformation and are incapable of further growth until side shoots below the irradiated region develop.—*From author's abstract.*

15620. GUERRINI, GUIDO. Influenze delle luci monocromatiche sull'azione del Saccharomyces cerevisiae in presenza di glucosio. [Action of monochromatic light on activity of S. cerevisiae, when glucose is present.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 635-636. 1930.—The amount of CO_2 produced was greater when the cultures were exposed to light. The amount was maximum when the light was filtered through a red screen, less with yellow and green screens, and very slight with a blue screen.—*M. Comel.*

15621. JÜNGLING, O., und H. LANGENDORFF. Über die Wirkung verschieden hoher Röntgendosen auf den Kernteilungsablauf bei Vicia faba equina. *Strahlentherapie* 38(1): 1-10. 1930.—X-rays disturb the course of cell division in roots of *V. f. equina.* Small doses which do not produce any injury visible microscopically, accelerate mitosis. Larger, injurious doses produce an undulant course of cell division, which is not in accord with the rhythm of mitosis in unirradiated roots. Still higher doses lengthen the time between mitoses, slowing down the course of effects connected therewith.—*Authors' summary (transl. by P. M. Suski).*

15622. KNOTT, J. E. Further localization of the response in plant tissue to relative length of day and night. *Proc. Amer. Soc. Hort. Sci.* 23: 67-70. 1926.—The catalase activity of the apical bud of *Cosmos* decreases as the change from vegetative to reproductive growth is caused by subjecting the tip alone to a 10 hr. day. The change is not paralleled in an adjacent leaf which was also covered. The formation of a flower bud at the apex stimulated greater vegetative growth of the shoots at the nodes below. Increased catalase activity was evident at the 1st node below the tip.—*Author's summary.*

15623. KÜSTER, A. Die Wirkung der Röntgenstrahlen auf die nyktinastischen und seismonastischen Bewegungen. *Fortschr. Geb. Röntgenstrahlen* 40(2): 242-248. 1 fig. 1929.—X-rays produce a permanent paralysis of the pulvini of the leaves of *Mimosa* and *Phaseolus,* proportional to the dosage. The hard rays are more effective in this than the soft. The paralysis does not interfere with the movement of the water stream through the pulvini.—*H. J. Fuller.*

15624. McKINNEY, H. H., and W. J. SANDO. The behavior of winter wheat in artificial environments. *Science* 71(1852): 668-670. 1930.—Glass causes abnormally long foliage and reduces sideshoots in winter wheat grown in full daylight. The same effects are produced by tungsten lamps and to a less extent by Cooper-Hewitt lamps. 7-8 hrs. daylight daily through window glass at 59°F. produced nearly normal plants during their early vegetative stage. 2-3 experimental crops of winter wheat can be obtained in 12 mo. by holding small seedlings near 32°F. in the dark for 65 days or by growing plants in an 8-hr. day at 50°F. for 36 days, then 60 F. for 18 days, following either initial treatment with long days at 70-95°F.—*H. H. McKinney.*

15625. NORRIS, ROBERT J. An application of filtered ultra-violet radiation to sterilization of diastatic enzyme solutions. *Bull. Basic Sci. Res.* [*Univ. Cincinnati*] 2(1): 93-104. 4 fig. 1928.—A ½% solution of a diastatic enzyme (of anticipated value to the baking industry) was treated with u.-v. rays of various wave-lengths, by use of special filters; the enzyme sensitivity was determined by the method of Shaffer and Hartman. 2760 Å was the most favorable bactericidal wave-length, giving complete sterilization with a minimum of enzyme destruction. The lengths of time required for sterilization of solutions of enzyme in increasing concentration (up to 10%) are reported.—*J. L. Cameron.*

15626. RAMSEY, G. B., and ALICE ALLEN BAILEY. Effects of ultra-violet radiation upon sporulation in Macrosporium and Fusarium. *Bot. Gaz.* 89(2): 113-136. 1 pl. 1930.—There is a definite stimulation of spore production in cultures of *Macrosporium tomato* and *Fusarium cepae* on exposure to u.-v. radiation produced by a quartz Hg arc. Increased spore production appears to be a result of stimulation rather than an indirect result of inhibitory action. Most spores were produced when filters were used whose lower limits of transmission were 2535-2800 Å. Slight stimulation results when filters transmitting no lower than 3120 Å are used, but those whose lower limits are 3334 Å or above are not effective. Radiations of 2535 Å and shorter stimulate spore production, but lethal effects also become noticeable. Greatest increase in spore production occurs when irradiated 15-30 min. on 3 successive days. Stimulation of spore production is not due to change in the culture medium as a result of irradiation, or to temp. fluctuation. Control cultures 2 weeks old, showing no spores, produced

hundreds of spores on irradiation. Long exposures to direct sunlight in May through filters transmitting no lower than 3120 Å induce abundant sporulation in both *Macrosporium* and *Fusarium*.—*G. B. Ramsey.*

15627. **SARTORY, A., R. SARTORY, et J. MEYER. Influence du radium sur la production des zygospores chez Mucor spinosus Van Tieghem (Zygonhynchus spinosus).** *Compt. Rend. Acad. Sci.* [*Paris*] 186(15): 1010-1012. 1928.—The organism used was isolated from the digestive tubes of different larvae of Coleoptera and Lepidoptera. The methods of Bainier and Blakeslee gave no evidence of sexual phenomenon in cultures. Irradiation in dosages of 5 millicuries per cm.² occasioned the sexual phenomena in a medium made up of gelatinized juice of carrot dissociated with NaCl. The same phenomena which had been encountered before in the study of the action of Ra upon the lower fungi were found: the latent period (5-8 hrs. after irradiation) specific for the medium, and the liquefaction of the medium. The organism seems to be much more sensitive to the action of Ra as the surface of the cellular mass exposed to the irradiation becomes greater, as shown by the dosages to which the Perisporiaceae and the Mucorineae are sensitive.—*W. K. Farr.*

15628. **STEVENS, F. L. The response to ultra-violet irradiation shown by various races of Glomerella cingulata.** *Amer. Jour. Bot.* 17(9): 870-881. 5 pl. 1930.—About 50 monosporous cultures of *G. cingulata* isolated from apples in various localities were irradiated. These cultures showed marked variations in color of mycelium, presence of setae, and production of acervuli and perithecia. Some races produced perithecia in dense stroma-like groups of 50-1000, others in smaller clusters, and a few produced scattered solitary perithecia. The perithecia varied from globose and beakless to flask-shaped and rostrate, while the ascospores were quite constant in shape and size. Some of the races gave rise to mutants, by sectoring, in plate cultures and one such mutant sector was found in an infected apple. Irradiation increased perithecia in races producing them normally and induced their formation in many races not producing them normally. Some failed to produce perithecia even when irradiated. The perithecia in irradiated cultures were always scattered or in very small groups. Formation of acervuli was strongly influenced by irradiation.—*B. B. Higgins.*

15629. **SZOLNOKI, I. Radioaktivität, Lichtelektrizität, und Kaliwirkung.** *Ernähr. Pflanze* 26(8): 177-180. 1 fig. 1930.—General discussion of work on plant pigments, photosynthesis, and respiration.

15630. **TEDIN, OLOF. Undersökningar över ljusets inverkan på groningen av tomatfrön. [Influence of violet light on the germination of tomato seed.]** [With English summary.] *Nordisk Jordbrugsforskning* [*København*] Heft 2/3. 108-126. 1931.—The effect of full light, darkness and violet light was studied. Whereas the tomato-seed germinates better in darkness than in light, it reacts against violet light like a typical light-demandant. According to Hollrung such seed are unfavorably affected by blue and violet light, whereas dark-demanding seed should respond favorably to these spectral regions.—*From author's summary.*

15631. **TEODORESCO, E. C. Observations sur la croissance des plantes aux lumières de diverses longueurs d'onde.** *Ann. Sci. Nat. Bot.* 11(2): 201-335. 1 pl., 91 fig. 1929.—Continuing earlier work, with the added precaution of employing the thermopile as a measure of the energy content of the colored light used, 43 experiments are described as illustrating results obtained in 170 tests with liverworts, vascular cryptogams, and phanerogams. To simplify the problem the visible spectrum was merely divided into the red-orange and blue-violet halves, each containing a portion of the green. For selective absorption of the light rays specially constructed double-walled bell glasses containing 7 cm. layers of 10% aqueous K-bichromate and 3.25-4.25% ammoniacal hydrated $CuSO_4$ solutions were chiefly employed. More concentrated solutions of chromic acid (which is very soluble) were substituted for the bichromate when it was desired to reduce the energy content of the red-orange rays to that of the blue-violet. For comparison, special blue and orange-red glasses were used as filters and combinations of ordinary colored glasses and films also were employed in constructing miniature glass houses for the plants. Ordinarily direct sunlight or diffuse light was used and tests were conducted at different seasons. In special cases an electric light placed at varying distances from the filters was used to secure equal illumination intensities. Screens of pure water or copper acetate were used to absorb infra-red radiation when measuring the intensity of the transmitted light, but these filters were not deemed necessary in conducting the experiments. To minimize the disturbing effects of photosynthesis, plant material well supplied with reserves was chosen and the tests were usually terminated before these reserves were exhausted. Spores of the lower plants were germinated in 2.0-.5% agar in Knop's solution of 1/10 normal concentration. Seed, tubers, or bulbs of some of the higher plants were germinated in sand, and in other cases older plants in pots were used. In certain cases only the terminal bud was placed under the light screens, the remainder of the plant being in open daylight. With some exceptions, the 2 halves of the visible spectrum differ in their effect on increase in length of plants. The longer wavelengths act like darkness, producing excessive elongation of internodes, petioles, and their cells and reducing the surface and the thickness of leaves. On the other hand, the effects of the shorter rays resemble those of white light. *Menispermum cocculus* and *Helianthus annuus* are partial exceptions to the rule. In some plants, red light increases the number of internodes. In sporelings of certain liverworts and ferns, the red-orange rays cause excessive cell elongation, the organism being reduced sometimes to a mere filament composed of a single series of cells. The red light also reduces cell division and in the early stages of growth only transverse dividing walls are seen, while the number of longitudinal walls ultimately formed is much reduced. These combined effects produce in these lower plants a characteristic etiolation like that seen in weak white light. In forms in which the spores are able to germinate in darkness (*Pteridium*) the etiolation produced by red-orange light is almost identical with that of total darkness. As soon as the reserve materials are exhausted, however, photosynthesis becomes a factor, and in the red light elongation outstrips that in darkness. In certain plants (*Conocephalum, Pellia*) the sporelings grown in red light are longer than those in the blue but shorter than those in white light, and as the intensity of white light is increased, instead of etiolation effects, the elongation is reduced. These plants act as if the reserves are exhausted and growth is dependent on photosynthesis. Hence the direct action of wavelength on growth (photomorphosis) can only be ascertained by using plants amply supplied with reserve materials and observing the action of the radiation on the transformation of these materials for growth purposes and during the growth. The blue-violet rays appear to be more favorable to normal development of the plant than the red-orange and it seems justifiable to assume that the natural form of plants developed in daylight is dependent primarily on the action of the former rays. The 2 ends of the visible spectrum likewise act differently on germination. Excepting the cases in which the spores are capable of germinating in the dark, the blue rays as compared with the red appreciably delay germination in the liverworts and vascular cryptogams.—*W. W. Garner.*

15632. **WESTON, W., A. R. DILLON, and E. T. HANLAN. The fungicidal action of ultra-violet radiation.** *Phytopath.* 20(12): 959-965. 2 fig. 1930.—*Mucor mucedo, Rhizopus nigricans, Sporodinia grandis, Cladosporium herbarum, Dematium pullulans, Pleospora herbarum, Neurospora sitophila, Fusarium sp., Sclerotinia trifoliorum,* and *Stereum purpureum* irradiated 9 min. a day for 2 weeks showed a progressively reduced growth rate

until a dormancy was acquired. Petri dishes equipped with covers of Sanalux or Vita glass were used. Coincident with the decreased growth rate, the mycelium progressed deeper into the potato-agar substratum. Following the termination of exposure, mycelial growth was renewed.—*W. A. Whitney.*

TOXIC ACTION

15633. **ALBERT, W. B., and W. R. PADEN. Calcium arsenate and unproductiveness in certain soils.** *Science* 73(1901): 622. 1931.—Observations and experimental data indicate that addition of large amounts of Ca-arsenate to gray, light, sandy-loam soils may interfere seriously with subsequent growing of As-sensitive crops, such as cowpeas, oats, cotton, and certain grasses.

15634. **BARKER, B. T. P. Investigations on the fungicidal action of sulphur.** *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 130-148. 1 pl. [1930].—Sixty-one sp. of higher plants were studied by sprinkling S on both sides of the leaves and clamping to them filter paper moistened with basic lead acetate; 15 colored the paper black or brown, 9 colored it faintly brown, and 37 did not cause any color change. Thus about ¼ gave evidence that H_2S had been formed, and this in Sept. when leaf activity was low. A larger % of lower forms, including several yeasts and common pressed yeast, showed this S reducing power. Also pulp of apple and Jerusalem artichoke show this power. Control plants without S gave no reaction with lead acetate paper. Strawberry leaves reduced KIO_3 that had been dusted on them, and $FeCl_3$ in a gelatine film placed against them; and water in which strawberry leaves had been immersed reduced $AgNO_3$. With some tissues a deeper stain of lead acetate paper was obtained if to the tissue and S a few drops of H_2SO_4 were added. Lead acetate paper was soon discolored when placed over the mouth of a flask containing a fermenting sugar solution with S in suspension. The boiled solution dropped on lead acetate paper produced a brownish-black stain, but the unboiled solution did not. The unheated liquid would not reduce $PbCO_3$ immediately, but would upon standing in a $PbCO_3$ suspension. From strawberry leaves dusted with S and kept under a beaker in sunlight, the first odor given off was aldehydic, the H_2SO_4 odor coming later; unsulphured leaves failed to respond similarly. Liquid paraffin drawn through a mass of sulphured strawberry leaves did not yield H_2S upon being heated, unless it was first acidified with a few drops of H_2SO_4. It is suggested that the first product of the reduction of S by a substance from the living plant is not H_2S but some substance that is stable at 100° C. in the presence of alkali, but in the presence of acid is easily broken down, yielding H_2S. Possibly glutathione is the reducing factor.—*W. H. Chandler.*

15635. **KRONE, PAUL R., and F. F. WEINARD. Experiments with solutions of chlorine and sodium chloride on pot plants.** *Proc. Amer. Soc. Hort. Sci.* 27: 444-448. 1930(1931).—Injury to pot plants due to Cl in solution in water starts at about 10 p.p.m. and increases with the concentration. Since very seldom more than 2 p.p.m. are used in purifying city water supplies, it is doubtful if injury often occurs from this source. As to salts in solution in water, damage occurs starting at a concentration of 200 p.p.m., characterized by a burning of foliage. Stunting of the plant occurs at 500 p.p.m. and injury increases with the concentration.—*P. R. Krone.*

15636. **LEJHANEC, G., I. A. PARFENTJEV, and B. SOKOLOFF. Influence of quinone on oxidation processes, proliferative activity and longevity of yeast.** *Proc. Soc. Exp. Biol. & Med.* 28(5): 540-541. 1931.—Quinone, a substance resulting from the decomposition of adrenalin, increased the O consumption of yeast cells when in concentration of 1: 500,000; depressed the reproduction of yeast when at the same conc., the effect being more pronounced at a conc. of 10^{-4}; and decreased the duration of life of yeast cells.

15637. **NICHOLS, SUSAN P. The effect of chloroform upon the rotation in the internodes of Nitella.** *Bull. Torrey Bot. Club* 57(3): 153-163. 1 pl. 1930.

15638. **STOKLASA, JULIUS. Biochemische Methoden auf dem Gebiete der Pflanzenhygiene.** [In: *Handbuch Biol. Arbeitsmeth.* Lief. 243. Abt. IX. **Chemische, physikalische und physikalischchemische Methoden zur Untersuchung des Bodens und der Pflanze.** Teil 3, Heft 6.] p. 865-986. 14 fig. Urban & Schwarzenberg: Berlin, 1927.—The following are among the subjects dealt with in considerable detail: Acute, chronic, and invisible effects, respectively, caused by SO_2, H_2SO_3, H_2SO_4; analyses of foliage of different plants affected by these impurities in air; critical comparison of methods of estimating these impurities; analysis of flue gases from various types of furnaces; detection and estimation of SO_2 and H_2SO_4 in foliage; effects of HF, SiF_4, and H_2SiF_6 on cells and the higher plants generally; and methods for detection and estimation of F in plant materials, minerals, rocks, clay, and soil. Less detailed treatment is accorded to the toxic effects of HCl and the estimation of Cl in plant material and soil.—*O. Owen.*

15640. **BUTCHER, R. ADAMS, and DENNIS E. HALEY. Introduction to agricultural biochemistry.** x+484p. 98 fig. John Wiley & Sons: New York; Chapman & Hall: London, 1932.

15641. **FOX, FRANCIS WILLIAM. The chemistry of the individual.** *Proc. S. African Chem. Inst.* 1931: 22-32. 1931.—A lecture, discussing the biochemical and biophysical interpretation of the differences between one man (or other animal) and another. Differences in chemical composition of blood and tissue; in reaction of urine, of gastric juice and of blood; differences in renal threshold of sugar secretion; "inborn errors of metabolism" (albinism, haemophilia, alcaptonuria, porphyrinuria, cystin excretion in urine, steatorrhea, and food or allergic idiosyncrasies). There is a brief review of endocrinology, with reference to accounting for personal differences on the basis of endocrine differences; diet is considered also.

15642. **GELLHORN, ERNST, (herausg. von). (Unter Mitwirkung von L. ASHER, W. von BUDDENBROCK, E. GELLHORN, C. OPPENHEIMER, und J. SPEK.) Lehrbuch der allgemeinen Physiologie.** 741p. 126 fig. Georg Thieme: Leipzig, 1931. Pr., 47 M.—As stated in the preface, this book is not limited to an introduction to general physiology. It consists of 7 synopses of recent developments by specialists in the field. I. Die Zelle als physico-chemisches System, E. Gellhorn. The author discusses permeability; electrolytes and their action; and H-ion concentration more fully than osmosis and surface phenomena. He includes a partial résumé of some of the recent views on bioelectric phenomena. II. Chemie der Zellvorgänge, C. Oppenheimer. This section considers the living substance as a chemical system; structural materials of the living substances; synthesis and decomposition of nutrients and cell substances, and the chemical mechanisms of cell processes. In the discussion of chemical mechanisms the author stresses enzyme action, and the theories of oxidation-reduction and O activation. III. Energetik der lebenden Substanz, C. Oppenheimer. The rôle of cell metabolism, work, and heat production are treated from a thermody-

namical point of view. IV. Die Zelle als morphologisches System [The cell as a morphological system], J. Spek. The main headings included in this section are: visible cell structure in the light of general physiology and the physiological reciprocal action between nucleus and cytoplasm. V. Allgemeine Physiologie der Entwicklung und Formbildung, J. Spek. Advances in the physiology of fertilization, cell division, embryological development and regeneration are presented. VI. Allgemeine Physiologie der Erregungsvorgänge, L. Asher. The section begins with a general discussion of stimulation, excitation, inhibition and "external" and "internal" conditions, and is followed by a résumé of the modern aspects of excitation and the quantitative relation between stimulation and excitation. VII. Tropismen, W. von Buddenbrock. A brief summary of present day views is presented. Each author includes a partial bibliography which consists chiefly of new books and the most important recent contributions. The more recent views of certain branches of general physiology are stressed throughout.—*H. F. Rosene.*

15643. ANSON, M. L., and A. E. MIRSKY. Protein coagulation and its reversal. The identity of normal hemoglobin with the hemoglobin prepared by the reversal of coagulation, as determined by solubility tests. *Jour. Gen. Physiol.* 14(5): 597-604. 1931.—Methemoglobin was denatured in solution by the addition of HCl. Reversal of denaturation was accomplished by partial neutralization with NaOH. After complete neutralization, and separation of some denatured protein, the rest of the protein was obtained as "reversed" methemoglobin which could be crystallized. Solubilities of 3 amorphous proteins, the original methemoglobin, the "reversed" methemoglobin, and a preparation obtained from hemin and "reversed" globin, were identical within 2%. This is evidence that a protein whose coagulation has been reversed is identical with the original native protein. —*D. I. Hitchcock.*

15644. ANSON, M. L., and A. E. MIRSKY. Protein coagulation and its reversal. Globin. *Jour. Gen. Physiol.* 14(5): 605-609. 1931.—The globin prepared from hemoglobin by the acid acetone method is denatured globin. The denaturation and coagulation of globin by acid acetone are reversible. Soluble globin can be obtained from the acid acetone globin even if the globin is first precipitated by trichloracetic acid or heated to 100°C. Hill and Holden's theory that they separated native globin from hemoglobin without any intermediate denaturation is not proven by their experiments.—*Authors' conclusions.*

15645. ANSON, M. L., and A. E. MIRSKY. Protein coagulation and its reversal. Serum albumin. *Jour. Gen. Physiol.* 14(6): 725-732. 1931.—It is possible to prepare crystalline, soluble, heat-coagulable serum albumin from coagulated serum albumin. In the cases so far studied, the more soluble a denatured protein, the more easily its denaturation can be reversed.—*Authors' conclusions.*

15646. ANSON, M. L., and A. E. MIRSKY. The reversibility of protein coagulation. *Jour. Phys. Chem.* 35(1): 185-193. 1931.—Hemoglobin, globin, and serum albumin, when denatured by the ordinary procedures, can by suitable technique be repeptized to soluble proteins which seem to be the same as the original native proteins. Perhaps denaturation of the coagulable proteins in living tissues and its reversal are biological reactions which are important in ordinary cellular processes.—*T. O. Stevens.*

15647. BANCROFT, WILDER D., and J. E. RUTZLER, Jr. The denaturation of albumin. I. Denaturation by heat. *Jour. Phys. Chem.* 35(1): 144-161. 1931.—Heat-coagulated egg-white sols are peptized by KI, KSCN, NH_4SCN, urea, $NaHCO_3$, formaldehyde, and cane sugar. NaOH is also effective, but a slight amount of hydrolysis occurs. Under ordinary conditions, ether does not denature albumin, and when it does, the denaturation is due merely to removal of adsorbed water from the colloid, not to any chemical change. Extraction with ether prevents, by some sort of colloidal mechanism, the coagulation of egg-white sols. Evidently the ether extracts something from the sol and so gives it heat stability, since the extracted material, which acts like crude lecithin from egg-yolk, can act as a coagulating agent. Immunological tests for species specificity have shown that coagulated and repeptized egg-white sols are identical with the original, as also have isoelectric point measurements. A mechanism of peptization has been proposed which initially involves mechanical disintegration of the protein coagulum by hot water, aided in some cases by ether, and is followed by further disintegration and peptization by the negative ions of various electrolytes.—*T. O. Stevens.*

15648. BISHOP, G. H., FRANK URBAN, and H. L. WHITE. A study of the blocking effect of membranes. *Jour. Phys. Chem.* 35(1): 137-143. 5 fig. 1931.—In connection with a study of the filtration process through the glomerular membrane of the kidney, an examination was made of the flow of solutions through cellophane membranes and through glass capillary "pore models" of 0.035-0.150 mm. inside diam., and varying in length and taper. When water or dilute KCl solution is forced through cellophane membranes under pressure of 80 mm. Hg. or less, filtration commences at a maximum rate when the pressure is applied and in 15-60 min. may fall off to as low as 10% of the initial rate. If the streaming potentials in certain pores of the membrane were less, either in magnitude or rate of development, than were those in others, a return circuit though these pores would develop. This would oppose electro-osmotically the flow of solution due to the pressure head, resulting in an apparent falling off in the rate of mechanical filtration, and would at the same time discharge the potential difference across the membrane. The streaming potentials measured with the glass capillaries varied for capillaries of different diam. and shape, and even for the same capillary from day to day. The reasons for these differences are at present not at all clear. But it is reasonable to assume that there are great variations in the sizes and shapes of the pores in membranes, and it seems probable that the consequent differences in streaming potential may be responsible for the "blocking effects" observed.—*T. O. Stevens.*

15649. BOGUCKI, M. Recherches sur la perméabilité des membranes et sur la pression osmotique des oeufs salmonides. *Protoplasma* 9(3): 345-369. 4 fig. 1930.—The egg membrane of trout eggs is fibrillar in structure and when placed in water becomes elastic, resisting the action of NaOH. It is permeable to crystalloids but impermeable to colloids. This does not vary with egg development. In water, it absorbs about 20% of its volume. The osmotic pressure of fertilized and unfertilized eggs placed in water diminishes 30-40% in com-

parison with those in the fish. This is independent of fertilization. The perivitellin forms parallel to the absorption of water and equals in size the quantity of water absorbed. Hypotonic electrolytes stop this formation. Formation takes place, however, in hypertonic non-electrolytes. Colloids eliminated by the ovular cell in the perivitelline space seem to be responsible for these effects due to imbibition.—*Author's summary (transl. by L. S. Moyer).*

15650. BRAVO, G. A., e F. BALDRACCO. Sulla combinazione del collagene coi coloranti. [Combination of collagen with dyes.] *Ann. Chim. Appl. [Roma]* 21(8): 355-365. 1931.—When proteins of animal skins are brought in contact with solutions of dyes there is under certain conditions a true chemical reaction in addition to the colloidal adsorption. Quantitative data from the study of this reaction permit calculation of the equivalent wt. of the skin protein (collagen) as around 740.—*Authors' summary (transl.).*

15651. BRIEFER, M. Photometric and electrometric measurements of gelatin behavior. *Industr. & Engineer. Chem.* 21(3): 266-270. 1929.—The physical characteristics of gelatin vary with the chemical treatment of the raw material and not with its biological history. The prevailing theory that gelatin is at its isoelectric point specifically at pH 4.7 was originally postulated on a half-truth and is no longer tenable. Experimental data prove that gelatin has no specific isoelectric point but that there exist 2 types of gelatin, one carrying positively charged and the other negatively charged ions, depending on the original chemical treatment of the raw material. Experiments show that the ionic state of animal skins, resulting from originally acid or alkaline treatment, is not changed with respect to the isoelectric point by subsequent treatment with electrolytes, and that the gelatins extracted from these materials have corresponding physical and chemical characteristics. The specific reactions of animal hide to chemical treatment, and the persistence of the initial effect, should be an important factor in the chemistry of leather. Additional details are given with respect to isoelectric turbidity.—*Courtesy Industr. & Engineer. Chem.*

15652. CAMPEN, P. van. An apparatus for the rapid measurement of the osmotic pressure of colloidal solutions. *Rec. Trav. Chim. Pays-Bas* 50(7/8): 915-920. 3 fig. 1931.—The apparatus depends on the measurement of an artificial pressure exerted on the liquid and the observation of the velocity of the solvent passing through the membrane at this pressure. The osmotic cell is so constructed that only 10 cc. of solution are necessary for a measurement. Measurements on the osmotic pressures of hydrophilic colloids required only ½ hr.

15653. DHAR, N. R. Influence of ageing on inorganic hydrophile colloids, cells and colloids in the animal body. *Jour. Phys. Chem.* 34(3): 549-553. 1930.—A further elaboration of the theory that ageing of organisms and the "ageing" of hydrophilic colloidal systems are substantially identical phenomena.

15654. EWLES, J., and J. B. Speakman. Examination of the fine structure of wool by X-ray analysis. *Proc. Roy. Soc. [London] B* 105(740): 600-607. 1 pl., 1 fig. 1930.—X-ray fiber diagrams of 3 typical wools were obtained using the monochromatic pinhole method and iron radiation. Cotswold wool, unstretched and under ordinary atmospheric conditions of moisture, gave a definite fiber pattern, while the same wool stretched 30% in dry air gave a different diagram. A tentative interpretation is given in terms of fine structure which is in conformity with the theory of fiber structure deduced from stress-strain relationships. X-ray fiber diagrams were also obtained from Geelong 80 Merino and from Australian Merino 64 quality. The pattern of Geelong Merino, while still showing fiber structure, was less definite than the Cotswold, suggesting an ellipsoidal cell, while the 64 Merino showed only the least trace of ordered arrangement. Probably these 3 types are significant of the development of crystalline structure in wool and of its cause, the wool beginning its existence as a spherical cell of gelatinous material which elongates during growth, setting up strains which give rise to ordered and preferential arrangement along the fiber axis.—*J. Ewles.*

15655. GROLLMAN, ARTHUR. The vapour pressures of aqueous solutions with special reference to the problem of the state of water in biological fluids. *Jour. Gen. Physiol.* 14(5): 661-683. 1931.—The vapor pressure depressions of several dilute aqueous solutions (0.03-0.1 *M*) were determined by the thermo-electric method of A. V. Hill, which measured the temp. differences produced by the evaporation of very small quantities of solution from wet filter paper. The probable errors are 0.5-1.0%. In mixed solutions organic substances (urea, sucrose, etc.) gave anomalous results, and even with inorganic salts (LiCl, $CaCl_2$) only approximate additivity of the depressions was obtained. The results with mixtures of gelatin or gum acacia with NaCl or KCl in solution showed that hydration is slight with gelatin at pH 7 and indetectable in gum acacia solutions. Hence those hydrophilic colloids are not strongly hydrated. No change in hydration of the colloids was found on passing from the sol to the gel state in gelatin or in blood.—*D. I. Hitchcock.*

15656. JOCHIMS, J. Das Fadenziehen biologischer Substanzen. Sammelreferat. *Protoplasma* 9(2): 298-317. 2 fig. 1930.—A review is given of the phenomenon of thread formation as described for living and non-living matter, including the protoplasmic threads formed by a plasmolyzed protoplast and the myelin threads produced by lecithin.—*W. Seifriz.*

15658. KRUEGER, A. P., and R. C. RITTER. The preparation of a graded series of ultra-filters and measurement of their pore sizes. *Jour. Gen. Physiol.* 13(4): 409-419. 1 fig. 1930.—A graded series of ultrafilters was prepared, impregnating filter paper with glacial acetic acid solutions of negative cotton in which the latter substance was varied according to the density of the membrane desired. After thorough impregnation, gelation was effected by submersion in sterile water and all traces of acid were removed by repeated washings. The pore sizes of the entire series were determined by measuring permeability to purified sols of known particle sizes and the estimates so obtained were compared with pore diam. calculated from rate of flow data. The pore diam. for any given membrane as estimated by permeability to sols was always some 150 mμ less than that calculated from data on permeability to water. The membranes are useful in determining the particle size of ultramicroscopic viruses. They require no sterilization and are employed in connection with a simple glass ultrafilter apparatus.—*A. P. Krueger.*

15659. LAGRANGE, E. Coagulation du blanc d'oeuf par des agents biologiques. *Compt. Rend. Soc. Biol.* 98 (17): 1527-1529. 1928.—Using cholera vibrio, heat, alcohol, trypsin, pepsin, meat juices, etc., types of coagulation of egg white (1 part in 4 parts distilled H_2O) were studied.

15660. LUDWIG, WILHELM. Permeabilität und Wasserwechsel bei Noctiluca miliaris Suriray. [Permeability and water exchange in N. miliaris.] *Zool. Anzeiger* 76 (11/12): 273-285. 6 fig. 1928.

15661. MONAUNI, JOSEF. Zur Frage der Kaliumdurchlässigkeit der Muskelfasergrenzschicht und ihrer Förderung durch Rohrzucker. *Pflüger's Arch. Ges. Physiol.* 221(6): 800-806. 1929.—The soft, flat, musculature of the abdomen of the ♀ frog (*Rana esculenta*) was stretched across a glass tube filled with isotonic KCl. The conductivity of the cell was then used as a measure of permeability. At 36° C. there was scarcely any ion migration across the membrane. When the tube was placed in a sugar solution, the membrane was per-

meable to K, but this was not due to poisoning of the membrane. If the membrane had been stretched too tightly across the tube the interstices became enlarged through stretching and the membrane was slightly permeable to K. Without undue stretching it was impermeable. Normally, in situ, the muscle fiber membrane would not be stretched and probably would not be permeable to K.—*N. M. Payne.*

15662. **MURATA, M. Über die parenterale Resorption von Kolloiden. III.** *Biochem. Zeitschr.* 226(4/6): 457-461. 1930.—The normal diastase value in 4 rabbit sera was found to be constantly 64 units. Subcutaneous injection of 1280 units each into 2 rabbits did not change the diastase value; nor did intraperitoneal injection of 1280 units into 2 rabbits, 2560 units into 6 rabbits, or 5120 units into 5 rabbits. Intravenous injection of 2560 units each in 7 experiments on 5 rabbits, raised the diastase for 60-180 min., and intravenous injection of 5120 units each into 6 rabbits raised the values for 24 hrs.

15663. **NORTHROP, JOHN H., and M. KUNITZ. Swelling and hydration of gelatin.** *Jour. Phys. Chem.* 35(1): 162-184. 18 fig. 1931.—The swelling, osmotic pressure, viscosity, and syneresis of gelatin gels or sols may be quantitatively accounted for on the following assumptions. Gelatin sols or gels are 2-phase, 3-component systems. The solid phase consists of particles (micellae) of an insoluble ingredient of the gelatin. The liquid phase is an aqueous solution of the "insoluble" fraction and of a "soluble" fraction in water. Each micella is a separate system consisting of an insoluble elastic wall or net-work containing an "internal" liquid phase, which is a solution of the "insoluble" fraction from the wall of the micella and of 1 or more other fractions which have a high temp. coefficient of solubility and for which the walls of the micellae are impermeable. —*Authors' summary.*

15664. **PEDERSEN, KAI O. Temperature stability and denaturation of serum albumin.** *Nature* [*London*] 128(3221): 150-151. 1931.—The aggregation products of heated serum albumin are homogeneous as to electrophoretic movement. Their isoelectric point is pH 5.1-5.3 (cf. pH 4.88 for native serum albumin), and the pH-mobility curve nearly parallels that of native serum albumin. Beyond the stability region (i.e., at acidities>pH 3.8) the smaller particles formed on heating differ in sedimentation constant from those formed from native serum albumin, and the electrophoretic mobility was as that of heat-denatured serum albumin. Serum albumin solutions at pH 3.5, exposed to ultra-violet, are changed; light absorption is increased, odor becomes strong, and other properties are modified.

15665. **ROCHE, JEAN. Sur quelques propriétés physico-chimiques de la globine.** *Arch. Phys. Biol.* 7 (3): 165-179. 3 fig. 1929.—Natural globin, prepared from hog and ox blood by a process involving dialysis at 0°, had an isoelectric point at 7.5 as determined by cataphoresis of 2-8% protein solutions containing 9% NaCl. Its minimum buffer capacity, derived from the point of inflexion of neutralisation curves obtained with HCl and NaOH (*N*/20) and an antimony electrode, occurred at pH 7.6 but varied with the concentration of protein. The denatured protein gave the corresponding values 7.7 and 7.6. Differences in the solubility of the 2 proteins are discussed.—*A. M. Smith.*

15666. **SCHREINEMAKERS, F. A. H. Membrane and osmosis. II.** *Rec. Trav. Chim. Pays-Bas* 50(7/8): 883-899. 3 fig. 1931.—Results of osmosis experiments on aqueous solutions of oxalic, succinic, and tartaric acids, and Na_2CO_3, with parchment, cellophane, and pig-bladder membranes are given. With oxalic acid solutions, water diffused through pig-bladder from the solution towards the pure water at all concentrations and during the entire osmosis. The results of such experiments are deduced from curves expressing the variation of the amounts of solute and solvent absorbed by the membrane with their concentrations in the solution, by postulating the existence of hypothetical sluice gates on opposite sides of the membrane. The sluice type of diffusion may or may not be the same as the stationary type.—*N. F. Burk.*

15667. **TARUSSOFF, B. Über Zellpermeabilität und Anpassungsfähigkeit bei Wassertieren.** *Protoplasma* 9 (1): 97-105. 5 fig. 1930.—Tissue membranes of the Euryalae are readily permeable to water and slightly to salts (1:120). Stenohaline organisms are readily permeable to both water and salts (1:1). The harmful influence of equivalent hypertonic salt solutions does not arise from osmotic pressure but from salt penetration.—*L. S. Moyer.*

15670. **CHROMETZKA, FRIEDRICH, und JIRO ISHIDA. Fermentstudien. I. Vergleichende Enterokinaseanalysen.** *Zeitschr. Ges. Exp. Med.* 67(3/4): 465-474. 1929.—Trypsin obtained from man, dog, pig and ox was combined with kinase from each of the 4 and each trypsin-kinase combination was allowed to act on casein, gelatin, peptone and egg albumin. With casein and gelatin each of the 4 kinases activated each of the 4 trypsins, the homologous combinations being most strongly active in any series. None of the kinases caused trypsin from man or ox to act on peptone, while trypsin from dog or pig was activated by all 4 kinases. The egg albumin experiments with varying concentrations of kinase supported the view that differences in the kinase structures affecting the complex combination of definite molecular groups did not exist. The chemical mechanisms of the various trypsin-trypsinkinase reactions appeared to be similar.—*R. L. Nugent.*

15671. **COSACK, GERT. Aktivierung und Stabilisierung von Pankreasdiastase durch Hämatin.** *Biochem. Zeitschr.* 235(4/6): 469-484. 1931.—In vitro studies of the activating action of alkaline hematin on diastase starch splitting showed that hematin and other Fe-containing blood-pigment derivatives aside from Hb accelerated diastase within the entire range of its action. The acceleration, measured by iodine-starch decolorization (achromatic point), was 6- and 10-fold; measured by sugar formation, 9-fold. Hematin widened the zone of effectiveness of diastase moderately on the acid side, and considerably on the alkaline. Traces of admixed NaCl did not account for the entire action of the preparation, nor did the solvent action of Na_2CO_3 or the Fe contained in hematin molecule. Hematin protected the diastase from heat and especially from destruction by oxygen. This "protective action" was shown also to a slight extent by NaCl; Hb did not protect. The appearance

of hematin-diastase combination on one side and an intimate connection with oxygen on the other was assumed.

15672. **ERDTMAN, HOLGER. Über Nierenphosphatase und ihre Aktivierung. II.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 177 (5/6): 211-220. 3 fig. 1928.—A double precipitation from Liebig's beef extract yielded an activator for the phosphatase found in the kidney. The precipitants were $Ba(OH)_2$ and Pb acetate. The activator was freely dialyzable. The less carbohydrate and protein it contained the more active it was. The purified activator contained large amounts of sulphate and Mg, but was not identified as $MgSO_4$. Dialyzed ash from the kidney itself did not yield a phosphatase activator.—*N. M. Payne.*

15673. **ERDTMAN, HOLGER. Über Nierenphosphatase. III.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 177 (5/6): 231-236. 1928.—The maximal activation of phosphatase by $MgSO_4$ was as great as the maximal by the activator found in Liebig's beef extract. Small amounts of $CaSO_4$, $BeSO_4$, and $ZnSO_4$ did not activate the enzyme appreciably. Zn poisoned the enzyme. The enzyme preparations used differed considerably in strength. Experiments were made to obtain highly active enzyme solution by adsorption on $Al(OH)_3$ or kaolin and eluting with ammonia or secondary sodium phosphate. Kaolin adsorbed the enzyme at pH below 7, with ammonia for the elution. Neither adsorption nor elution was specific. The best adsorbent was $Al(OH)_3$. Elution was difficult from this adsorbent with ammonia but was readily made with secondary sodium phosphate. The purest enzyme preparations were obtained by the last method. Even this did not appear to be quantitative. The activator was possibly $MgSO_4$ but it is held that activation may be more complicated than the simple salt effect.—*N. M. Payne.*

15674. **FROMAGEOT, CLAUDE. Die stereochemische Spezifität der Sulfatase. (Über Sulfatase. XI.)** *Biochem. Zeitschr.* 208 (4/6): 482-489. 1929.—Sulfatase liberated a dextrorotatory p-secondary isobutyl-phenol from the sulphate compound, whereas hydrolysis by heating with HCl of the portion unattacked by the enzyme yielded the laevo-rotatory compound.—*O. Bodansky.*

15675. **GALWIALO, M. J., und R. DOBROTWORSKAJA. Der Einfluss des Eiweisses auf die oxydativen und katalytischen Eigenschaften anorganischer Fermente.** *Biochem. Zeitschr.* 207 (1/3): 146-150. 4 fig. 1929.—The oxidation of guaiac by certain cations (Mn, Pt, Co and Ni), whose effect alone is weak, is increased by the addition of ovalbumin; that of others (Au, Fe, Cu) whose effect is greater is not altered. Boiling the mixture inhibits, but the power is partially restored by grinding with glass. The catalytic effect on alkaline H_2O_2 of Ni, Au, Pt and to a slight extent of Mn salts is increased while that of Fe, Cu and Co salts is inhibited by the presence of protein. Its action is attributed to a protective colloid effect.—*G. S. Eadie.*

Enzymo-chemical investigations from the laboratory of R. Willstätter.] (Sonderausgabe aus: Ergebnisse der Physiologie. Band 27.)** iv + 146p. 10 fig. J. F. Bergmann: München, 1928. Pr. 12.60 M.

15677. **GROLL, J. TEMMINCK. Het eindpunt der Tryptase-werking.** *Pharm. Weekblad* 68 (6): 109-121. 1931.—The extent of hydrolysis of casein and gelatin by trypsin preparations (hog pancreas dried and freed of fat according to Willstätter) was studied. About 20% of the N was converted in one week in amino-acid-N (Sorensen formol method). After 2 months the hydrolysis went as far as 30%, but this further increase could not be imputed to the enzyme, because the control without enzyme behaved similarly. Addition of new enzyme after 1 week had no influence. The enzyme was not inactivated after 1 week but could hydrolyse fresh substrate. This could be repeated 4 times. The purity of the enzyme had no influence. After purification (adsorption and elution according to Willstätter) the results were the same. pH and concentration of the enzyme also did not influence the results. The hydrolysis could be continued only by the addition of another enzyme (proteolytic enzyme from yeast).—*J. T. Groll.*

15684. **McHENRY, E. W., and GERTRUDE GAVIN. Studies on histaminase.** *Trans. Roy. Soc. Canada, Sect. 5: Biol. Sci.* 25: 101-109. 5 fig. 1931.—Beef kidney, defatted and desiccated with acetone and ether, was used as a source of histaminase. From this, extraction with phosphate buffer, pH 7.2, gave larger yields than did a number of other solvents. The aqueous solution was unstable. It could be concentrated in vacuo below 50° C. Histaminase was quantitatively precipitated by ammonium or magnesium sulfates. Time-rate measurements of the histamine-histaminase reaction showed the velocity constant to be logarithmic and the reaction to be unimolecular. It was probably oxidative.—*E. W. McHenry.*

15685. **MAJOROW, S. Über das Vorhandensein von Urease im Organismus der Tiere.** *Biochem. Zeitschr.* 241 (1/3): 228-232. 1931.—Using 3 drops phenolphthalein as indicator with 2 cc. of tissue extract and 2 cc. of 5% urea solution, urease was found in hypophysis, stomach, suprarenals, and ovary but not in kidney, spleen, liver, lung, or blood serum of the dog; that of the gastric mucosa was inactivated at 60°. The gastric mucosa of the cat and cow but not of the rabbit, pig, or sheep contained urease; the pylorus of the cow and the liver, spleen and kidneys of both cow and cat contained none.

15686. **[MINKER-BOGDANOVA, E. T., and G. D. OBRAZTSOV.]** МИНКЕР-БОГДАНОВА, Е. Т. и Г. Д. ОБРАЗЦОВ. О липазе крови при сахарной нагрузке. **[Blood lipase following sugar administration.]** [German summary.] Русский Физиологический Журнал имени И. М. Сеченова (*Russ. Jour. Physiol.*) 13 (2): 204-209. 1930.—Blood was tested for sugar (Hagedorn-Jansen's method), fats (Bang's method), and lipase, 5, 15, 30, 45, 60, 90, 120, 150, and 180 min. after sugar administration per os to children. Lipase was determined in hemolyzed blood by measuring the quantity of fatty acid formed

in a 1% monobutyrin solution in 24 hrs. in a thermostat. The maximum changes in blood lipase coincided with the maximum changes in the sugar and fat contents of the blood; though the character of these changes was not uniform. Parallel and inverse relations were both observed.—*S. A. Corson.*

15687. MOELWYN-HUGHES, E. A. The enzymic hydrolysis of phloridzin. *Jour. Gen. Physiol.* 13(6): 807-817. 1930.—Judging by the velocity of hydrolysis by acids and also by the energy of activation, phloridzin resembled the γ-fructosides more closely than the normal glucosides. Emulsion was without action on phloridzin at various values of pH and temperature, but saccharase hydrolyzed it. Phloridzin sugar differed from glucose in its specific rotation and in its action towards *Bacillus pestis.*—*E. A. Moelwyn-Hughes.*

15688. MÜHLBOCK, O., und C. KAUFMANN. Die Wirkung der Hormone, insbesondere des Thyroxins, auf die fettspaltenden Fermente. *Biochem. Zeitschr.* 238 (4/6): 377-390. 1931.—Using the Rona-Michaelis drop method, the actions of prolan, prephyson, pituigan, myopituigan, vasopituigan, pitocin, pitressin, orasthin, tonephin, thyroxine (Henning) thyroxine (Laroche), crystallized thyroxine, insulin (Wellcome), insulin (Kahlbaum), kallikrein, synthetic suprarenin, organic suprarenin, progynon, folliculin, hogival, ovoglandol, luteoglandol, and theelin were tested on the lipases of fatty tissue, pancreas, liver, placenta, and serum. Only thyroxine had a pronounced action inhibiting fatty tissue, placenta, pancreas, and hepatic lipase; prephyson exerted a slight inhibition on lipolysis. Serum lipase was slightly inhibited by various hormones; kallikrein had a marked action. The minimal dose of thyroxine with Warburg, Rona, and Lasnitzki's method was a dilution of $1:10^7$; insulin and progynon $1:10^6$. Lipase was always inhibited; inversion of action did not occur with changed concentrations. By determining the coefficient of inhibition according to Michaelis-Rona it was found that inhibition of enzymatic action in thyroxine was due to an affinity of the hormone for the enzyme. Enzymatic fat synthesis was not affected by thyroxine.

15689. MÜLLER, D. Glykoseoxydase. IV. Glykoseoxydase aus Aspergillus niger. Verhalten gegen Disaccharide (Maltoseoxydase), Glykuronsäure und Äthylalkohol; Versuche mit Methylenblau und Monojodessigsäure. *Biochem. Zeitschr.* 232(4/6): 423-434. 1931.—Glucose-oxidase preparations (G.) had no action on lactose. Saccharose was hydrolyzed and the glucose formed oxidized to gluconic acid by G. If the enzyme was first heated to 70° for 30 min. so that the saccharase but not the G. was destroyed, the saccharose was not attacked. G. acted on maltose but the action, unlike that of saccharase, was in part direct oxidation of maltose by an enzyme that must be called maltoseoxidase, not G. Maltoseoxidase was more thermolabile than G. and with atmospheric O oxidized maltose to a non-reducible compound. G. did not act on glycuronic acid or on ethyl alcohol. According to the present investigation it attacked only compounds with the same configuration as glucose in atoms 1 and 6. Monoiodo-acetic acid inhibited the action of G. less than that of zymase. Of the known dehydrases, G. contained only malic acid dehydrase, for only malic acid accelerated the reduction of methylene blue by G., glucose, fructose, gluconic acid and other compounds inhibited the reduction.—*Author's summary (transl.).*

15690. NORTHROP, JOHN H. Crystalline pepsin. I. Isolation and tests of purity. *Jour. Gen. Physiol.* 13 (6): 739-766. 1 fig. 1930.—The preparation of a crystalline protein from commercial pepsin preparations which had powerful peptic activity was described. The composition, optical activity, and proteolytic activity of this protein remain constant through 7 successive crystallizations. No evidence for the presence of a mixture or of a solid solution was found in a study of the solubility of the protein in a series of different salt solutions, nor from the diffusion coefficient or from the rate of inactivation. These results indicated that the material is a pure substance or possibly a solid solution of 2 or more substances having nearly the same solubility in all the various solvents studied. It seemed reasonable therefore that the possibility of a mixture must be limited to a mixture of proteins, and it is concluded that pepsin itself is a protein.—*J. H. Northrop.*

15691. NORTHROP, JOHN H. Crystalline pepsin. III. Preparation of active crystalline pepsin from inactive denatured pepsin. *Jour. Gen. Physiol.* 14(6): 713-724. 1931.—Pepsin solutions which had been completely denatured and inactivated by adjusting to pH 10.5 recovered some of their activity when titrated to about pH 5.4 and allowed to stand at 22° C. for 24-48 hrs. Control experiments showed that this inactivation and reactivation were probably not due to the effect of any inhibiting substance. A method of isolation of the reactivated material was worked out. The reactivated material recovered in this way was a protein with the same general solubility, the same crystalline form, and the same specific proteolytic activity as the original crystalline pepsin. This furnished additional proof that the proteolytic activity is a property of the protein molecule.—*J. H. Northrop.*

15692. NORTHROP, JOHN H. The presence of a gelatin-liquefying enzyme in crude pepsin preparations. *Jour. Gen. Physiol.* 15(1): 29-43. 1931.—A protein fraction was isolated from crude pepsin preparations which was about 400 times as active as crystalline pepsin in the liquefaction of gelatin. The activity as measured by the digestion of casein, edestin or egg albumin was less than that of crystalline pepsin. It was more resistant to alkali than the crystalline pepsin.—*J. H. Northrop.*

Zeitschr.* 239(4/6): 430-433. 2 fig. 1931.—Even in the absence of buffer salts a pronounced temp. optimum for pancreatin action on collagen was found. By increasing markedly the proportion of active enzyme to collagen the optimum shifted to a higher temp.

15698. SUZUKI, KORETAKA. Konstitution der Polypeptide und proteolytische Fermente. *Jour. Biochem. Tokyo* 13: 57-80. 1931.—Pepsin, papain, papain-HCN, trypsin, and trypsin-kinase exerted no hydrolytic effect upon glycyl-glycyl-l-asparagine, glycyl-glycyl-l-asparaginic acid, glycyl-dl-asparagyl-glycine, dl-asparagyldiglycin, or dl-asparagyldi-l-tyrosine in 120 hrs. Erepsin attacked all but the last named. The pH of the various solutions was adjusted to the optimum values for action of the various enzymes.—*J. S. Caldwell.*

15699. THUNBERG, T. The hydrogen-activating enzymes of the cells. *Quart. Rev. Biol.* 5(3): 318-347. 1930.—A review of Thunberg's contributions on cellular oxidations, which started with the discovery of the

succinic acid oxidizing enzyme acting on muscle tissues. He named this and other similar enzymes "dehydrogenases." They are specific for every substrate. Speaking of the final fate of the consumed O and of the origin of the O in the expired CO_2, he considers that none of the O consumed in the general metabolism is found in the expired CO_2. The catabolism of the foodstuffs takes place in a series of continuous dehydrogenations carried out by a series of dehydrogenases. When O is present the H split off by the dehydrogenases is transported to this O with formation of water. The oxidation catabolism of the foodstuffs is characterized also by 2 other processes: addition of H_2O, and the splitting off of CO_2. The foodstuffs take part in the intermediate metabolism because of their actual or potential content of H. Although the C is never directly oxidized in the metabolism, its energy is made available through water addition and the splitting off of H and its oxidation. The O is used for the oxidation of the H which is activated by the dehydrogenases and given over to the O in activated form. The O consumed during the respiration is transformed into water. H_2O_2 must be the first or at least the most important product of this reaction between H and O. Through the action of catalase half of the O of the H_2O_2 is liberated and can thus function as H acceptor once more. Thus the catalase is an enzyme which renders possible a more economical use of O. The O in the expired CO_2 does not originate from the O in the atmosphere but came from other sources (O originally contained in the molecules of the foodstuffs, O of the water molecules added to the C chains).—*E. S. G. Barron.*

15700. TOMIOKA, TOKUSABURO. Ferment action and ion concentration. 1. On the destruction of amylase by acids. *Japanese Jour. Gastroenterol.* 1(3): 158-168. 1929.—The optimal pH for pancreatic amylase is 6.3-6.9; the destruction by acids depends not on the nature of the acid, but on the pH; the course of destruction describes a hyperbola. The fact that at 3 pH zones: 1.5, 4.4 to 4.9, and over 6.0, amylase was less sensitive to destruction than elsewhere indicated that it is a complex of 3 enzymes.—*O. Bodansky.*

Infektionskrankh.* 111(5): 703-710. 1 fig. 1930.—A method is described by which unipolarity of the atmospheric ions may be demonstrated in a closed space. In 12 series of experiments no effect of atmospheric ionization and unipolarity could be demonstrated on human blood-pressure, pulse rate, respiration frequency or physical endurance.

15705. BERGER, EVA. Unterschiedliche Wirkungen gleicher Ionen und Ionengemische auf verschiedene Tierarten. (Ein Beitrag zur Lehre vom Ionenantagonismus.) *Pflüger's Arch. Ges. Physiol.* 223(1/2): 1-39. 1 fig. 1929.—The effect of single salts (NaCl, KCl, $MgCl_2$ and $CaCl_2$) on length of life, locomotion, heart beat and other physiological phenomena was compared with that of a solution of artificial sea water and with an isotonic NaCl solution on *Daphnia magna, Cyclops coronatus, Tinca vulgaris* and Batrachian larvae. *Colpidium,* a protozoan, was so resistant to changes in osmotic pressure and to toxic salt solutions that it was unsuitable for a study of ion antagonism. *Spirostomum ambiguum,* another protozoan, was more sensitive to osmotic changes. *Tinca vulgaris* could live in much more dilute solutions of artificial sea water (51 cc. NaCl, 1.1 cc. KCl, 3.4 cc. $MgCl_2$, 2.2 cc. $MgSO_4$ and 1.2 cc. $CaCl_2$ was the original sea water solution) than the other species studied. Each individual cation had a characteristic action on *Daphnia.* NaCl at first quickened the heart beat, and caused the animal to swim rapidly. After 1100 minutes the organism became paralyzed; after 2320 minutes the heart beat ceased and the shells opened. The heart stoppage was irreversible. KCl had a short but very pronounced stimulation effect during which time the animals swam in circles. After 38 minutes the animals became paralyzed in tetanic condition, with hearts in systole, and shells closely shut. Return to normal was accomplished when animals were placed in artificial sea water 3-5 min. $MgCl_2$ and $MgSO_4$ were only quantitatively dissimilar. $MgCl_2$ paralyzed more quickly. After paralysis the heart was in systole. $CaCl_2$ produced effects similar to those of NaCl. The heart stoppage was irreversible. The shells were closed. On tadpoles NaCl had no significant stimulating effect. The tail was the last locomotory organ to lose its function. The heart beat after respiration ceased. KCl produced marked tetanic movements of the tail. $MgCl_2$ produced an early period of stimulation followed by a gradual slowing down of the heart. The heart stopped beating in diastole. In only a few cases were the effects of $MgCl_2$ reversible. $CaCl_2$ had first a stimulatory effect followed by a paralyzing one. The heart stopped irreversibly in diastole. Each ion also had a characteristic effect on the fish. NaCl produced paralysis after a short period of stimulation. Fish died in limp condition with gill covers open. KCl produced an intense irregular stimulation followed by a paralyzing action. Fish died with heart large and gills red. $MgCl_2$ produced a paralysis. In death, the gill covers were opened slightly. $CaCl_2$ produced no stimulation but disturbed the rhythm of heart beat and respiration. In death the heart was small and systolic. As compared with length of life in artificial sea water as standard, the length of life in any one salt was distinctly shorter. The longest life length was observed in NaCl for *Daphnia magna, Cyclops coronatus,* and Batrachian larvae; in $CaCl_2$ for *Tinca vulgaris.* When binary mixtures were used, Batrachian larvae lived longer when an univalent cation was predominant. *Daph-*

nia lived longer in a binary solution of Na plus another salt if Na predominated; but in solutions containing K, it lived longer if there was more Ca or Mg than K in the solution. The optimum for *Tinca* required that a bivalent ion predominate. The effect of ternary solutions was tried only on *Daphnia magna* and Batrachian larvae. In general it was found that the more Mg was present in the solution, the more of a depressant it became. In quaternary solutions the optimum life length and physiological condition was produced when the 4 salts used were present in equimolar proportions. It is concluded that no general rule as to how a given ion acts can be laid down, since the effect of each ion differs from species to species and also depends on whether it acts singly or in mixtures.—*N. M. Payne.*

15706. CHANOZ, M., et G. GLUZET. Conductivité électrique et viscosité des dissolutions aqueuses. Freinage inégal des ions constituants. *Compt. Rend. Soc. Biol.* 100(14): 1205-1207. 1929.—To dilute solutions of KCl, NaCl, NaOH, HCl, H_2SO_4, Na_2SO_4 $CuCl_2$, etc., were added solutions of pure saccharose, glycerine, agar-agar and gelatine, the conductivity and the viscosity of the solutions being determined before and after the additions. From a study of the curves obtained the authors conclude that the restraining influence of increased viscosity does not act equally on anion and cation. No curves are given.

15707. EISENBERG-HAMBURG, E. L'influence des sels de strontium sur les mouvements du Paramaecium caudatum. Le rôle des sels de calcium et de la concentration en ion hydrogène. [In French and Polish.] *Acta Biol. Exp. [Warsaw]* 4(11): 261-277. 1930.—A characteristic reaction to $SrCl_2$ can be observed, persisting for several weeks in non-toxic solutions (0.00167-0.01337%). The number of movements increases with the concentration of non-toxic solutions, but decreases in toxic solutions. Alkalinity increases the intensity of the reaction. Experiments with different salts of Sr showed that the number of movements depends on the anion, but that their intensity is independent of it. The reaction can be annulled by the addition of $CaCl_2$ and of culture liquid. The salts of Ba, Rb, and Cs exert sometimes an influence analogous to the salts of Sr.—*E. Eisenberg-Hamburg (transl. by H. C. Wood).*

15708. GANASSINI, DOMENICO. Le funzioni dello zinco in biologia. [Function of Zn in biology.] *Arch. Ist. Biochim. Ital.* 3(2): 131-138. 1931.—Inorganic and organic basic Zn salts and the hydroxide of Zn behave in alkaline medium like the peroxidases and oxidases, as direct or indirect oxidative agents. In such an oxidase system the basic Zn salt should act binding the atmospheric O_2 (like an oxigenase) and then setting free activated O (like a peroxidase). The oxidative function of Zn, together with its hydrolytic activity and its constant occurrence in animal tissues and fluids, could be invoked to explain the splitting of nucleic acids and the formation of lysocithin from lecithin by cobra venom.—*M. Comel.*

15710. HEILBRUNN, L. V., and KATHRYN DAUGHERTY. The action of chlorides of sodium, potassium, calcium, and magnesium on the protoplasm of Amoeba dubia. *Physiol. Zool.* 4(4): 635-651. 1931.—Specimens were immersed in dilute solutions of NaCl, KCl, $CaCl_2$, $MgCl_2$, and NH_4Cl, and determinations of protoplasmic viscosity were then made by the centrifuge method. Na and K ions markedly increase the protoplasmic viscosity, Ca and Mg decrease it. The behavior of Amoeba protoplasm toward the common cations is thus similar to the behavior of various other types of protoplasm. When amoebae are immersed in NH_4Cl there is apparently an entrance of ammonia or NH_4OH and this produces a secondary effect.—*Authors (courtesy Wistar Bibl. Serv.).*

15711. HELFF, O. M. Toxic and antagonistic properties of Na, Mg, K, and Ca ions on duration of life of Cambarus clarkii. *Physiol. Zool.* 4(3): 380-393. 1931.—The effects of pure solutions of NaCl, KCl, $MgCl_2$, and $CaCl_2$ representing a wide range of molecular concentrations were determined. The average sequence of toxication effect was determined as K > Ca > Mg > Na. The possible antagonistic properties of small amounts of other ions in minimizing the toxicity of pure NaCl, KCl, $MgCl_2$, and $CaCl_2$ solutions were also determined. In general, all ions tested exhibited definite antagonistic effects, which varied with the nature of the pure toxic salt solution and the relative proportions of antagonistic ions added. Solutions based on Dohrn's analysis of *Astacus* blood proved lethal, while those based on Griffith's analysis were non-toxic. Solutions based on seawater analyses (McClendon's solution, Van't Hoff's solution, and Back's solution) all proved decidedly lethal. The results are discussed in general and their bearing on future work involving the effect of various ions on crayfish respiration is indicated.—*Author (courtesy Wistar Bibl. Serv.).*

15712. KISCH, BRUNO. Zur Kenntnis der Wirkung verschiedener Ca-Salzkonzentrationen auf das Froschherz im Frühsommer. *Pflüger's Arch. Ges. Physiol.* 221(4): 469-473. 3 fig. 1929.—It has previously been found that the heart of *Rana esculenta* has a higher Ca requirement in summer than in winter. The author found that this increased need of Ca began in the end of May and disappeared by July. The frequency of the heart beat in different Ca solutions was not altered as much as the amplitude and rhythm. The Ringer's solution that was used had the following composition: 0.65% NaCl, 0.002% KCl, 0.005% NaH_2PO_4, 0.1% $NaHCO_3$ and in the Ca rich solution 0.03% $CaCl_2$, in the Ca poor solution 0.02% $CaCl_2$.—*N. M. Payne.*

15713. KISCH, BRUNO. Antagonismus und Synergismus der Wirkung von Mg- und Ca-Salzen am Herzen. *Pflüger's Arch. Ges. Physiol.* 221(4): 474-477. 2 fig. 1929.—When the frog heart (*Rana esculenta*) in early summer condition was perfused with a Ca poor Ringer's solution, addition of Mg took the place of Ca. However in the fall, Mg added to a Ca-free perfusate scarcely altered the contractility of the heart.—*N. M. Payne.*

15714. KLOBUSITZKY, D. v. Einfluss der Wasserstoffionenkonzentration auf die Salzflockung der Serumeiweisskörper. III. *Biochem. Zeitschr.* 223(1/3): 120-129. 1930.—The lowest flocculating strength of NaCl, Na_2SO_4, $(NH_4)_2SO_4$, and $MgSO_4$ solutions was tested on horse sera, electrodialyzed serum albumins and globulins in acid and alkaline medium. The first clouding in acid serum occurred with 1 *N* NaCl and Na_2SO_4, 1.5 *N* $(NH_4)_2SO_4$, and 3 *N* $MgSO_4$ solutions; 2 *N* Na_2SO_4, 3 *N* $(NH_4)_2SO_4$ and 3.5 *N* $MgSO_4$ was required to obtain the same reaction in neutral serum; NaCl had no flocculating action even in 3.5 *N* solution. In acid globulin mixtures the salt concentrations were the same as with sera except $MgSO_4$, which was active at 2 *N*. The electrodialyzed albumin solutions showed the first flocculation with 1.5 *N* NaCl, 1 *N* Na_2SO_4, and 2.5 *N* $(NH_4)_2SO_4$ solutions. $MgSO_4$ was entirely inactive at 3.5 *N*. In alkaline medium only $(NH_4)_2SO_4$ and $MgSO_4$ acted on whole serum. These phenomena can in part be traced to secondary ion effects, in part to protective colloid actions.—*Author's summary (transl.).*

15715. KRÜGER, FRIEDRICH. Untersuchungen über die Ursachen des Todes des Stichlings (Gasterosteus aculeatus) in reinen Chlornatriumlösungen. *Zeitschr. Wiss. Biol. Abt. C. Zeitschr. Vergleich. Physiol.* 7(4): 696-735. 4 fig. 1928.—All concentrations of pure NaCl between 1 *M* and 0.05 *M* proved poisonous to the stickleback. In distilled water the fish lived no longer than 15 days. NaCl solutions of 0.4 *M* or less could be detoxicated by antagonistic ions. Ca and K proved necessary to prolongation of life for 1-2 mos. Whether Mg was likewise necessary to life did not appear certain, but its addition was always helpful. Pure NaCl solutions of high concentrations caused extensive destruction of the epidermis. That NaCl permeates into the fish was shown by increased Cl excretion (also present in pure Na_2SO_4

solutions), and abnormal expansion of the melanophores and alteration of the nuclear structure of the blood cells in the dying fish, etc. The loss of wt. was less after 1 hr. in pure NaCl solutions of high concentrations than in like concentrations of balanced solutions; therefore death in pure NaCl solutions is not due to loss of water by osmosis, but is attributed to injury to musculature and nervous system.—*From author's summary (transl. by N. M. Payne).*

15717. **LEPESCHINSKAJA, O. Der Einfluss von Elektrolyten auf die Epithelzellmembran.** *Protoplasma* 8: 492-507. 3 pl. 1930.—Under the influence of electrolytes the cell membrane forms bridges, canals, vacuoles, granules, and becomes quite homogeneous or fibrous.—*W. Seifriz.*

15718. **MOORE, A. R. Fertilization and development without membrane formation in the egg of the sea urchin, Strongylocentrotus purpuratus.** *Protoplasma* 9 (1): 9-17. 3 fig. 1930.—Non-electrolytes, such as urea, render unfertilized sea urchin eggs incapable of membrane formation. Such eggs when fertilized segment and form irregular clusters of cells and not blastulae. They are, however, held together by protoplasmic bridges. Ions of alkaline earth metals added in sufficient amounts to the solution of non-electrolyte protect the egg against this loss of capacity. Since Ca and Mg are equipotential in action it is assumed that this is a valence effect.—*L. S. Moyer.*

15719. **MOORE, A. R. Fertilization and development without the fertilization membrane in the egg of Dendraster eccentricus.** *Protoplasma* 9(1): 18-24. 5 fig. 1930. —Non-electrolytes render unfertilized *Dendraster* eggs incapable of membrane formation. After fertilization, cell plates are formed instead of blastulae. Mg, Ca, Sr and Ba added to the non-electrolyte inhibit this loss of capacity in effect roughly proportional to their valence. Fertilized eggs kept for a short time in non-electrolytes or in *M*/2 NaCl or sea water at pH 4 lose their membranes and form cell plates. Bivalent ions prevent this. Ca, Sr and Ba are equal in effect and 8 times more effective than Mg. In early stages, cell bridges are seen but later hyaline processes join the cells. Cells in plates undergo a rhythm of extension and contraction.—*L. S. Moyer.*

15720. **OGAWA, JUNTARO. Über die Reaktion der Gewebe. IV. Studien über intrazelluläre Wasserstoffionenkonzentration der Entamoeba histolytica und Entamoeba coli.** *Zentralbl. Bakt. I. Abt. Orig.* 114(1/2): 68-81. 1929.—The endoplasm of the vegetative form of *E. histolytica* has a pH of 6.0-7.0. The ectoplasm is not colored by indicators as it is in *E. coli* in which pH 6.5-7.0 is found. The pH of the nucleus is usually slightly higher than the protoplasm (endoplasm and ectoplasm) pH 6.6-7.2. The pH values of the cysts were somewhat lower than in the vegetative forms and the technic offered greater difficulties. Changing the pH of the medium from 5.2 to 8.0 did not influence the intracellular pH.—*N. Kopeloff.*

15721. **POPOW, N. A., und A. A. KUDRJAWAZEW. Zur Frage nach der Einwirkung von Ionen auf die Atembewegungen des isolierten Froschkopfes.** *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 10(3): 456-464. 2 fig. 1929.—The isolated frog head preparation is capable of responding to variations in composition of perfusion fluid by changing the character of its respiratory movements. Normal or Ca-free Ringer's solution may cause their production or intensification, followed by a period of rest; removal of Ca from the perfusion fluid may produce a decrease or a complete cessation of these movements. If one of these combinations evokes a positive response, the other combination, acting on the same preparation, may frequently produce no effect or an inhibitory one. In general, therefore, there is no evidence here for ascribing an inhibitory influence on the respiratory center to doubly charged ions and an excitatory effect to singly charged ions.—*F. Hollander.*

15722. **PRATOLONGO, U. Principii di acidimetria applicata. Le applicazioni dei nuovi metodi acidimetrici alla chimica agraria, analitica, biologica, bromatologica e industriale.** 221p. 2 col. pl., 26 fig. Ulrico Hoepli: Milano, 1931.

15723. **RUNNSTRÖM, JOHN. Zur experimentellen Analyse der Wirkung des Lithiums auf den Seeigelkeim.** *Acta Zoologica* 9(3): 365-424. 24 fig. 1928.—Materials: chiefly *Paracentrotus lividus;* some experiments with *Psammechinus microtuberculatus* and *Sphaerechinus granularis.* Immediately after fertilization eggs were put into sea-water diluted with various proportions of isotonic electrolytes, using dilution with NaCl as a control. Two sorts of plasmolysis occur: "eckig," with corrugated surface and "konvex" with smooth surface. The former is interpreted to mean heightened, the latter lowered, viscosity. Electrolytes are effective in producing "eckig" plasmolysis in the order: Ca, Mg, Li, Na, K. It is concluded that K is most effective, Ca least effective in decreasing the viscosity of the cortex. In seawater with added Li, development is slowed; with added K, accelerated. K swells, Li precipitates. This was verified with the dark field microscope which shows in Li-seawater, a widening of the yellow girdle due to lowering of the colloid solubility of the lipoid and a turbidity of the protoplasm, which shown, on sectioning fixed entoderm cells, to result from a coarsening of the granulation. From theoretical considerations by the use of Donnan's equilibrium it is concluded that Li acts by penetrating the cell. K antagonizes Li and prevents both developmental Li abnormalities and colloidal changes. Abnormalities in Li and various combinations of Li and K are described; Li affects primarily the animal region of the embryo. Mg and Ca antagonize Li by hindering its penetration into the cells; K prevents the precipitation of colloids by Li. SCN is not antagonistic to Li. In attempting to imitate Li effects with other agents, CO was found most similar. In mixtures of 97% CO and 3% O_2 no development occurs in the dark but in the light larvae similar to Li larvae are obtained, with greatest inhibition in animal region and exogastrulation, CO inhibits oxidation and this causes aggregation of the colloids, which is also the chief effect of Li. Li and CO abnormalities result primarily from the inhibition of the animal region.—*L. H. Hyman.*

15724. **THORNER, MELVIN W. Recovery of the heart beat of Fundulus embryos after stoppage by potassium chloride.** *Biol. Bull. Marine Biol. Lab.* 56(3): 157-163. 5 fig. 1929.—The heart-beat of eggs blocked completely by KCl recover in both sea and distilled water although the 2 recovery processes are dissimilar. In sea water the duration of the recovery period is directly proportional to the concentration of KCl and to the time of immersion in KCl. A constant amount of KCl is required to block the heart-beat completely. The recovery of eggs in distilled water was studied with the aid of electrical conductivity.—*Author's summary.*

15725. **YAGLE, ELIZABETH M. Permeability of egg membranes. Water exchange through the egg membranes of Fundulus.** *Protoplasma* 9(2): 245-268. 14 fig. 1930.— The effect of NaCl, KCl, and $CaCl_2$ in increasing permeability of the *Fundulus* egg for water seems to be due to their cation, the order of effectiveness being Na, K, Ca. Marked physiological differences in the membranes of eggs in various developmental stages are indicated. The effect of the pH of the solution on the rates of water exchange is of little significance.—*W. Seifriz.*

15726. BUCCIANTE, LUIGI. Sulla sopravvivenza alle basse temperature (fino a −25°) dei vari tessuti di embrioni di pollo di cui fu interrotta l'incubazione. [Survival at low temperatures (to −25°) of tissues of chick embryos the incubation of which has been interrupted.] [With German summary.] *Arch. Exp. Zellforsch. bes. Gewebezücht. (Explantation)* 11(3): 397-423. 1931.—While embryos fail to develop if exposed at the 6th-12th day of incubation to low temps., most of the tissues survive; migration and partition of cells takes place from explants of frozen embryos cultivated by the usual methods in plasma. If the embryos were preserved at 0°, the tissues survived longer than the tissues of embryos preserved at 15-20°—just the opposite of what occurs in cultures from embryos the incubation of which has been interrupted. The shorter the time the embryo is preserved at 0°, the better the explants thrive, indicating that only a limited number of the cells of the embryo survive under such circumstances. Not all embryos attain the extreme limits of survival; the others survive for various periods. Epithelial and connective tissue cells of the skin survive the death of the embryo as an organism for the longest period. In some organs (e.g., skin), the cells of various character have the same survival period; in others (e.g., spleen), the survival period of the cells of different character is different. Survival of tissues was observed at very low temps.,—as low as −25°. This extreme limit was reached only by cells of certain tissues (skin, cornea); survival of other tissues was observed when kept for a long time at −10° to −14°. The survival of embryonic tissues at low temps. is a form of latent life comparable to that obtained by exsiccation.—*Author's summary (transl.)*.

15727. BUCCIANTE, LUIGI. Resistenza dei tessuti di embrioni di pollo a temperature molto basse. [Resistence of tissues of chick embryo to very low temperatures.] *Monitore Zool. Ital.* 40(11/12): 313-316. 1930.—Chicken embryos of 7-8 days were exposed to temperatures ranging from 20° to −25° for various periods, and parts of various tissues tested for life by tissue culture. Different tissues differed greatly in their resistance to cold. Skin epithelium, the most resistant, lived 28 days at 0°, 24 days at 20°, and 3 hrs. at −25°.—*W. C. Boyd.*

15728. BÜNGER. Results of investigations respecting artificial ultraviolet light irradiation of dairy cows. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 1): 165-166. 1931.—A summary.

15729. CHOUCROUN, NINE. On the hypothesis of mitogenetic radiation. *Jour. Marine Biol. Assoc. Unit. Kingdom* 17(1): 65-74. 2 pl., 3 fig. 1930.—Eggs of sea urchin in quartz vessels exposed to a revolving culture of *Bacillus tumefaciens* through the quartz developed abnormally only when the vessels were merely covered and not hermetically sealed. Sea water exposed without eggs causes abnormalities in eggs added after exposure. Hermetically sealed vessels of sea water were, however, not active. The author believes that the abnormal effects are due to chemical impurities, creeping over the surface of the vessels and, in the case of the covered ones, entering the water. These are excluded by the seal. Mitogenetic radiation is not present in this experiment.—*L. S. Moyer.*

15730. HARVEY, E. NEWTON, and G. I. LAVIN. Reduction of oxyluciferin by atomic hydrogen. *Science* 74(1910): 150. 1931.—Some luminous animals, e.g., *Cypridina* (Crustacea), contain luciferin which oxidizes to oxyluciferin in aqueous solution containing O. During attempts to excite luciferase to luminescence by energy of recombination of H atoms, the authors observed that dry oxyluciferin can be reduced to luciferin, confirming results obtained by reducing oxyluciferin in aqueous solution, and rendering it quite certain that the luciferin-oxyluciferin change is a dehydrogenation-hydrogenation reaction. When dry luciferase and luciferin are exposed to low concentration atomic H there may be observed at times a faint bluish glow which breaks into incandescence on raising the atomic H concentration. The faint glow of *Cypridina* may be a luminescence or a low temp. incandescence. Willemite, etc., show undoubted luminescence in atomic H.

15731. HOLLAENDER, ALEXANDER, and EUGENE SCHOEFFEL. Mitogenetic rays. *Quarterly Rev. Biol.* 6(2): 215-222. 5 fig. 1931.—A review.

15732. HUMPHRIS, FRANCIS HOWARD. Ultra-violet and other rays: their uses in health and disease. (Macmillan's Sixpenny Self-Help Library, Vol. 10.) 127p. Macmillan & Co., Ltd.; Eyre & Spottiswoode, Ltd.; London, 1930. Price 6d.

15733. LAKHOVSKY, GEORGES. L'oscillation cellulaire. Ensemble des recherches expérimentales. 319p. 8 fig. G. Doin & Cie; Paris. 1931.—This is a reprint, or translation and reprint, in French, of 33 papers from various French and Italian journals, of articles by the editor and others, dealing with the relations of radiant energies to plant and animal life, and to their clinical effects upon man, especially in cancer. The editor contributes an introduction.—*C. A. Kofoid.*

15734. LIEVENDAG, ESTER. Die Wirkung der Bestrahlung auf die Blutmenge. *Pflüger's Arch. Ges. Physiol.* 227(5): 546-548. 1931.—After intensive irradiation with a carbon arc lamp no increase in blood volume occurred in 6 healthy, non-anemic dogs.

15735. MIESCHER, G. Das Problem des Lichtschutzes und der Lichtgewöhnung. *Strahlentherapie* 35(3): 403-443. 12 fig. 1930.—Ultraviolet light is absorbed by the cornea in proportion to the thickness of this tissue, which explains the variations of the sensitivity to light of different regions of the body. Histological study of the reaction produced by light shows a uniformly progressing penetration proportional to the dose and only influenced by differences of the corneous layer. Resistance to the reaction of light is built up by increasing the thickness of the corneous layer. It is, therefore, closely connected with increased keratine formation. Pigment also absorbs readily the u.-v. rays (Dorno rays), but on account of its location in the deeper layers of the skin it is presumably of less importance as a protective mechanism.—*W. F. von Oettingen.*

15736. SCHREIBER, H., und A. LUNTZ. Mitogenetische Strahlung. *Tabulae Biologicae Periodicae* 1(3): 285-299. W. Junk: Berlin, 1931.—The known sources and detectors used in a study of the rays are tabulated with the + or − results, brief comments, and the name of operator (from a list of 116 references).

15737. VIGNAL, M. Les rayons ultra-violets et infra-rouges. 240p. 2 pl. 26 fig. Gaston Doin et Cie: Paris, 1930. Price 30 fr.—Addressed chiefly to physicians, this book presents a critical summary, not too technical, of modern knowledge of ultra-violet and infra-red rays. Theories as to the nature of light and similar radiations are discussed in the introduction. In chapter 1, ultra-violet and infra-red rays are defined, and their physical and chemical properties and biological effects are discussed, and there is given a résumé of the action of irradiated substances (vitamines, etc.) and of the hypotheses of the general effect of ultra-violet rays. The same chapter discusses infra-red, antagonism between ultra-violet and infra-red, and the biological effects of infra-red. Chap. 2 treats of the production of these

rays, dosage, and measurement of intensity. Chap. 3 treats of the general technique of irradiating persons or organs. Chap. 4 deals with the practical therapeutics of irradiations: their use in rickets, in spasmophily and tetany, in disturbances of growth, in osteomalacia, osteomyelitis, fractures, pseudarthroses, laryngeal tuberculosis, cutaneous tuberculosis, fungous infections of the skin, acne, psoriasis, fistula, and many other diseases and pathological conditions. Therapeutic accidents are discussed. The bibliography comprises 10p.

15738. **AULAMO, RAUNO. Experimentelle Untersuchungen über die Einwirkung der Röntgenstrahlen auf das Kaninchenauge.** *Klin. Monatsbl. Augenheilk.* 86(4): 473-482. 1931.—Single doses of 2-10 E.D. soft x-rays were applied to the left eye in 8 rabbits, and of 1-13 E.D. hard rays to 11; the rest of the body was protected with lead. All eyes were examined with the corneal microscope, magnifying glass, and ophthalmoscope, before irradiation, and the day after, and twice a week, then weekly, for some time thereafter. Changes occurred in all those given soft rays and in 6 of those given hard rays. The conjunctiva contracted and, when the dose exceeded 5 E.D., the lids lost motility and the palpebral fissure was greatly narrowed. When 3 E.D. or more were given, epithelial and even parenchymal, clouding appeared in the central part of the cornea, the periphery remaining almost clear. In 2, iritis and iridocyclitis occurred. Cataract appeared in the course of months in 11 rabbits beginning with 2 E.D. soft, and 3 E.D. hard, rays. Intraocular tension did not increase; no changes in fundus or optic nerve were found (but they could be observed for only a short time because of corneal clouding); no dissolution of iritic pigment was observed. Sections showed the capsule unchanged even when the lens was entirely shriveled. Some thickening of the vessel walls of the ciliary body was observed but the author could not decide whether it was pathological.

15739. **BEHNKEN, HERMANN, und ROBERT JAEGER. Die Reproduzierbarkeit der Röntgendosiseinheit. (Bemerkung zu der Arbeit von A. Reisner und Th. C. Neeff: "Hauttoleranzdosis und Strahlenqualität" in Band 34, Heft 2, p. 313 dieser Zeitschrift.)** *Strahlentherapie* 36(4): 778-785. 3 fig. 1930.—The Reisner-Neeff publication [see Abstract 15761] offers no reason for mistrusting the present standard dosage unit; on the contrary, "r" is well defined and reproducible with an accuracy which exceeds the practical necessity.—*K. W. Buchwald.*

15740. **BODÓ, R., und G. ORBÁN. Das Hervorrufen von Herzflimmern durch hochfrequente Wechselströme.** *Pflüger's Arch. Ges. Physiol.* 227(3): 309-321. 1931.—The dampened harmonic oscillating currents of a frequency 500,000-1,000,000, common alternating current of a frequency of 50 periods, direct current and faradic current were administered to the heart of anesthetised dogs, one electrode being applied to the posterior surface of the right ventricle near the apex, the other at the anterior surface. The change in heart function was observed without instruments. The temp. of the heart musculature was determined immediately after the current was removed. Tesla current of a million periods of the intensity of 55 milli-amperes killed 4 of 8 dogs by heart fibrillation in less than 2 minutes. Alternating current of 50 periods was fatal at an intensity of 1.1 milli-amperes. Direct current results in immediate fibrillation at an intensity of 2 milli-amperes. After application of the 2 latter types of current there was an occasional recovery from fibrillation. The picture of the heart fibrillation produced by a current of high frequency is very similar to that effected by low frequency current. —*E. Lindemann.*

15743. **DUBOST, JEAN. D'une nouvelle methode d'investigation de la conductibilite du corps humain.** *Jour. Radiol. et Electrol.* 12(11): 536-545. 11 fig. 1928.—The technic used by the author in the study of the electrical resistance of the human body to alternating currents of low frequency is described. A current of audible frequency is given by an oscillatory lamp. The measurements are taken by means of Wheatstone's bridge to which is fitted an amplifier. This method gives correct data on impedance and angle of the human conductor and allows a fairly accurate graphic evaluation of "initial resistance."—*J. Dubost (transl.).*

15744. **EPIFANIO, GIUSEPPE. La radiologia e i nuovi orizzonti della biologia. Rapporti fra la biologia e la costituzione della materia. [Radiology and the new aspects of biology. Relation between biology and the constitution of matter.]** 58p. 5 fig. A. Trimarchi: Palermo, 1928. Pr., 12 L.—The ionization of the H atom, which is accomplished in the organism, and the phenomena of radioactivity in the surrounding atmosphere, are indices of the disintegration of the O, C, and N atoms. All these phenomena show the transformation of matter during biological activity; they are developed under the influence either of radiations or of excitation potentials of living matter which generate active currents.—*G. Tegoni (transl. by S. A. Thayer).*

15745. **EVANS, ARCHIBALD P. A method of controlling the destructive action of the Roentgen ray on living tissue.** *Arch. Phys. Therap., X-Ray, Radium* 10(4): 158-167. 7 fig. 1929.—The sensitiveness of the colloid systems to the x-rays is in the following order: neutral, electropositive and electronegative. The destructive effect of x-rays is due to their tendency to cause colloid systems of the organism to hydrate until they undergo lysis; it can be prevented by any method that will maintain the normal colloid state of the tissue in the radiated area. The tendency of x-rays to affect colloid systems may be neutralized by the utilization of a high oscillating electric circuit. The circuit described has proven to have neutralizing value.—*Author's conclusions.*

15746. **FISCHER, ALBERT. Mesothoriumbestrahlung von Gewebezellen in vitro.** *Strahlentherapie* 40(1): 54-96. 1931.—The author irradiated cultures of fibroblasts with mesothorium (equivalent to 5 and 40 mgm. of radium) according to the method of Laser and Halberstaetter and studied the resulting change of the area of the cultures. Numerous experiments are presented in detail. The following conclusions are drawn: The decrease in growth of the tissue cells caused by the radiation has a certain latent period. This period can not be solely explained by the fact that the cells in mitosis are radio-sensitive, for the decrease of growth is much greater than could be expected from the number of cell divisions during the radiation. The decrease in

growth is greater in cultures radiated at low temperatures than in controls radiated at body temp. The decrease of growth seems to depend on the gradual formation of injurious metabolic products in the radiated cells. The effect of these products on normal tissue cells can be demonstrated. The latent period depends only to a relatively small degree on the radiation intensity. All factors which influence the regenerative ability of the radiated tissue also increase the effect of the radiation. The effect of radiation on resting cells remains latent and only manifests itself as the cells start to proliferate. The radiation seems to attack the cells at the same mechanism upon which the proliferation catalysts act. The Bunsen-Roscoe law for photochemical reactions does not hold for the biological effect of the radium radiation.—*O. Glasser.*

15747. **FISCHER, ALBERT, und M. HORWITZ. Multiplikation der Wirkung kleinster Radiumdosen auf Gewebezellen in vitro.** *Strahlentherapie* 40(3): 465-469. 1931.—The authors radiated cultures of osteoblasts with small doses of mesothorium (equivalent to about .25 mgm. radium per hr.) and observed the inhibitory effect upon the growth of the fibroblasts. The experiments were made with the tissues at various temperatures (0-50° C.) before and after the radiation. The results show that the effect of small doses on these tissue cultures can remain latent; but by adding further small doses under various conditions it still can be shown to exist. The absolute radiation effect evidently does not depend on the rate of proliferation of the tissue cells. —*O. Glasser.*

15748. **HANCE, ROBERT T. The possible biological significance of the increased activity of x-rayed tyrosinase.** *Proc. Pennsylvania Acad. Sci.* 3: 90-92. 1929.

15749. **HAUSMANN, W., und W. E. PAULI. Über die Wirkung von Kathodenstrahlen auf Erythrocyten (Blutagarplatten).** *Strahlentherapie* 30(2): 350-358. 4 fig. 1928.—Blood agar plates were radiated with cathode rays by means of a specially constructed apparatus and the ring-shaped hemolysis produced by the radiation was studied. The erythrocytes in the center of this ring were not hemolyzed; they had become resistant against saponin. No reason for the formation of this peculiar effect can be given.—*O. Glasser.*

15750. **JACOBSEN, VICTOR C. The effects of high voltage cathode rays on the germinal epithelium of the rat.** *Arch. Pathol.* 9(5): 967-983. 8 fig. 1930.—The effect of cathode rays from a Coolidge cathode ray tube, operated at voltages of 200,000-250,000 volts at a current of 1 m.a., upon the germinal epithelium of the adult ♂ white rat was studied. Exposure times varied from ½ sec. to 30 sec. Definite lesions were produced in the seminiferous tubules in a zone about .6 mm. in depth. Degenerative and necrotic changes were observed in this zone similar to those caused by x-rays. The germinal epithelium is much more sensitive to this radiation than the tela subcutanea. It is concluded that the biological effects of x-rays are due to the electrons or cathode rays set free in the tissues.—*O. Glasser.*

15751. **KEMP, TAGE, and JENS JUUL. Influence of various agents (x-rays, radium, heat, ether) upon mitosis in tissue cultures.** *Acta Path. et Microbiol. Scand.* 7(3): 279-308. 3 pl. 1930.—Tissue cultures of fibroblasts from chick embryos were exposed to Ra and x-rays in various doses, ether vapor, and heating to 50° for various periods. The cultures were fixed at different times within the first 24 hrs. after the treatment, and the mitoses were examined. The radiation treatment was followed by characteristic variations in the number of mitoses: an early initial fall—after large doses, to zero—and then a rise, up to normal when the dose was small. After 3-6 hrs. there is again a fall of the mitosis count. Examinations within the first hr. after the irradiation show that most of the cells that have entered mitosis prior to the irradiation complete the division, whereas no new mitoses are formed in this period. After ether and heat treatment no such variations are found in the number of mitoses. After ether treatment, the findings were not constant. After heating, the mitosis count stayed fairly constant in the first hrs. after the treatment; then it went down slowly. The morphological changes observed in the individual mitoses are essentially alike after exposure to radiation, ether and heat. They are particularly distinct in the first period after the treatment, more moderate in the secondary mitosis wave. These changes appear as: pycnotic mitoses; shrinkage and clumping—perhaps, fragmentation also—of the chromosomes; and disturbances of the chromosome migrations, particularly in the anaphase. There is a complete absence of certain mitotic changes that are characteristic of the anaplasia of cancer tissue, such as multipolar mitoses, very large mitoses, and marked variations of the chromosome count.—*Authors' summary.*

15752. **KRUPSKI, A. I., und M. F. EISENBERG. Über den Einfluss schwacher Röntgenbestrahlung der Ovarien auf die Nachkommenschaft bei weissen Mäusen.** *Strahlentherapie* 30(3): 527-543. 1 fig. 1928.—On 40 white mice doses of 12, 24 and 36% erythema units were given to the ovarian tissues without castration. Three generations of offspring were observed, being normal. Six children of x-ray technicians were observed to be normal. The question of what intensity of radiation is dangerous is left open.—*H. Kahler.*

15753. **KÜSTNER, HANS. Die Dosierung der Buckyschen Grenzstrahlen mit dem Eichstandgerät. II.** *Strahlentherapie* 30(2): 334-342. 6 fig. 1928.—For very soft rays (4 to 12 kv.) the absorption of the Lindemann glass must be allowed for in estimating the intensity of radiation given off by a tube at a given power input. Both glass and air by selective absorption of the softer rays act as filters. Bucky rays must have intensity and wave length determined at the same focal distance as used in practice.—*H. Kahler.*

15754. **LACASSAGNE, A. Comparaison entre l'effet produit dans le testicule par les rayons corpusculaires β et par les rayons ondulatoires X.** *Arch. Anat. Microsc.* 25: 251-256. 1929.—A small cylinder of uranium X was introduced into the testicles of dogs and rams. Successive zones were produced of (1) total local necrosis; (2) inflammation; (3) sterilization; (4) temporary interruption of the generation of the seminal cords. The zones of inflammation and sterilization were similar to those produced by x-rays but β rays of uranium X produce dangerous local necrosis.—*H. Kahler.*

15755. **LANGENDORFF, H., und M. LANGENDORFF. Strahlenbiologische Untersuchungen an befruchteten Seeigeleiern.** *Strahlentherapie* 42(4): 793-799. 1931.—Studies were carried out on 9 series of sea urchin eggs (*Psammechinus miliaris*). 3 series were x-rayed in each stage (i.e., 1st, 2nd, and 3rd segmentation divisions). Those in the 1st stage were given 200 r 35 min. after fertilization; those in the 2nd and 3rd, 200 r 55-120 min. after fertilization. The 1st cleavage stage was given fractionated doses: 200 r in 5, 35, and 55 min. respectively, or 100 r. given twice at 5 and 35, 35 and 55, or 5 and 55 min. (5 and 55 min. being periods of maximum, 35 of minimal sensitivity). The results substantiated earlier work. In the 2nd and 3rd segmentation divisions the cell was least sensitive during the metaphase. The stage of mitosis was also determinant for the action of simple fractionated doses, about the same effect being obtained with the fractionated doses applied at the 2 maxima as when the total dose was applied at the 2nd maximum.

15756. **McKINLEY, G. M. Some biological effects of high frequency electrostatic fields.** *Proc. Pennsylvania Acad. Sci.* 4: 43-46. 1930.—A brief review of the author's recent experimentation.

15757. **MOPPETT, WARNFORD. The differential action of x-rays on tissue, growth and vitality. II. The biological reaction to x-radiation in relation to a phenomenon termed antagonism. III. The biological reaction to x-radiation in relation to the area of tissue irradiated. IV. The biological reaction to x-radiation in relation to time.** *Proc. Roy. Soc.* [*London*] B 107(751): 293-312. 1 pl., 6 fig. 1930.—II. The allantoic membrane

of the embryo chick, irradiated with homogeneous x-rays obtained by crystal diffraction, shows a reaction consisting of hypertrophy or atrophy which is associated with a definite frequency band. Any frequency outside this band tends to diminish or prevent the reaction. A prior dose of mixed radiation prevents a reaction due to homogeneous radiation. In this instance increasing doses of both radiations may be balanced against each other; a curve resembling a hyperbola was thus obtained. —III. The threshold dose for a reaction of the allantoic membrane to homogeneous x-radiation varies inversely as the square of the area irradiated for small areas. The reaction represents a summation of stimuli from adjacent parts which may not show any visible change. When 2 discrete areas are irradiated, a fused reaction may be obtained in the central non-irradiated part and the threshold dose varies as the square of the distance between parts up to 6.5 mm. Similar laws appear to hold when the skin of the rat is exposed to unfiltered soft mixed radiation and the possible rôle of the ionised atom is discussed.—IV. The allantoic membrane was exposed to homogeneous radiation for various periods of time at various intensities and the threshold dose was plotted against time. The curve showed a minimum value at 1½ hrs. and 2 upward branches representing an increase in threshold dose when T is small and a "repair factor" when T is large. The skin of the mouse exposed to soft mixed radiation shows a similar curve except that repair was more rapid in the highly differentiated tissue. Approximate equation $TD=K/T+(a+\beta)T$ where a represents the return of the ionised atom to a normal state and β a biological constant of repair.—*W. Moppett.*

15758. **OLIVIERI, FRANCESCO. Ricerche intorno all'azione dei raggi Röntgen sulla segmentazione dell'uovo e sui processi morfogenetici elementari nel Bufo vulgaris. [The action of x-rays on the segmentation of the ovum and on elementary morphogenetic processes in B. vulgaris.]** *Riv. Radiol. e Fis. Med.* 1(5): 5-30. Portrait 10 fig. 1929.—A large series of fertilized eggs of *Bufo vulgaris*, some of which were given x-rays (various doses) during segmentation, gastrulation, and the neural groove stage, were studied. Irradiation during segmentation seemed to interfere with harmonious development during that stage; during gastrulation, the injurious effects seemed to be limited to the entero-vitelline portion, and to induce a resistance or susceptibility to irradiation in certain zones and a stimulation in others; during the neural groove stage, x-rays did not interfere with morphogenesis.

15759. **QUIMBY, EDITH H., and FRED W. STEWART. Comparison of various sources of interstitial radiation.** *Radiology* 17(3): 449-470. 14 fig. 1931.—The authors have made experimental investigations of the distribution of radiation intensity around radioactive sources of various types, used interstitially. This was studied by means of 2 reactions, the bleaching of butter and the production of necrosis in the dorsal muscles of rabbits. The sources of radiation were tubes of radium sulphate and of radon, of different strengths, lengths, and filtrations. Curves and tables are given for the relative intensities of radiation at different distances from a standard radon "seed" 4 mm. long, filter 0.3 mm. gold. Factors are given by means of which similar data can be calculated for any interstitial source of radiation ordinarily used in therapy. These data are correlated with data previously obtained regarding the production of erythema on human skin, and on this basis it is assumed that such experimental data can be used as a satisfactory first approximation to determining tissue dosage. For any given source, the effect produced at any given point is proportional to the dose in millicurie-, or milligram-hours.—Extensive dosage tables are given for various types of permanent and removable radium and radon implants.—*E. H. Quimby.*

15760. **REGELSBERGER, H. Grundsätzliches über Polarisationsmessungen an der menschlichen Haut. III.** *Zeitschr. Ges. Exp. Med.* 76(5/6): 635-652. 1931.—Variations in the direct current passing between 2 electrodes applied to different parts of the body were observed. A daily rhythmic variation occurred for all parts of the body. The curve of current plotted against time of day showed maxima at 2 P. M. and 7:30 P. M. with minima at 10 A. M. and 5 P. M. Such variations were more marked by taking readings at ½-1 hr. intervals than with shorter intervals between readings. A continuous current showed none of the rhythmic variations. The effect of continued pressure on the electrodes is discussed and oscillograms of electrodes using different salt solutions are given.—*A. Hemingway.*

15761. **REISNER, A., und TH. C. NEEFF. Hauttoleranzdosis und Strahlenqualität.** *Strahlentherapie* 34(2): 313-339. 1 col. pl., 15 fig. 1929.—The dependence of the skin tolerance dose on the quality (i.e., wave length) of the x-ray radiation used (measured in half-value thickness of Cu and r units) has been investigated by means of a series of observations on skin erythema on the skin of the thigh, in women. The following relations between wave-length and skin reaction have been found: —(1) The skin tolerance dose increases with the wave length for radiation varying from 0.3 mm. to 0.2 mm. of Cu half value layer. After this, it decreases rapidly with increasing wave length. (2) The use of doses less than the tolerance dose in such an investigation may lead to false conclusions, because in this case differences between the reactions vanish. Doses close to the tolerance limit show the differences clearly. (3) This explains the differences in results obtained by earlier observers, and should bring about agreement regarding the question of the dependence of skin tolerance dose on radiation quality. (4) The physical and biological conditions of the experiments are fully discussed, and necessary precautions described. All dosage data have been determined on the basis of the standardization according to Kuestner. [See also abstract 15739.] —*Authors' summary (transl. by E. H. Quimby).*

15762. **RUSS, S., SAMSON WRIGHT, H. A. BULMAN, and L. H. CLARK. The physiological and cytological effects of penetrating x-rays upon the cat and rabbit.** *Proc. Roy. Soc. Med.* 23(12): 1671-1688. 6 fig. 1930.—A large number of cats and rabbits were placed in wooden boxes, and irradiated from above with heavy doses of x-rays of frequencies of 150 and 230 kv. applied (1) to the thorax only, (2) to the abdomen only, (3) to the entire body with the exception of the kidneys and adrenals, which were protected by a lead belt, and (4) to the long bones only. In general the dosage used was such as would prove lethal. The physiological symptoms leading to death are described in both test animals. Detailed examinations of all organs are reported, with the changes found in the alimentary canal, small and large intestines, stomach, liver, kidney, respiratory tract, spleen, blood. The principal damage occurred in the blood, intestinal tract, kidney, liver and bone marrow. Primary infection was not necessarily present in the x-ray lesions, but if secondary infection occurred, it progressed rapidly. X-ray sickness, compared with histamine poisoning, showed marked differences; x-ray sickness is probably not due to histamine released in the organism by the action of the rays. The blood changes which occurred after very heavy irradiation consisted mainly in loss of lymphocytes and polymorpho-nuclear leucocytes; the effect on red cells and platelets was almost negligible, even when the animal was practically moribund. Under certain circumstances, however, an x-ray anemia could be produced. Liver feeding was of no use. The action of the rays seems to be indirect, in that the metabolism of the cell is first disturbed.—*E. H. Quimby.*

15763. **SCHLUNDT, HERMAN, and G. FAILLA. The detection and estimation of radium in living persons. III. The normal elimination of radium.** *Amer. Jour. Roentgenol.* 26(2): 265-271. 1931.—Two girls who had contracted Ra poisoning during their employment as dial painters in 1918 were still radioactive after a lapse of 12 yrs. during which time neither had been exposed to Ra. The rate of elimination of Ra by these subjects

under normal diet and living conditions was determined in the excreta collected over a period of hospitalization for a week. The total Ra distributed over the bony skeleton was also determined quantitatively. The elimination by subject A, bearing 24 μg. (2.4×10^{-6} gm.) radium averaged 1,161 $\mu\mu$g. (1.16×10^{-12} gm.) daily, or a coefficient of daily elimination of 5×10^{-5} (0.005%). Subject B, carrying a total of 14 μg. radium, eliminated 363 μg. daily, or only 0.0026%. Fully 90% of the Ra eliminated was found in the feces. Several considerations are advanced for the observed difference in the rates of elimination in the 2 subjects, and some of the important factors involved in the problem of Ra elimination by living persons are discussed.—*H. Schlundt.*

15764. **SCHUGT, P. Experimentelle Untersuchungen über Schädigung der Nachkommen durch Röntgenstrahlen.** *Strahlentherapie* 28(3): 546-567. 2 fig. 1928.—Studies on mice are reported.

15765. **STRELIN, G. S. Röntgenologische Untersuchungen an Hydren. II. Die histologischen Veränderungen im Körperbau von Pelmatohydra oligactis unter der Wirkung der Röntgenstrahlen und ihre Bedeutung für die Regeneration und Vermehrung.** *Zeitschr. Wiss. Biol. Abt. D. Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 115(1/2): 27-51. 15 fig. 1929.—The author studied the histological changes in fixed and stained serial sections of hydra used by Zawarzin in his experiments, and also performed new experiments on the action of rays on undifferentiated interstitial elements between ectoderm and entoderm of hydra, to determine histological changes at earlier stages under various doses of rays. He concluded that the law of Bergonié and Tribandeau is fully confirmed. The action of x-rays is evident without an intervening latent period. Cells of embryonic nature, i.e., interstitial cells, are most sensitive to x-rays, especially at prophase. A strong dose leads to the disappearance of interstitial cells, which in turn leads to degeneration; but if any interstitial elements survive, they will be later regenerated completely or even excessively. The acceleration of regeneration is explained by the regenerative reproduction of interstitial elements. —*P. M. Suski.*

15766. **STROHL, ANDRÉ, et HENRI DESGREZ. Etudes des ondes faradiques emises à travers le corps humain.** *Jour. Radiol. et Electrol.* 13(8): 417-432. 1929. —In studying the Faradic currents (on opening) with the aid of "l'égersimètre," the mean voltages of the current in the different parts of the cycle were studied. Placing a patient in the secondary circuit caused changes in the wave form, due to the polarization capacity of the tissues; in fact, electric oscillations were produced and studied.—*A. Strohl (transl. by J. F. McClendon).*

15767. **WEATHERWAX, J. L., (with foreword by HENRY K. PANCOAST). Physics of radiology.** 240p. 126 fig. Paul B. Hoeber, Inc.: New York, 1931. Price $5.

15768. **WRIGHT, SAMSON, and H. A. BULMAN. Selective action of x-rays on the blood cells of the cat.** *Lancet* 217(5527): 217-219. 1929.—The entire body was irradiated at 57 cm. distance for varying periods, spark gap 10 cm. 1 mm. of Al being the filter. For a duration of 75 min. death results within 5-12 days. If the exposure is less than 60 min. all survive. For doses less than the lethal dose the lymphocytes are decreased early and markedly, the polymorphonuclear leucocytes decrease more slowly. The red cells decrease slowly and the platelets appear to change in a parallel direction both gradually recovering. In fatal cases haemolysis occurs.—*H. Kahler.*

15769. **WYNEN, WALTER. Die Radiosensibilität des Knochens in ihrer Bedeutung für die Röntgenbestrahlung der Gelenktuberkulose.** *Münchener Med. Wochenschr.* 76(6): 244-246. 1 fig. 1929.—Bones are much more resistant to x-rays than most other body tissues. Regaud believes the Ca gives off secondary radiations which destroy the delicate vascular walls within the bone lamella. In order to test this idea, root tips of *Vicia faba equina* were placed in holes drilled in bone and another set were similarly placed in muscle. Both received the same radiation 180 k. v. 4 ma. 30 cm. T.S.D. and 150 r-units. After 8 days the ones radiated in bone were further ahead than those in muscle, showing that the bone filtered out a great deal of the radiation. Practical considerations have led to the use of hard radiations in tuberculosis. Small doses are quicker and more satisfactory than massive doses. The hard radiations penetrate in sufficient amounts to the required depth while the softer radiations are absorbed chiefly in the superficial layers. The author does not maintain that radiation with Al filtration is less effective, but that the treatment is dangerous.—*K. W. Buchwald.*

15770. **ZAWARZIN, A. A. Röntgenologische Untersuchungen an Hydren. I. Die Wirkung der Röntgenstrahlen auf die Vermehrung und Regeneration bei Pelmatohydra oligactis.** *Zeitschr. Wiss. Biol. Abt. D. Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 115(1/2): 1-26. 9 fig. 1929.—In a series of experiments during 2 summers, the author found that rays accelerate and stimulate, or retard asexual reproduction and regeneration of hydra according to the doses given and the time elapsed since irradiation. The stimulating action appears directly after exposure, but the depressant action after a certain lapse of time, which is inversely proportional to doses given. There exists no latent period of action of x-rays. With the test conditions (65 K.V., 2 M.A., 16 cm. distance, no filter, superficial dose 79 r. per min., 300 r. to a HED), 6 min. exposure gave the highest general stimulating effects. Aside from the primary stimulation by x-rays, there is a secondary stimulation which occurs only with stronger doses. An operation contributes to a greater resistance of hydra to the injurious effects of x-rays. Autumn hydra are more resistant than summer hydra.—*P. M. Suski.*

15771. **BARMORE, MARK, and JAMES MURRAY LUCK. The rôle of phosphate in biological oxidations.** *Jour. Gen. Physiol.* 15(1): 97-105. 1931.—A qualitative and quantitative study of the catalytic effect of phosphates on the oxidation of glyceric aldehyde by dyes (methylene blue, 1-naphthol, 2-sulphonate indophenol, and phenol indophenol). It was concluded that the $PO_4^{\equiv}$ ion is a more active catalytic agent than $HPO_4^{=}$ or HPO_4^{-}.—*M. Barmore.*

15772. **BARRON, E. S. GUZMAN, and L. A. HOFFMANN. The catalytic effect of dyes on the oxygen consumption of living cells.** *Jour. Gen. Physiol.* 13(4): 483-494. 1930.—A study of the effect of reversibly oxidized and reduced dyes on the O consumption of sea-urchin and starfish eggs. The catalytic power of the dyes on the O consumption of these eggs is conditioned by 2 factors. Dyes whose E'_o is towards the positive side of the aerobic reduction potential of the eggs have a maximum catalytic effect. This catalytic power decreases as the E'_o becomes more negative than the reduction potential of the cell and becomes nil beyond certain limits. When a dye cannot penetrate into the cell its effect is greatly diminished, as in this case only those oxidative processes taking place at the outer sur-

face of the cell can be activated. The speed of this activation is correlated to (1) the speed at which the dye is reduced by the cell, and (2) the speed at which the leuco-dye is oxidized by atmospheric O.—*E. S. G. Barron.*

15775. **PALIT, C. C., and N. R. DHAR. Slow and induced oxidation of glycogen, lecithin, cholesterol, formate, oleate, stearate, and some food materials.** *Jour. Phys. Chem.* 34(4): 711-723. 1930.—An aqueous suspension of glycogen was oxidized by air at 25° C. in the presence of NaOH, $NaHCO_3$, and different metallic hydroxides. This oxidation is retarded by fats and nitrogenous substances. The induced oxidation of potassium stearate and oleate by air is retarded by carbohydrate, and to a greater extent by carbohydrate and urea, but the combustion is more complete. In neutral solutions with cerous hydroxide as inductor the order in which oxidation takes place is as follows: egg white>egg yellow>starch>glucose>butter; the same order obtained by Voit for actual feeding experiments. The substances are oxidized chiefly to CO_2 and not to any intermediate product. The authors think these results of importance because the oxidations are of the same type as those taking place in the animal body.—*T. O. Stevens.*

15776. **VELLINGER, EDMOND. Notes sur le potentiel d'oxydation-réduction de matières colorantes usuelles utilisables comme tampons de rH.** *Arch. Phys. Biol.* 7(2): 113-118. 1 fig. 1929.—Approximate potential measurements on various dyes.—*F. Bernheim.*

15777. **[VLADIMIROV, G. E., M. ĬA. GALVĬALO, and K. A. MAKAROVA.]** ВЛАДИМИРОВ, Г. Е., М. Я. ГАЛВЯЛО и К. А. МАКАРОВА. Глютатион, методы его получения, его свойства, термостабильная окислительно-восстановительная система. **[Glutathion; methods of obtaining it; its properties; thermostable oxidizing-reducing system.]** [German summary.] Русский Физиологический Журнал имени И. М. Сеченова (*Russ. Jour. Physiol.*) 13(4/5): 499-524. 1930.—Glutathion obtained by Hopkins' method was somewhat different in quantitative chemical composition from that obtained by Johnson and Voegtlin's method. By these methods glutathion was isolated even from 10 kgm. of yeast, brewer's yeast being unsatisfactory material. When cystein and glutathion were oxidized with iodine, the reaction proceeded beyond the disulphide form ($2RSH+I_2=RS-SR+2HI$), and was inhibited by acid and KI. Exact iodometric titration of cystein and glutathion (starch as indicator) was possible only under standard conditions in the presence of a known and sufficient amount of acid and KI. Repeated treatment of muscle preparation with the disulphide form of glutathion removed most of the H from the SH group of the muscle preparation. The S of the free SH groups of a muscle preparation represented a significant part of the whole S of the muscle.—*S. A. Corson.*

ANIMAL PHYSIOLOGY

BIOCHEMICAL, BIOPHYSICAL AND PHYSIOLOGICAL METHODS AND APPARATUS

C. H. FISKE, *Editor,* Biochemical and Biophysical

S. E. POND, *Editor,* Physiological

(See also in this issue Entries 15140, 15142, 15148, 15149, 15150, 15528, 15571, 15652, 15657, 15658, 15678, 15745, 15763, 15800, 15808, 15825, 15826, 15843, 15844, 15849, 15893, 15902, 15997, 15999, 16058, 16150, 16157, 16179, 16264, 16294, 16765, 16875, 17492)

BIOCHEMICAL AND BIOPHYSICAL

15778. **BRAVO, GIUSEPPE ANTONIO. La concentrazione degli ioni idrogeno. Il significato del simbolo pH e la sua misura.** 203p. 62 fig. Tipografia Sociale Torinese: Turin, 1929. Price 22 L.—This is essentially a practical treatise dealing with the methods of pH determination in analytical chemistry and also in industry (manufacture of paper, inks, dyes, gums, tannery products, sugar, fermentations, etc.). The author also considers the applications of the same methods for the evaluation of the constants of dissociation and hydrolysis as well as applications in biological chemistry. In addition to the 2 principal methods, the electrometric and the colorimetric, descriptions are given of those based on spectrophotometry, catalysis, electrical conductivity, viscosity and surface tension.—*G. Tegoni (transl. by B. Cohen).*

15779. **GANASSINI, DOMENICO. Modificatione ad un metodo di dosaggio dell'acido urico nelle orine. [A modified method for determination of uric acid in urine.]** *Arch. Ist. Biochim. Ital.* 2(4): 505-508. 1930.—For the Salkowski Ludwig reagent a solution of $ZnSO_4$ is substituted, to which a slight excess of Na_2CO_2 is subsequently added. Uric acid is precipitated as basic Zn urate, is then dissolved with HCl, and the Zn precipitated with Na phosphate. The uric acid is determined as Na urate with a $N/10$ I solution with indigo carmin as indicator.—*M. Comel.*

15780. **LEVENE, P. A., and ERIK JORPES. A method of separation of ribopolynucleotides from thymonucleic acid and on the conditions for a quantitative separation of the purine bases from the ribopolynucleotides.** *Jour. Biol. Chem.* 86(1): 389-401. 3 fig. 1930.—Ribonucleic acid was pptd. readily from a 10% aqueous soln. by excess glacial acetic acid, while the thymonucleic acid remained dissolved. To isolate purine bases from ribonucleic acid, Levene's method for thymonucleic acid was modified in its details: Suspend 5 gm. of the acid in 150 cc. dry methanol and pass in HCl gas for 1½ hrs. with continuous agitation. After initial solution of the acid, the hydrochlorides of the bases gradually separate. Let stand overnight in the cold. Dissolve the hydrochlorides in excess alkali and neutralize with acetic acid. Guanine settles out at once; adenine remains in soln. For complete sepn., redissolve the guanine in alk. and reppt. with acetic acid. Precipitate adenine from the combined filtrates as the picrate.—Theoretical yields of base were obtained by application of the above to pure guanine-HCl, to a known mixture of the 2 bases, and to yeast nucleic acid. The pancreas nucleic acid purified as above differed from the yeast nucleic acid in the higher content of ribose and purine bases, and particularly in the greater proportion of guanine to adenine, in the former. On partial hydrolysis, adenosine and guanosine were prepared from this acid.—*W. A. Peabody.*

15781. **OSATO, SHUNGO, and MUTSUO HEKI. On the micro determination of lipids in tissues.** *Jour. Biol. Chem.* 87(3): 541-557. 1 fig. 1930.—Practically all fatty substance is removed when tissue is reduced to a homogeneous paste by freezing, moistened and ground in a mortar repeatedly, and mixed with a suitable solvent

(alcohol-ether mixture). In this extract total fatty acid, lecithin, and cholesterol are determined. For the micro estimation of total fatty acid, the Bang-Bloor oxidative method is preferred. A slight improvement is given for the estimation of free and combined cholesterol, to facilitate the precipitation of cholesterol digitonide and to simplify the manipulation of extraction.—*S. Osato.*

15782. **PFIFFNER, J. J., and VICTOR C. MYERS. On the colorimetric estimation of guanidine bases in blood.** *Jour. Biol. Chem.* 87(2): 345-355. 1930.—A study was made of the colorimetric reaction of certain guanidine bases with alkaline oxidized nitroprusside and ferricyanide. Weber's method (1927) for the estimation of guanidine bases in blood was modified to exclude interference by creatine, and the modified method was applied to a few normal and hypertensive blood samples.—*J. J. Pfiffner.*

15783. **PINELLI, LUIGI, e ATTILIO CORBIA. Sui metodi da preferirsi per la determinazione clinica della glicemia.** [Clinical methods for determining blood sugar.] *Biochim. e Terapia Sperim.* 18(1): 19-33. 1931.—The methods of Folin and Wu, of Shaffer and Hartmann, of Hagedorn and Jensen, of Jonescu and Mathiu, and of Bertrand and Silvestri were compared. Those based upon the reduction of ferricyanide regularly gave higher values than those based upon reduction of cupric salts.—*M. Comel.*

15784. **STROHECKER, R. Die Bestimmung des Stickstoffsubstanzgehaltes der Milch mit Hilfe eines Leitfähigkeitsabfalls.** *Zeitschr. Untersuch. Lebensmittel* 61(1): 69-80. 1931.—The author suggests a method for determining the nitrogenous material in milk based on the decrease in conductivity of a dilute HCl solution when mixed with a definite quantity of milk. The method is said to give results in good agreement with the Kjeldahl method and is applicable to ordinary or evaporated milk without correction; in sweetened condensed milk a correction factor is necessary. Benzoates and borate preservatives and sodium carbonate interfere with the determination; not so H_2O_2 and formalin.—*R. W. Titus.*

15785. **TAILLANDIER, M. Études et techniques de précipitation des constituants des liquides biologiques en vue de leur dosage opacimétrique par spectrophotométrie et photométrie.** 255p. 41 fig. Norbert Maloine: Paris, 1931.—The author reports the results of a study of the theory and practice of the use of photometric and nephelometric methods in analytical chemical procedures with the particular purpose of establishing satisfactory technique for the determination of constituents of biological fluids such as blood, serum, plasma, urine, cerebro-spinal fluid, etc., 85 p. of historical and theoretical discussion are included. Results previously reported in 1927-28 and others obtained since then are combined in the description of technique for the determination of chlorides, uric acid, phosphates, acetone, reducing sugars, cholesterol, calcium and urea. The methods are suitable for clinical use. In general the percentage errors are greater than in the corresponding gravimetric methods but equal to or less than those in the corresponding volumetric methods. Up to the present time the results with the cholesterol technique are not so constant as those obtained by the colorimetric method. The basic instrument used throughout is the photometer of Vernes and Bricq, especially constructed for absorption measurements with small quantities of liquid. Observations are described made with the photometer of Vernes, Bricq and Yvon, the spectrophotometer of Fery and the apparatus of Baudouin and Bénard. A number of other instruments are discussed. The preliminary discussion suggests certain theoretical advantages of these methods as compared with a number of familiar nephelometric procedures.—*R. L. Nugent.*

15786. **TAPERNOUX, A., et FÉRY. Sur le dosage colorimétrique de l'acide lactique; applications au dosage de l'acide lactique des caséines industrielles.** *Compt. Rend. Soc. Biol.* 100(14): 1213-1214. 1929.—1 gm. of casein is macerated with 20 cc. distilled water at 40° for about 15 min., then heated to near boiling, filtered, and 1 cc. of the filtrate treated with 10 cc. pure H_2SO_4 and kept in a boiling water bath 2 min. This is cooled, and to it are added 10 drops of alcoholic solution of guaiacol (1-20). The color is then compared with a scale prepared from solutions of known lactic acid content.

15787. **TASHIRO, SHIRO, and ESTHER BOGEN TIETZ. A simple test for levulose (ketose?) in glucides.** *Jour. Biol. Chem.* 87(2): 307-310. 1930.—"In a small test-tube (preferably 1 cm. in diameter) place 1 cc. of 0.1 per cent fresh aqueous solution of ordinary ox bile salts. Add 1 cc. conc. H_2SO_4, shake immediately, and quickly add to the mixture a drop of solution to be tested. An immediate production (in about 15 sec.) of pink or purple color on the top of the solution indicates the probable presence of levulose, free or in combination." The concentration of levulose must be $M/600$ or higher. All sugars give the test if the concentration is high enough.

15788. **VERAIN, M. Sur un nouveau potentiomètre.** *Compt. Rend. Soc. Biol.* 106(10): 821-822. 1 fig. 1931.—A new modification of the potentiometer with resistance boxes is described. The resistances are introduced directly into the circuit, thus eliminating errors due to faulty connections. A direct reading in millivolts can be made on an attached rheostat. Of 600 determinations, 550 came within 0.04 of the true pH and the greatest divergence was 0.12. All parts of this apparatus are easily accessible for cleaning.—*E. Weiner.*

15789. **WEISE, W., und C. TROPP. Untersuchungen über die Jaffesche Pikrinsäurereaktion.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 178(1/3): 125-138. 1928.—The Jaffe reaction for creatinine (the red coloration of an alkaline picric acid solution) is a special case of a general reaction for active methylene and methine groups. After tabulating the results for a large number of compounds, the authors list the activating groups in the following order with nitro as the strongest: nitro, diazo, carbonyl, cyano, vinylene, carbaminyl, carbethoxy. Simple aldehydes and ketones give a positive reaction. Although malonamide gives a positive reaction, most acid amides give the characteristic color only when the CH_2 group is combined with an aromatic group (as phenylacetamide) or is in cyclic combination (as hydantoins and diketopiperazines). Method: 10 cc. of a saturated aqueous solution of picric acid; 5 cc. of 10% NaOH. Dilute mixture to a volume of 25 cc. Use 5 cc. of this reagent and 20-50 mg. of the substance to be tested. The test is positive if a definite red color is obtained in 3 minutes. With material insoluble in H_2O the test is carried out as above; after 3 minutes an equal volume of alcohol is added. If no red color develops after another 3 minutes, the test may be considered definitely negative.—*A. Renfrew.*

15790. **WILEY, FRANK H., and HOWARD B. LEWIS. The action of nitrous acid on casein. 2.** *Jour. Biol. Chem.* 86(2): 511-528. 1930.—Casein deaminized by $NaNO_2$ and acetic acid at various temperatures was prepared, and the deaminized casein analyzed by some of the newer methods of protein analysis. The study gave evidence of the inaccuracy of the Van Slyke method for the determination of characteristic groups of the protein molecule as applied to deaminized casein. The arginine content of deaminized casein as determined by the Van Slyke procedure was slightly lower than that of casein. This was not substantiated by the results of the Vickery-Leavenworth method of analysis, by which practically the same amounts of arginine could be isolated as the flavianate from casein and deaminized casein. The Vickery-Leavenworth method indicated a destruction of more than half of the histidine present in casein in the reactions involved in deamination. The Van Slyke procedure indicated a degree of destruction of lysine varying with the temp. of deamination, while by the Vickery-Leavenworth method no lysine could be isolated from the hydrolysate of casein deaminized at 20°. The tryptophane content of casein, as determined by the colori-

metric method of Folin and Ciocalteu, was not altered by the reactions of deamination. Tyrosine, as determined by the colorimetric methods of Folin and his associates, appeared to be partially destroyed in deamination. Evidence is presented that this decrease is probably due to the formation of derivatives of tyrosine during deamination, which had less chromogenic value in the color reactions used in the determination of tyrosine than tyrosine itself.—*Authors' summary.*

15791. **WIND, F., und K. v. OETTINGEN. Milchsäurebestimmung in den Uterus- und Nabelgefässen.** *Biochem. Zeitschr.* 197(1/3): 170-174. 1 fig. 1928.—A method is described for determining lactic acid in 1 cc. of blood. Analysis of the blood entering and leaving the system embryo + uterus + placenta shows that this system does not add lactic acid to the blood.—*P. A. Katzman.*

15792. **YONEYAMA, YAHEI. Über Luminescenzanalyse des Harnes.** *Zeitschr. Ges. Exp. Med.* 76(5/6): 680-688. 1931.—Various constituents of the urine, particularly: urochrome, uro-erythrin, urorosein, urorubin, urobilin, and coproporphyrine with its chromogens, especially urobilinogen, when subjected to ultraviolet illumination in the dark, gave characteristic colors.

VITAMINES

15793. **ALLEMAN, IRENE LILLIAN. Quantitative comparative studies of the solubilities of Vitamins B and G in acidified alcohol, with suggestions regarding the methods of determining these vitamins.** 39p. 11 fig. Thesis: Columbia University, New York City, 1930.—Both Vitamins B and G appear to be equally soluble (extractable) in 80% alcohol alone and alcohol of that strength made $M/10$ with gallic, benzoic, or hydrochloric acid, about $\frac{1}{3}$ of the vitamins originally in the milk powder remaining in the residues, under the conditions of extraction employed. The extracts appear to contain all the Vitamin B not left in the residues, but less of Vitamin G than would be expected from the amount remaining in the residues, that extract prepared with alcohol acidified with gallic acid being the most potent source of Vitamin G. Two changes of method are suggested for the estimation of these vitamins: (1) reducing the length of experimental period to avoid vitiation of results by unrecognized factors; (2) beginning experimental period at point of minimum weight of experimental animal.—*I. L. Alleman.*

15794. **ANGUS, T. C., F. A. ASKEW, R. B. BOURDILLON, H. M. BRUCE, R. K. CALLOW, C. FISCHMANN, J. ST. L. PHILPOT, and T. A. WEBSTER. A crystalline antirachitic substance.** *Proc. Roy. Soc.* [*London*] *B* 108(757): 340-359. 6 fig. 1931.—A crystalline antirachitic substance has been obtained by distillation of irradiated ergosterol in a high vacuum. Several grams of this substance have now been produced, as compared with the few milligrams described earlier. Attempts to detect a possible contaminant of high antirachitic activity failed, and it is believed that the observed activity is an inherent property of the substance. The name "calciferol" is provisionally suggested, pending further elucidation of the structure of this substance. It shows a high antirachitic activity of 20,000 M.R.C. units per mgm., a melting point of 123-125° C., and a high dextrorotation $[\alpha]^{29}_{5461}+260°$. It appears to contain an alcoholic hydroxyl group, and to be an isomeride of ergosterol. It shows unexpected stability, being almost unchanged after keeping for 6 weeks in vacuo, or even in dry air at room temperature. Its relation to "vitamin D" is discussed, with the conclusion that there are probably not less than 2 compounds each possessing intense antirachitic activity. It is uncertain whether calciferol is normally present in irradiated ergosterol, or is produced only by the subsequent action of heat.—*Authors' summary.*

15795. **[BOVSHIK, G. A.]** БОВШИК, Г. А. Сравнительное изучение пшеничного хлеба, приготовленного на пивных и хлебопекарных дрожжах, в отношении содержания витаминов В. **[Comparative study of vitamin B content in wheat bread baked with brewers' and bakers' yeast.]** [French summary.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 237-242. 1930.—Wheat bread baked with 12% of baker's yeast was deficient in vitamin B, the pigeons fed on this bread being unable to maintain their original weight. Wheat bread baked with 6% of brewer's yeast had sufficient vitamin B.—*S. A. Corson.*

15796. **BRACEWELL, MARY F., E. HOYLE, and S. S. ZILVA. The antiscurvy vitamin in apples.** *Med. Res. Council Spec. Rept. Ser.* [*London*] 146: 5-45. 1930.—The Bramley's Seedling was decidedly more active in antiscorbutic potency than the other varieties tested. The character of the soil, the age of the tree and the season appeared to have no effect on this potency. Bramley's Seedlings picked from the same tree 14 days before the normal crop were of approximately the same antiscorbutic activity as apples of the normal crop. There was little loss in the vitamin C content of apples stored at 1° C. in the air or at 10° C. in a mixture of carbon-dioxide, nitrogen and oxygen for about 3 months. The gas-stored apples showed a greater loss of the vitamin. The activity was higher in imported dessert apples in which the time elapsing between picking and testing was shortest. No marked difference in activity could be correlated with difference in variety. The heating of Bramley's Seedlings in their skins hardly affected their antiscorbutic activity.—*H. C. Koser.*

15798. **COWARD, KATHARINE H., BARBARA G. E. MORGAN, and F. J. DYER. The influence of vitamin A deficiency on the oestrous cycle of the rat. II.** *Jour. Physiol.* [*London*] 69(3): 349-352. 2 fig. 1930.—A series of ♀ rats (number not stated) were treated like the animals in experiments described in a previous paper, except that extracted light-white casein was substituted for vitamin-free casein ("Glaxo") in the diet. The results are divided into 3 groups. Group 1. The rats ceased to grow some time after the vagina opened; in these the authors found no normal cycles, but, after some days, cornified cells occurred continuously for as much as 21 days before they considered the rats steady in weight and ready to be given the dose of cod-liver oil. After the giving of cod-liver oil, regular cycles were sooner or later resumed. This result confirms the finding

of Evans and Bishop, and of Macy, Outhouse, Long and Graham. Group 2. The rats became steady in weight; they were given cod-liver oil and they grew for 8 to 17 days before the vaginas opened. In these rats regular cycles were not established for some time after the giving of cod-liver oil, leukocytes only appearing in the vagina for about 14 days. This result is exactly what the authors found at times in their previous work when they used "vitamin-free" casein ("Glaxo"), and confirms their conclusion that it is impossible to rely solely on the continuous occurrence of cornified cells in the vagina as a criterion of vitamin A deficiency. Group 3. The vaginas of the rats opened some time before growth ceased, but few cycles occurred and there was no long period of continuous occurrence of cornified cells. Thus vitamin A deficiency completely failed to manifest itself by this symptom.

15799. DELBET, PIERRE, et PALIOS. Action du chlorure de magnésium sur les cobayes en carence scorbutique. *Compt. Rend. Soc. Biol.* 98(17): 1534-1536. 1928.—$MgCl_2$ added to a scorbutic diet prolonged the survival over the controls. Since the control diet was not entirely free of Mg, the authors conclude that it was not absence of Mg, but the amount absorbed which was effective, possibly aiding in certain syntheses inhibited by the absence of vitamin C.

15800. GOTHLIN, GUSTAF F. A method of establishing the vitamin C standard and requirements of physically healthy individuals by testing the strength of their cutaneous capillaries. *Skand. Arch. Physiol.* 61(6): 225-270. 3 fig. 1931.—The author had 3 objectives in this research; to elaborate an indirect method of determining an individual's vitamin C status; to determine by this method the adult human vitamin C requirements; and to ascertain whether the Swedish people at all seasons were adequately supplied with vitamin C. Since the strength of the capillaries in withstanding pressure might be used to indicate whether the antiscorbutic vitamin was sufficient, the clinical "capillary resistance test" used in the study of scurvy was developed in a quantitative way. Pressure within the capillaries was regulated by a compression band around the arm. The external pressure must always be less than the diastolic pressure of the affluent artery, and should be applied for 15 min. Three levels of pressure, 35, 50 and 65 mm. are used, and the capillary hemorrhages in a 6 cm. circle at the elbow are counted after each period of pressure. Four grades of capillary strength have thus been established: I, no hemorrhages below 65 mm. Hg pressure; II, hemorrhages at 50 mm., but not more than 6; III, more than 6 hemorrhages at 50 mm. but none at 35 mm.; IV, at least 2 hemorrhages at 35 mm. The test was shown to be practical, for by placing two healthy individuals on a scorbutic diet, in a few weeks the strength of their cutaneous capillaries fell to an abnormally low level, but it gradually returned when the amount of antiscorbutic vitamin was kept adequate. By examination of persons belonging to the Nordic race it was ascertained that the vitamin C standard for that race is normal when the number of capillary hemorrhages in response to an external pressure of 50 mm. is less than 5. More than 8 is definitely subnormal. With the capillary strength test as a criterion the minimum antiscorbutic protective dose for a male individual (dementia praecox, but otherwise healthy) was 0.7 cc. of orange juice per day per kgm.; for a female in the same institution the dose was 1 cc. The susceptibility to scurvy is thus 9 to 13 times less in man than in young guinea pigs. The formerly unknown minimum antiscorbutic dose for adult man may thus be determined from the minimum guinea pig dose. For a human being weighing 60 kgm. it may be found by multiplying the minimum guinea pig dose by a coefficient lying between 14 and 20. For the guinea pig the minimum antiscorbutic protective dose of milk from cows at pasture was 50 cc. Soured milk was not inferior to fresh. After slow pasteurization the great loss of vitamin C should be compensated by the addition to the diet of such foodstuffs as potatoes and oranges. In April and May, the time at which the probability of vitamin C undernourishment is greatest in Sweden, 18% of children between 11 and 15 years showed a deficiency. Ordinary summer country life brought about a return to normal in their capillary strength.—*W. J. Meek.*

15801. HART, E. B., O. L. KLINE, and J. A. KEENAN. A ration for the production of rickets in chicks. *Science* 73(1904): 710-711. 1931.—Day old chicks were fed for 5 weeks on the following ration: 59 parts of ground yellow corn; 25 wheat middlings (standard); 12 of crude casein; 1 of NaCl; 1 of precipitated $CaCO_3$; 1 of precipitated calcium phosphate; and 1 dried yeast. They became rachitic in 28-35 days, with an ash of extracted tibia approximating 30%. In presence of adequate supply of vitamin D, chicks fed this ration for 35 days gave an ash content of 43+% in the tibia.

15802. JANOWSKAJA, B. Über das Wesen der Bezssonoffschen Reaktion auf das Vitamin C. *Wiss. Arch. Landw. Abt. B, Arch. Tierernähr. u. Tierzucht.* 6 (2): 155-160. 1931.—In investigations on the behavior of the chromogenic material towards adsorbents the same reaction as is obtained with the chromogenic substance in lemon juice was obtained with other chemical compounds. The Bezssonoff reaction cannot be considered specific for Vitamin C.—*Author's summary (transl. by H. Levine).*

Gén.* 29(2): 270-276. 1931.—In scorbutic avitaminosis the disease-resistant powers of the organism are reduced, as shown by the behavior of the leucocytes, the local response to irritants, and the degree of alimentary autointoxication.—*W. R. Fearon.*

15805. LEVADITI, C., et LI YUAN PO. Étude expérimentale de l'ergostérol irradié. *Presse Méd.* 38(11): 168-172. 15 fig. [13 col.] 1930.—This study was undertaken to determine the exact toxicity of ergosterol for laboratory animals; to analyze the mechanism of the calcification of certain organs; and to provoke calcification of preexisting lesions due to infections. Irradiated ergosterol is not a simple chemical substance, but a mixture in variable proportions of pure, unchanged ergosterol, of ergopinacose (Windaus), sometimes of ergosterol peroxid, of vitamin D itself, which is of unknown chemical composition, and of various products of the partial destruction of that vitamin. Administration of irradiated ergosterol by mouth in varying doses to 44 mice, 23 rabbits, 3 kittens, 2 monkeys (1 *Cercopithecus callitrix* and 1 *Macacus rhesus*) and chickens, showed that this substance was perfectly tolerated by laboratory animals, including the monkey, in doses much higher than those used in human therapy. In heavy doses it was toxic, producing progressive emaciation and organic lesions sometimes, but not necessarily, accompanied by heterotopic calcification, due to a disturbance of Ca metabolism in the cytoplasm of certain cellular elements. The absorption of repeated sub-toxic doses produced neither habituation nor hypersensibility in the mouse and the rabbit. Blockage of the reticulo-endothelial system had no appreciable effect on the sensitiveness of the mouse to irradiated ergosterol. Calcification was produced in the kidney, aorta, digestive tube, lungs, liver and myocardium. Still, some animals died of ergosterol intoxication without showing any Ca deposits in the tissues. The mouse, the rabbit, the kitten and the rat were the only animals that showed any calcification worth mentioning. In animals already bearing organic lesions, however, irradiated ergosterol determines a calcification of those lesions. It appears to render experimental tuberculosis benign. Previous studies showed a spontaneous tendency of the lesions of herpetic encephalitis toward calcification. Oral doses of irradiated ergosterol assist in this calcification and aid in cicatricial repair.

Chem.* 85(2): 477-489. 2 fig. 1930. —The unsaponifiable portion of cod liver oil, tested according to technique of Norris and Danielson, produces no red coloration and the blue color is a linear function of the % concentration. Saturated fatty acids have no effect upon the color produced. Unsaturated acids show a slight inhibitory effect. Oleic acid, with increasing amounts, hastens the rate of fading of the blue color causing a rapid development of red coloration. At lower color values the curve approaches a linear function. A quantitative comparison between different oils can be made only at low color values or on the unsaponifiable portion.—*E. R. Loew.*

15809. **NORRIS, ROBERT J. The destruction of vitamin A by ultra-violet radiations.** *Bull. Basic Sci. Res. [Univ. Cincinnati]* 3(2): 89-100. 1931.—Biological and colorimetric assays of oils for vitamin A do not agree throughout the course of inactivation by irradiation with ultra-violet light. Oils irradiated until biologically inactive still showed 72 to 75% of their original vitamin potency as judged colorimetrically. Destruction of biological activity by irradiation proceeded rapidly after an initial induction period, in which there was little or no inactivation. Destruction of the chromogenic substance began immediately upon irradiation, without an induction period. It is concluded that the chromogenic substance is not vitamin A itself, but some closely associated substance.—*Author's summary.*

15822. **TAKEDA, KENJI. On the color reaction of vitamin A.** [In Japanese with English résumé.] *Tottori Nogaku-Kwaiho (Transl. Tottori Soc. Agric. Sci.)* 2(1): 1-44. 1930.—Three new color reactions are proposed for testing vitamin A: kaolin carbon bisulphide reaction, 1:120 $SbCl_5$ chloroform reaction, and 0.1% benzidin acetic acid reaction. The most reliable color reactions which can be applied for general purposes are the following: liquid $AsCl_3$, 1:120 $SbCl_3$, kaolin, fuller's earth, and 30% $SbCl_3$. The author prefers the $AsCl_3$ to the 30% $SbCl_3$ reaction; the latter is more unstable, especially in the mixed preparations.

15823. **THOMAS, BYRON H., and FLORENCE L. MacLEOD. Increasing the vitamin D potency of cow's milk by the daily feeding of irradiated yeast or irradiated ergosterol.** *Science* 73(1901): 618-620. 1931.— Preliminary report.

15824. **VEEN, A. G. van. Das antineuritische Vitamin. IV.** *Rec. Trav. Chim. Pays-Bas* 50(5): 610-616. 1931.— A method is given for the purification of extract containing the anti-neuritic vitamin.

15825. **WILLIAMS, R. R., ROBERT E. WATERMAN, and SAMUEL GURIN. The Jansen and Donath procedure for the isolation of antineuritic vitamin.** *Jour. Biol. Chem.* 87(3): 559-579. 1930.—The application of this procedure to rice polish led to larger losses of activity than those reported by the authors of the process. Applied to yeast the procedure led to still larger losses.

However, in the case of rice polish some of the final products, though non-crystalline, possessed physiological properties approximating those of Jansen and Donath's crystals. A sample of these crystals, kindly furnished by Dr. Jansen, permitted such a comparison to be made. With doses of 0.04 mgm. daily, polyneuritis and death were very much retarded in pigeons fed on polished rice *ad lib.* but weight loss was not avoided. The weight loss appears to be due to the absence from the highly purified products of something which was present in the original rice polish rather than to an insufficient quantity of antineuritic vitamin. The Jansen crystals in daily doses of 0.04 mgm. produced a marked growth response in young rats on a synthetic diet plus autoclaved yeast. The results of physiological tests, usually on both rats and pigeons, of the by-products of the fractionation are also reported.—*R. R. Williams.*

15826. WRIGHT, A. M., and H. O. ASKEW. Colorimetric estimation of vitamin A in fats. *New Zealand Jour. Sci. and Tech.* 11(5): 344-348. 1930.—A brief critical study of the $SbCl_3$ test, with reference to the effect of delayed observation, rancidity, etc., on the color developed (in Lovibond units). Tests seem to indicate the presence of vitamin A in tallow.

15827. YUDKIN, ARTHUR M., MAX KRISS, and ARTHUR H. SMITH. Vitamin A potency of retinal tissue. *Amer. Jour. Physiol.* 97(4): 611-616. 1931.—Of 33 rats kept on vitamin A-free basal diet, 4 were given daily supplements of 20 mgm. pig's retina, 4 received 100 mgm. butterfat, and 3 received no supplement; the remaining 22 received no supplementary food until signs of ophthalmia appeared; then 6 received each 50 mgm. retina, 6, 30 mgm., 5, 20 mgm., 4, 50 mgm. choroid, and 1, 100 mgm. butterfat. In the 6 rats given 50 mgm. and in the 6 given 30 mgm. of dried retina daily after the development of ocular symptoms, the eyes were restored to normal appearance in 3-7 days and in 5-11 days respectively; growth was normal during life, and nutrition found good at necropsy. Of the 5 rats receiving 20 mgm. retina daily, in 4 the ocular symptoms cleared up, but slowly. Growth was resumed, also slowly. Choroid induced no improvement of ocular symptoms and very slow growth; leg weakness or posterior paralysis occurred in the 4 animals of this group.

15831. ASHER, LEON, und HANS WAGNER. Untersuchungen über die Spezifität der Asherschen Methode der Prüfung der Schilddrüsenfunktion durch Sauerstoffmangel. *Zeitschr. Ges. Exp. Med.* 68(1/4): 32-81. 1 fig. 1929.—Rats and guinea pigs were placed in an air tight glass bell jar until symptoms of anoxemia appeared. The CO_2 was absorbed by KOH, and the pressure as it was reduced by the consumption of O was kept normal by the introduction of H. Animals fed with desiccated thyroid or injected with a thyroid extract showed a much more marked susceptibility to O deficiency than normal animals. The susceptibility was more marked in the animals fed per os than in those injected subcutaneously. The oral feeding and subcutaneous injection of splenic, thymic, and testicular substances did not influence the effects of O deficiency. The administration of thyroid and thymus together produced the same result as of thyroid alone. The conclusion is that the increased sensitivity to O deficiency is a specific reaction of increased thyroid function.—*L. Seed.*

15832. BACQ, Z. M., and S. DWORKIN. The action of parathyroid extract in sympathectomized animals. *Amer. Jour. Physiol.* 95(3): 614-619. 1930.—Responses (increase of blood Ca, muscular weakness, polypnea, etc.) to parathyroid extract (Parathormone) were displayed by 6 normal cats, essentially similar to those observed in dogs by previous investigators. Toxic symptoms occurred after prolonged administration, but the time of onset did not correspond to the highest blood Ca level. In 6 sympathectomized cats and 2 sympathectomized dogs the basal level of blood Ca was not outside the average range for normal animals (confirming the findings of Lamelas, 1930). The absence of central sympathetic nervous impulses did not appreciably influence the response of cats and dogs to parathyroid extract.

15833. BARTOLI, OTTORINO. Paratiroidi e rigenerazione muscolare. [The parathyroids and muscular regeneration.] *Policlinico (Sez. Chir.)* 37(10): 469-475. 1930.—Pieces of muscle were excised from a hind foot of each of 40 guinea-pigs; 20 were injected with varying doses of parathyroid extract (0.15-5.5 gm.); 10 received injections of 1.6-8 gm. of heterogeneous proteins, and 10 controls were not treated. The animals were killed 2-90 days after operation, and the scar tissues examined. The regeneration of the tissues did not appear either to be retarded or accelerated by the treatment, and no complete anatomic reconstitution of the continuity of the muscular fibers was observed.

15834. BERGER, LOUIS. La neurocrinie: considération histologique sur le mécanisme de la secretion interne. *Presse Méd.* 38(101): 1729-1731. 6 fig. 1930.—The endocrine glands are generally understood to discharge their secretions into the blood stream. Berger maintains that there are 2 classes of endocrine glands, which he terms hemocrine and neurocrine respectively; the latter discharge their secretions along the nerves. Foreign toxins, like those of tetanus and diphtheria, he says, act in this manner; why not the products of normal metabolism? He offers histologic evidence that the testicle and the hypophysis represent the neurocrine type of glands.

15835. **BOETERS, HEINZ. Prolanversuche an jungen männlichen Ratten.** *Deutsche Med. Wochenschr.* 56 (33) : 1382-1385. 1930.—The series included 54 controls and 68 experimental rats. Prolan exercised, in moderate doses, a maturing effect on the fetal and infantile germinative tissue. In animals advancing toward maturity the maturing effect was weaker; larger doses injured the germinative tissue while producing hyperplasia of the interstitial tissue and in extreme cases marked increase of the sexual organs. Of 6 ♂ and 4 ♀ rats, the increase in body weight of the 3 ♂♂ and 2 ♀♀ receiving prolan was 23-29% as against 38-53% for the 3 ♂ and 2 ♀ controls.

15836. **BORST, M., A. DÖDERLEIN, und D. GOSTIMIROVIÉ. Geschlechtsphysiologische Studien. I. Mitteilung. Ueber die Einwirkung des Hypophysenvorderlappenhormons (Prolan) auf juvenile männliche Mäuse.** *Münchener Med. Wochenschr.* 77 (12) : 473-475. 1930. —Within 100 hrs. large doses of prolan produced histologically demonstrable effects on the young ♂ mouse, involving primarily the generative portion of the testicle and altogether comparable to those produced on the young ♀ mouse. In the ♂ subjects prolan produced rapid division of spermatogonia and spermatocytes not seen in controls, both series of animals being not more than 26 days old at death.

15837. **CAYLOR, HAROLD D., and CARL F. SCHLOTTHAUER. The influence of diet in the development of myxedema in thyroidectomized pigs.** *Amer. Jour. Physiol.* 89 (3) : 596-600. 1929.—Of 10 Duroc pigs 2 mos. old (5 [Group 1] on a low protein, high carbohydrate diet and 5 [Group 2] on a high protein, low carbohydrate diet), 2 in each group were thyroidectomized, the other 3 serving as controls. In Group 1 the 3 normal controls gained more weight than their thyroidectomized litter mates, which, however, did not develop myxedema and remained as alert as the normal controls. In Group 2 the thyroidectomized swine grew in stature equal to their litter mate controls, made greater gains in weight, but developed myxedema, losing the natural curiosity characteristic of normal young pigs, becoming stupid and inert. This indicates that the quantity of protein in the diet is of significance in the development of the edema of myxedema in thyroidectomized swine, and suggests that the mental retardation seen in myxedema patients may be due in part to pressure from edema in the central nervous system.

15838. **CHAMBERLAIN, E. NOBLE. The effect of insulin and other endocrine extracts on the cholesterol content of tissues.** *Jour. Physiol.* 70 (4) : 441-448. 1930. —Experiments were made to determine the effects of overdosage with endocrine extracts on the cholesterol content of the suprarenals and other tissues. The extracts used were thyroid, "pituitrin" and insulin. The following results were obtained: 1) With thyroid feeding [in 7 rabbits] no significant changes in any tissues. The weight of the adrenals, however, did not diminish in proportion to the body weight if the loss of weight was severe. 2) "Pituitrin" produced no changes [in 12 rabbits]. 3) Insulin [in 18 rabbits] caused a marked decrease in the cholesterol content of the suprarenals, but this effect was not so pronounced if the hypoglycemia was prevented by simultaneous administration of glucose. None of the extracts produced any material changes in the cholesterol content of blood, liver or spleen. It is suggested that the synthesis of cholesterol by the suprarenal glands is controlled by the internal secretion of the pancreas.—*Author's summary.*

15839. **COGNETTI de MARTIIS, LUIGI. Contributo alla conoscenza della distruzione fisiologica dei prodotti sessuali maschili. [Physiological destruction of the male sex products.]** *Boll. Mus. Zool. e Anat. Comp. R. Univ. Genova* 10 (33) : 1-16. 1930.—Numerous findings on various types of animals have corroborated the author's work (1910) on the physiological destruction of the male sex products. Such physiological destruction is correlated with the production of the hormone. Schieffendecker (1904) and Cunningham (1908) are to be accorded priority, rather than Cattaneo (1913), as the first to consider hormones as developmental factors.—*L. Cognetti de Martiis (transl. by R. A. Muttkowski).*

15840. **COREY, E. L. Foetal and early postnatal responses of rat gonads to pituitary injections.** *Physiol. Zool.* 3 (3) : 379-391. 8 fig. 1930.—An attempt was made to ascertain the time at which the mammalian organism first shows a positive response to the pituitary secretion. Fetal and newborn albino rats were subjected to the injection of fresh, macerated, whole pituitary gland from adult albino rats, in physiological saline solution and fresh blood plasma. The results were practically identical, irrespective of the medium employed. Accelerated differentiation in the gonad was selected as an indication of response to injection. No reaction to pituitary injection was observed in the fetal rat of either sex. Accelerated differentiation was observed in the ♂ on the 10th day of postnatal life, following the daily injection of pituitary substance. In the ♀ a similar reaction was observed 15 days after parturition. The reaction of the gonad to pituitary injection manifested itself in the ♂ in an altered histological picture, due to increased tubular length and diam., as well as to an increase in the size of the interstitial cells. An increased number of cells over those present in the controls was seen within the germinal epithelium. Increase in follicular size and the amount of follicular fluid present indicated a response to pituitary injection in the ♀.—*Author (courtesy Wistar. Bibl. Serv.).*

15841. **CROWDEN, G. P. The replacement of depleted adrenaline in the suprarenals.** *Jour. Physiol.* 68 (3) : 313-323. 5 fig. 1929.—By subjecting 13 cats to prolonged chilling, the adrenin in the adrenal glands was markedly reduced. The replacement of adrenin, when the animals were placed in warm surroundings, was followed by the Folin-Dennis-Cannon method. It was found that recovery occurred in denervated as well as innervated glands.—*J. C. Donaldson.*

15842. **DINGEMANSE, E., und S. E. deJONGH. Die Mehrheit der Sexualhormone der Hypophysis; Wirkung auf weibliche Tiere.** *Pflüger's Arch. Ges. Physiol.* 226 (4/5) : 543-546. 1931.—The authors support the thesis that urine of pregnancy contains 2 hormones of hypophyseal origin: (1) a follicular growth hormone, and (2) a luteinising hormone.—*M. H. Friedman.*

15843. **DINGEMANSE, E., J. FREUD, S. KOBER, E. LAQUEUR, A. LUCHS, und A. W. P. MÜNCH. Zur Trennung des männlichen (Sexual-) Hormons vom weiblichen (Menformon).** *Biochem. Zeitschr.* 231 (1/3) : 1-5. 1931.—Since extract of testes and urine from ♂♂ contains ♀ hormone, a method of separation was developed, in the course of which it was found that the ♂ hormone, in contrast to menformon, has a basic rather than an acid character.

15845. **DOISY, EDWARD A., SIDNEY THAYER, and CLEMENT D. VELER. The crystals of the follicular ovarian hormone.** *Proc. Soc. Exp. Biol. & Med.* 27 (5) : 417-419. 1930.

15846. **EUFINGER, H., und H. WIESBADER. Reid Huntsche Reaktion und Schwangerschaft. II.** *Arch. Gynäkol.* 142 (3) : 662-667. 1930.—In 45 white mice the hormone of the anterior lobe of hypophysis produced a great rise in the acetonitril resistance (33 mice surviving while all the controls died), apparently independent in degree of the amount of hormone. In 30 mice ovarian hormone produced a slighter rise in resistance, 13 of the treated mice surviving. Of 35 animals treated with the urine of pregnant women, 13 survived varying doses of acetonitril poisoning, as against 1 of (apparently 4) controls. The authors conclude that the outcome of the Reid Hunt reaction in mice previously treated with urine from pregnant women does not indicate with any cer-

tainty the increase in the blood of pregnancy of thyroxin-like substances. They incline to believe that hormone of the anterior lobe of the hypophysis, and perhaps also ovarian hormone, increases resistance to acetonitril poisoning.

15847. **FENGER, F., R. H. ANDREW, and J. J. VOLLERTSEN.** Geographic location and the iodine content of the thyroid gland. *Jour. Amer. Chem. Soc.* 53(1): 237-239. 1931.—Calculated on the desiccated fat-free basis, the yearly average for hog thyroid glands from North Dakota is 0.32% I, while that of Texas glands is 0.60% I. The seasonal variation in the I content is most pronounced in the northern glands. The higher I level of the Texas glands and the greater seasonal fluctuations of the North Dakota thyroids are attributed to the geographic location of the two states.—*Authors' conclusions.*

15848. **FEVOLD, H. L., F. L. HISAW, and S. L. LEONARD.** The gonad stimulating and the luteinizing hormones of the anterior lobe of the hypophysis. *Amer. Jour. Physiol.* 97(2): 291-301. 5 fig. 1931.—Experiments on immature ♀ rats (representative results from 6 cited) show that the anterior lobe secretes 2 hormones which act on the ovary; a gonad stimulating factor which stimulates follicular growth, and a luteinizing factor which causes lutein growth. These have been extracted quantitatively from dried anterior lobe by aqueous pyridine. The 2 hormones have been separated into 2 different preparations each giving a different physiological reaction. When the 2 fractions are again united the resulting preparation is entirely similar to the first crude extract. The luteinizing hormone cannot act on the immature ovary. The infantile ovary must be stimulated to follicular activity by the gonad stimulating hormone before a characteristic "mulberry" ovary can be produced.—*Authors' summary.*

15849. **FIROR, W. M., and G. S. EADIE.** The effect of epinephrine on muscle glycogen in the absence of the liver, and a modification of the operation for liver removal. *Amer. Jour. Physiol.* 94(3): 615-618. 1930.—The liver was totally extirpated in 14 cats to determine if a decrease of muscle glycogen would follow, indicating a peripheral action of epinephrine on carbohydrates. No sign of peripheral action of epinephrine was obtained, either on muscle glycogen or on the rate at which glucose leaves the blood (the latter confirming the work of Soskin). These results differ from the work of Cori and Cori, possibly, it is suggested, because of technic and because of the difference between the rat and the cat.

15850. **FRIEDMAN, J. L., and L. B. NICE.** Multiple ovaries and the oestrous cycle in the white rat. *Amer. Jour. Physiol.* 95(1): 40-42. 1930.—Multiple ovarian transplants in [22] normal ♀ rats nearly doubled the number of oestrous cycles as demonstrated by the vaginal smear method. The voluntary activity of these rats was not markedly increased after the operation. Pseudopregnancy was induced in 10 of the 19 animals by the glass rod stimulation of Long and Evans. Exposure to a vasectomized ♂ produced this condition in 9 of these rats.—*Authors' summary.*

15851. **GANFINI, G.** Azione della placenta sulla metamorfosi e sullo sviluppo della muscolatura liscia nei girini. [Action of placenta on metamorphosis and development of smooth muscle in tadpoles.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 949-953. 4 fig. 1930.—In raw and cooked placenta substances are contained (in smaller amount than in muscle) which stimulate development and metamorphosis of tadpoles, and activate development of smooth muscle.—*M. Comel.*

15852. **GANFINI, G.** Paratiroidi ed ergosterolo irradiato. [Parathyroid glands and irradiated ergosterol.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 953-955. 1930.—Irradiated ergosterol cannot replace parathyroid hormone; it merely delays the onset of tetany, without influencing the cachexia.—*M. Comel.*

15853. **GERÉB, PAUL.** Über den Einfluss der weiblichen Geschlechtshormone auf die juvenilen männlichen Keimdrüsen. Die Wirkung des Schwangerenurins auf die männlichen Keimdrüsen bei juvenilen weissen Mäusen. *Zeitschr. Geburtsh. u. Gynäkol.* 99(3): 443-451. 5 fig. 1931.—Filtered pregnancy urine 0.3-0.4 cc. twice daily for 3 days, at least 4 hrs. elapsing between any 2 injections, was injected into 105 white mice (29 controls), which were killed 1 day after last injection. In 89 mice the testes were distinctly enlarged, in 16 they showed little or no change; controls were unchanged. Examination revealed premature, pronounced spermatogenesis (grade II). The urine was freed of prolan by heating to 100° for ½ min.; 84 mice were injected as before (21 controls). Macroscopically the genitalia were unchanged; microscopically, spermatogenesis: grade I in 60, 24 unaffected. Mice (20) treated with boiled urine extracted with ether to remove the ♀ hormone showed no change in the testis. Spermatogenesis grade II occurred within 100 hrs. in 13 of 15 mice treated with 5-10 mouse units daily of folliculin or sistomensin. Using urine positive and negative to the Aschheim-Zondek reaction (A.-Z. R.), some extracted with ether to remove the ♀ hormone, and the same technic, it was found that A.-Z.R. II and III urine gave spermatogenesis grade II. With negative urine 17 tests were negative, 3 positive; of these negatives 11 showed A.-Z.R. I before ether extraction. While spermatogenesis can be called forth by the ♀ hormone it is always and distinctly less than with hormone of the anterior lobe of the hypophysis.

15854. **GRÜTER, F.** Aktivierung von somatisch-psychisch unterentwickelten Zuchttieren durch Anreicherung des Keimdrüsenhormons. *Arch. Frauenk.* 16(4): 279-287. 6 fig. 1931.—In 17 infantile bulls testicular transplants produced full development in 11, had no action in 6. In some cases the improvement lasted for yrs. Transplantation of ovarian tissue into 60 cows (castrated, infantile, or with atrophic ovaries) resulted in increased milk production or conception in a large proportion. In prepubertal cattle (number not stated) transplantation of sex glands hastened maturity. In a young bull calf implanted with ovarian tissue development appeared inhibited; the opposite procedure did not seem to affect development. In 20 bulls in which vasoligature was performed, reactivation was obtained in 15.

15855. **GRÜTER, F.** Hypophysen-Vorderlappen-Extrakt-Wirkungen auf kleine Laboratoriumstiere und auf Haustiere. *Arch. Frauenk.* 16(4): 287-295. 1931.—Of 6 goats, 2 normal and 2 thyroidectomized received 15 gm. anterior lobe extract, another normal received 3½ gm., and 1 received none. One normal and 1 thyroidectomized were lame for 2 days, the other 2 showed oestrus, unusual in the spring. The increase in milk secretion (animals in full lactation a short time after partus) was less pronounced with each injection, appearing in only 1 on the 4th injection. In contrast to the cow, the action was of short duration. After injection the milk was lower in sp. gr., in fat, and in dry matter than in controls. This was more pronounced in the animals which were also thyroidectomized. Thyroidectomy reduced the quantity of milk by ½. The mineral content of the milk was somewhat increased by injection if the thyroid gland was retained. Phosphoric acid and Ca were greatly increased if the thyroid was present, otherwise phosphoric acid was somewhat, and Ca greatly, lowered. Cl was greatly increased and unaffected by the thyroid. The other minerals were remarkably constant. The alkalinity of the minerals in cow's milk was weakly positive, in goat's milk weakly positive or negative, thyroidectomy seeming to promote acidity. Two and 3 injections of anterior lobe of the pituitary into 2 bulls that had regressed in reproductive ability brought reactivation; in 3 infantile bulls 4-5 injections were ineffective.

15856. **HARTMAN, FRANK A., KATHARINE A. BROWNELL, and WARREN E. HARTMAN.** A further study of the hormone of the adrenal cortex. *Amer. Jour. Physiol.* 95(3): 670-680. 1930.—Cats whose adrenals are removed in 2 stages survive 6-11 days when untreated. Those injected with a small quantity of isotonic salt solution survived the shorter period. Increase in the

interval between the operations, above a few days, does not lengthen the survival period. An increase in the operation time when not too great does not decrease the survival period. Adrenalectomized animals show considerable loss in weight if they survive many days. Cortin, the hormone of the adrenal cortex which is essential to life, is carried down by the precipitated material formed when NaCl is added to the point of saturation or below. Adrenalectomized cats treated with an extract made from such a precipitate survived an average of 26.4 days. Heating the NaCl precipitate extract to 80° C. for 5 min. destroys its potency. Precipitation of the protein in the NaCl precipitate extract by ethyl alcohol does not diminish the potency. A concentrated preparation of cortin can be made by extracting the cortex with ethyl ether which dissolves very little epinephrine. The ether is removed by distillation, the residue being extracted with warm 80% ethyl alcohol. Much inert material is removed by chilling and filtering. After removing the alcohol, the residue is taken up in water. The aqueous solution contains the cortin. This extract acts as a substitute for the adrenal cortex. Adrenalectomized cats are being kept alive in good condition indefinitely by its use. The growth of young rats whose adrenals have been removed has been maintained until the adult stage is reached by injecting the extract. Such rats behave normally in every way, even to raising litters. Cortin treated adrenalectomized cats eat well, gain in weight, play, fight and act like normals. Cortin lowers the blood urea when high. It increases the resistance to infection and cold. It speeds the repair of injury and enables the animal to withstand operative or other trauma. By its use it is possible to remove both adrenals at 1 operation and maintain life indefinitely. Animals allowed to pass into the last stages of adrenal insufficiency which just precede death have been revived by cortin. A case of Addison's disease with a systolic blood pressure of 50 mm. and a pulse of 120 per min. together with other characteristic symptoms has been revived by the use of cortin. Cortin is apparently not effective by mouth. When given subcutaneously one can begin to detect its effects in a few hours.—*Authors' summary.*

15857. **HIRSCH, MAX. Handbuch der inneren Sekretion. Eine umfassende Darstellung der Anatomie, Physiologie und Pathologie der endokrinen Drüsen. [Handbook of internal secretion. Anatomy, physiology and pathology of the endocrine glands.]** 1428p. 173 fig. Curt Kabitzsch: 1929. Pr. 135 M.

15858. **HOFBAUER, J. Concerning the etiology of hyperplasia of the endometrium.** *Surg., Gynecol. and Obstetr.* 52(2): 222-227. 5 fig. 1931.—In an unstated proportion of 28 guinea pigs treated parenterally with extract of beef anterior pituitary, and more markedly in 18 guinea pigs into which bits of fresh anterior pituitary were transplanted there were produced (so long as the ovaries were preserved) conditions in the uterine mucosa and the ovaries practically identical with those in human endometrial hyperplasia; after oöphorectomy the process was limited to the basal portion of the endometrium. These observations suggest that hyperplasia may reasonably be regarded as the manifestation of an overactivity of the anterior pituitary lobe, the internal secretion of the ovary being essential for the changes occurring in the upper part of the uterine mucosa, while the basal layer is entirely under the control of the anterior pituitary lobe.

15859. **HORSTERS, HANS. Stoffwechselversuche mit Hormonpräparaten an Kaninchen.** *Zeitschr. Ges. Exp. Med.* 73(1/2): 167-179. 1930.—Anterior lobe of hypophysis (substance and 2 preparations, used on 2 ♀, including 1 pregnant, and 2 ♂ rabbits) produced an extreme rise in urinary phosphate excretion, amounting in some cases to more than 500%; generally a decrease in NaCl excretion and a phosphate retention in the feces. Posterior lobe of hypophysis (2 preparations, used on 1 pregnant and 3 ♂ rabbits), during the experimental period produced a retention of urine and of urinary phosphate and NaCl, followed by excessive excretion of urine and of both constituents. Placenta hormone (progynon, used on 1 ♀ rabbit) caused retention of phosphate and NaCl, with hypercalcemia and hypercholesteremia. Epinephrine (suprarenin, used on 2 ♂ rabbits) produced marked decrease in total urine, retention of NaCl, and increase of fecal P, with striking rise of total acid-soluble (organic) P in the blood. Thyroxin (used on 2 ♂ rabbits) produced increase in total urine, urinary phosphate and NaCl and fecal P. Parathyroid extract (used on 2 ♂ rabbits) decreased the total urine, urinary NaCl and fecal phosphate, with decrease of urinary phosphate in 1 case and no change in the other.

15860. **HOUSSAY, B. A., y A. BIASOTTI. Sobre la substancia hipofisaria que refuerza la diabetes pancreática. [Diabetogenic substance of the anterior pituitary.]** *Rev. Soc. Argentina Biol.* 7(1): 3-12. 1931.—Hypophysectomy antagonizes the appearance of pancreatic diabetes in toads; subcutaneous implantation of 1 or 2 glandular lobes (anterior lobe of mammals) is followed by an intense diabetes. The intermediate-neural lobe (posterior lobe of mammals) is less active and all other organs of the toad tested were inactive. This same activity was found in the anterior pituitary of fishes, batrachians, birds and mammals, including man. The anterior lobe kept in acetone maintains its activity. The active principle is soluble in water and 60% alcohol, insoluble in absolute alcohol, ether, acetone, chloroform and benzene; it is destroyed at 100°C., does not pass the ultrafilter and is easily absorbed. It differs from the principle with sexual activity in that it is equally active in all species whatever its origin.—*J. T. Lewis.*

15861. **IVY, A. C., G. KLOSTER, H. C. LUETH, and G. E. DREWYER. On the preparation of "cholecystokinin."** *Amer. Jour. Physiol.* 91(1): 336-344. 1929.—A method is outlined for the preparation of "cholecystokinin," which yields a uniform product containing 3-4 doses of secretin for 1 of "cholecystokinin," free of vasodepressor action, and causing gall-bladder contraction in 3-6 mgm. doses (from dog's mucosa) and in 5-10 mgm. (from hog's mucosa) doses, when administered intravenously. The authors can make a solution which contains secretin but no "cholecystokinin," and a solution which contains "cholecystokinin," but no secretin. This observation leads to the conclusion that "cholecystokinin" is not secretin.—*Authors' summary.*

15862. **JONGH, S. E. de. Die Wirkung der Sexualhormone der Hypophyse auf männliche Tiere.** *Pflüger's Arch. Ges. Physiol.* 226(4/5): 547-558. 5 fig. 1931.—Following the injection of extracts of urine of pregnancy into immature male mice, no significant changes in the weight of the testicles were noted, nor was spermatogenesis affected. The accessory genitals, however, especially the seminal vesicles, showed marked increase in weight. Histological study of the testicle revealed some changes which might be interpreted as growth of interstitial cells in the treated animals. From parallel experiments on immature females, it seems that the factor responsible for the effects in the male is the B factor (luteinising). —*M. H. Friedman.*

15863. **JONGH, S. E. de, und ERNST LAQUEUR. Antagonismus von Menformon und Hormonen des Hypophysenvorderlappens.** *Pflüger's Arch. Ges. Physiol.* 227 (1/2): 57-70. 2 fig. 1931.—In immature and mature male mice the effects of menformon and "anterior pituitary hormone" on the accessory genitalia were determined. The authors interpret their results as showing that relatively large doses (as high as 40 units) of menformon inhibit the usual stimulating effects of the "anterior pituitary hormone" on the accessory organs of the male. It was noted, however, that in males injected with "anterior pituitary hormone," menformon was incapable of producing testicular atrophy.—*M. H. Friedman.*

15864. **JUHN, MARY, F. D'AMOUR, and E. B. WOMACK. The effects of simultaneous injections of the female and male hormones in capons.** *Amer. Jour. Physiol.* 95(3): 641-649. 1 pl. 1930.—The effects of combined injections of the ♀ and ♂ hormones and of alternate in-

jections on successive days were studied in [5] adult capons. The birds receiving the simultaneous injections developed ♀ plumage and ♂ headfurnishings. The same results were obtained when the hormones were mixed "in vitro" for 24 hrs. and 48 hrs. respectively previous to injection. When the hormones were administered in the same concentration but on alternate days ♀ plumage was not obtained and the headfurnishings showed only very slight growth. There are no indications of an antagonism between the chemically prepared sex hormones with the preparations used in the adult capon, neither is there an intensification of the action of 1 hormone in the presence of the other.—*Authors' summary.*

15865. **KORENCHEVSKY, VLADIMIR. The influence of the hypophysis on metabolism, growth and sexual organs of male rats and rabbits. II. Influence of extracts of hypophysis on the body weight, weight of fat, of sexual organs and of endocrine organs of rats.** *Biochem. Jour.* 24(2): 383-393. 1930.—A slightly alkaline extract, about pH 7.4 was prepared from the anterior lobe of the pituitary (ox) which had been ground with glycerol, kept at −5° and injected intraperitoneally into normal, cryptorchid and castrated young and adult male rats in amounts of from 1 to 2 cc. No decided influence was noticed on the growth of the animals as judged by weight. Body fat as judged by the intra-abdominal fat was decreased on the average by about 24%. Under the influence of injections of the extract the weight of penis, testes, and prostate with seminal vesicles was decreased to the greatest extent in cryptorchid animals (on an average for these organs by 31, 30 and 62% respectively). This effect was less noticeable in normal and absent in castrated rats. The weight of the thyroids was decreased by about 17% in normal and cryptorchid animals, but not significantly in castrated rats. It is concluded that the anterior lobe contains substances diminishing the weights of the penis, prostate, seminal vesicles, testes, thyroids and decreasing fat deposition and N metabolism.—*V. Korenchevsky.*

15866. **LEINATI, FAUSTO. Sulla liponecrosi sperimentale del sottocutaneo. (Nota seconda.) [Experimental subcutaneous liponecrosis.]** *Minerva Med.* 9(36): 372-382. 12 fig. 1929.—When experimental liponecroses were produced in rabbits and guinea pigs from which gonads and thyroid had been removed, the animals put on a large amount of fat, and great tumefactions occurred at the points of trauma, in which small foci of subcutaneous liponecrosis could be found. Apart from the greater obesity the results were about as reported in the author's first note, when only one type of gland was removed at a time.—*F. Leinati (transl. by P. Popenoe).*

15867. **LUDWIG, F., und J. von RIES. Die Beeinflussung des Brunsthormons durch Röntgen-, Rot- und Ultravioletstrahlen.** *Zentralbl. Gynäkol.* 55(3): 137-139. 1931.—No alteration in the action of the follicular hormone (progynon-P.) was observed in the mouse test after irradiation with 2000 R. Ultraviolet light (2-4 hrs., 60 cm.) rendered P. inactive. Irradiated with red light (3-5 hrs., 200 watt lamp, 40 cm. distance) activity increased and the vaginal reaction became particularly pronounced. While ½ mouse unit of normal P. called forth a slight vaginal reaction, when irradiated with red light ½ unit called forth a pronounced reaction; ¼ unit still showed a reaction but 1/10 mouse unit was inactive. Hormone rendered inactive by U.V. could be reactivated by red light as shown by the vaginal reaction.

15868. **LUETH, H. C., A. C. IVY, and G. KLOSTER. Further observations on the action of "cholecystokinin."** *Amer. Jour. Physiol.* 91(1): 329-335. 1929.—The gall bladder has been observed to contract under direct vision following the injection of "cholecystokinin." This has no effect on liver volume. If vasodilatin is present in the preparation of "cholecystokinin," the change in intra-gall-bladder pressure lasts much longer than the change in liver volume due to the dilatin. "Cholecystokinin" has no detectable effect on gastric motility. Its effect on intestinal motility is variable. Morphine hypodermically in some animals causes an exaggerated "tonus rhythm" of the gall bladder, which is not materially affected by atropine. Atropine, however, causes some relaxation of the gall bladder. Bile and bile salts administered intravenously cause a relaxation of the gall bladder in effective doses. Ergotamine tartrate stimulates the gall bladder and has no effect on "cholecystokinin" action. $MgSO_4$ in 200 mgm. doses (30 lb. dog) diminishes the "cholecystokinin" action, but does not abolish it. The diaphragm, thoracic and abdominal muscles play no part in the action of "cholecystokinin" on the gall bladder. An occasional spontaneous contraction of the gall bladder occurs in some dogs which cannot be accounted for. Dogs vary in their response to "cholecystokinin," the usual effect lasting 10-60 min. Occasionally the gall bladder will not relax, or return to normal for 2 or 3 hrs. after an injection. The gall bladder of the cat and dog are caused to contract on the intravenous administration of an adequate dose of "cholecystokinin." The authors failed to record a contraction for the gall bladder of the rabbit.—*Authors' summary.*

15869. **MACCHIARULO, O. Sull'azione morfogenetica della tiroide embrionale. [The morphogenetic action of embryonic thyroid gland.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 942-944. 1930.—Fetal thyroid gland exerts on tadpoles a morphogenetic influence qualitatively identical with that of thyroid glands of adult animals, the latter showing however a greater activity. The activity of fetal gland increases with fetal development. Functional activity is thus shown by the thyroid in prenatal life.—*M. Comel.*

15870. **McCLENDON, J. F., LILLAS MYRICK, CLAIRE CONKLIN, and I. H. WILSON. Ovarian hormone and metabolism.** *Amer. Jour. Physiol.* 97(1): 82-85. 1931.—In 23 women, aged 19-35 yrs. (mean 21.2 yrs.) the authors studied metabolism in the period between menstruations on the hypothesis that any changes are due to changes in concentration of hormone. They found a slight rise in basal metabolic rate. Since this rise is less than the daily variations, a large number of determinations (342) had to be made to reduce the probable error. The authors found an increase in the volume of the nipples during the same period. As the endometrium increases during this period, it seems possible that the rise in basal metabolic rate may be due to the growth of tissue in the endometrium and mammary glands. As to what hormones are concerned with these changes, the authors have only the report by McClendon and Burr that injection of follicular hormone increased the basal metabolic rate of 2 women lacking ovarian functions. There was no quantitative relation between the amount of hormone injected and the rise in basal metabolic rate. Probably a hormone from the corpus luteum causes the changes found, or they are due to more than 1 hormone.

15871. **MIGLIAVACCA, ANGELO. L'azione stimolante e sterilizzante sull'ovaio degli estratti testicolari in funzione della dose: il meccanismo della sterilizzazione. [Stimulating and sterilizing action on the ovary of testicular extracts as a function of the dosage.]** *Boll. Soc. Med.-Chir. Pavia* 44(3): 433-439. 1930.—An unspecified number of sexually mature ♀ guinea pigs and rats received intramuscular injections of homogeneous testicular extract and were killed 15-30 days later. The ovaries of animals treated with 0.25-0.5 cc. were hyperemic, remarkably rich in graafian follicles, the large majority in advanced stage of development and at the periphery of the ovary frequently reduced by the pressure of numbers to rectangular or irregularly polyhedral form with thin interfollicular walls, but the individual follicles normal and the ova very distinct. The author has never seen ovaries in similar functional condition in normal animals. Doses of 1-2 cc. produced in 15-30 days less hyperemia of the ovaries, fewer maturing follicles, but marked increase in subepithelial connective tissue. The strata of the germinative epithelium were increased all over the epithelial surface of the ovary with occasional marked invagination. In the ovaries of animals treated with 4 cc. extract the increase

of subepithelial connective tissue was still more marked; the tissue itself was more compact. The germinative epithelium was generally composed of a single layer, with only here and there a double or triple layer of epithelial cells. The majority of the follicles were atresic, with a thickened granulosa, pyknotic nuclei and chromatin broken into fragments; mitoses rather rare. Hence the action of testicular extract on the ovaries seems to be in direct relation to the quantity of the dose.

15872. **MITZKEVITCH, M. S. Die Abhängigkeit der formbildenden Reaktion von der Reife des Somas und der Anwesenheit des Geschlechtshormones.** *Endokrinologie* 6(3): 167-188. 6 fig. 1930.—The nipples of the guinea pig are used as indicators. Ovaries transplanted to castrated males produce development of nipples practically as large as in the normal female. The development of secondary sex characters is a double reaction based upon the age of the soma which permits the sex gland to produce the hormone which in turn compels the development of the nipple.—*B. Cunningham.*

15873. **MOLINENGO, L. Contributo allo studio della reazione ovarica nella topolina impubere all'azione dell-'orina di donna gravida. [Ovarian reaction in immature mice to the urine of the pregnant woman.]** *Clin. Ostetrica* 32(7): 385-395. 5 fig. 1930.—About 30 ♀ mice aged 3-4 wks. were subcutaneously injected with urine of pregnancy, divided into 3 series of 10 mice each, receiving 6 injections each of 0.2, 0.5 and 1 cc. each respectively. Of the 10 mice receiving 6 injections of 0.2 cc. each, 3 gave the 1st type of hypophyseal reaction and the other 7 the 1st and 2nd type. Of the 10 treated with 6 injections of 0.5 cc. each, 8 gave the 1st, 2nd and 3rd. Of the 10 receiving 6 injections of 1 cc. each 2 died after the 4th and 5th doses: the survivors without exception displayed the 3rd type of reaction (massive luteinization of the ovary, composed solely of atresic corpora lutea). The close relation of the degree of reaction to the amt. of the dose and the possibility of obtaining a follicular phase with small doses and hyperluteinization with large doses, in Molinengo's opinion militate against the theory of Evans and Simpson on the plurality of hypophyseal hormones.

15874. **MOORE, CARL R., and T. F. GALLAGHER. On the prevention of castration effects in mammals by testis extract injection.** *Amer. Jour. Physiol.* 89(2): 388-394. 1929.—In studying the effects of castration on rats and guinea pigs the authors obtained several physiological and morphological (gross and cytological) indicators of castration. Each alone is capable of distinguishing the castrated animal from a normal one. By injecting fractions of a lipid extract of bull testes into rats and guinea pigs the authors not only prevented the development of the castration effects by injecting immediately after castration, but also were able to eliminate castration effects that had been present for some mos. The spermatozoön motility test (guinea pig), the electric ejaculation test (guinea pig), the prostate test (rat), and the seminal vesicle test (rat), all proved that the extracts injected were able to substitute for the internal secretion of the testicle. The authors found no castration change that failed to respond to the injections. —*Authors' summary and conclusions.*

15875. **MORTIMER, BERNARD, and A. C. IVY. VII. Studies on the pancreas. An attempt to repeat the Mellanby procedure for the isolation and purification of secretin.** *Amer. Jour. Physiol.* 91(1): 220-224. 1929.—The isolation of secretin as described by Mellanby proved to be unsatisfactory in the hands of the authors because of the unreliability or lack of uniformity of results with the "bile salt" precipitation procedure. In default of more exact knowledge regarding the conditions governing the adsorption of secretin by "bile acids" they were unable to predict a yield with certainty.—*Authors' summary.*

15876. **MYERS, WALTER K. The effect of bilateral ovariectomy in cats upon sensitivity to insulin.** *Amer. Jour. Physiol.* 89(3): 610-617. 1929.—Bilateral ovariectomy in 4 cats caused an immediate increase in sensitivity to insulin and was followed by a marked increase in weight. There was a gradual recovery of resistance to insulin to such an extent that the sensitivity was subsequently diminished in comparison with that of the intact animal. Blood sugar levels and the general reaction to insulin did not coincide from time to time. This would suggest that insulin shock and hypoglycemia are separate and distinct manifestations resulting from the injection of insulin. There seems to be an exaggeration of their independence following the recovery of the animal from the immediate effects of ovariectomy.

15877. **OLDBERG, ERIC. An attempt to auto-transplant the adrenal.** *Amer. Jour. Physiol.* 91(1): 275-283. 3 fig. 1929.—Attempts to auto-transplant the adrenal into the omentum and spleen were unsuccessful. The adrenal on a pedicle consisting of the anastomosing blood vessels of the kidney capsule functioned adequately to maintain life for relatively long periods of time in 4 of 15 dogs. Sectioning of the pedicle resulted in death from adrenal insufficiency in 3 dogs; in the 4th, the animal died on the 6th day due to a ruptured duodenal ulcer. It is pointed out that the rich blood supply that the adrenal receives normally is physiologically significant. The pseudo-transplanted adrenal on a pedicle does not readily develop a secondary, or a new blood supply, which is in contrast to such tissues as the skin, stomach, pancreas, intestine, etc.—*Author's summary.*

15878. **ORSÓS, EUGEN. Pseudohermaphroditismus und die Zwischenzellen.** *Deutsche Zeitschr. Chir.* 230 (3/5): 211-219. 6 fig. 1931.—In an otherwise intensely feminine woman, operation revealed the total absence of ovaries and uterus. Each groin contained a mobile structure the size of a nut, histological examination of which revealed an abundance of interstitial cells. The author concludes that these cells have no influence on the secondary sexual characteristics.

15879. **PARHON, C. I., et CONSTANCE PARHON-STÉFANESCO. Sur un nouveau syndrome hyperhypophysaire: le nanisme hyperhypophysaire.** *Rev. Belge Sci. Méd.* 2(4): 336-340. 1 fig. 1930.—A girl 16½ yrs. old, 138 cm. tall, showed some signs of thyroid deficiency; but basal metabolism and intelligence were normal. Sexual maturity had become established at the age of 11. The sella turcica was enlarged. The authors believe that the dwarfish stature and the early sexual maturity are due to excessive or precocious functioning of the anterior lobe of the hypophysis; they propose the name of "hyper-hypophysial nanism" for the syndrome.

15880. **PENCHARZ, RICHARD I., J. M. D. OLMSTED, and GEORG GIRAGOSSINTZ. The survival of rats after total and partial adrenalectomy and adrenal transplantation.** *Physiol. Zool.* 4(3): 501-514. 2 pl. 1931. —Complete adrenalectomy in 62 piebald rats caused acute "insufficiency" symptoms and death in every case. The longest survival was 18 days, the average 7-8 days. The only sure test of complete adrenalectomy is histological examination of the removed glands. Each gland must be removed intact. If even so small an amount of cortex as 5% of the original gland remains, the rat may survive indefinitely. We believe that the survival of adrenalectomized rats reported by many investigators is due to incomplete removal of the glands, not to accessories. In over 500 rats, only one was found with a definite accessory. The severity of deficiency symptoms is roughly inversely proportional to the amount of cortex left. Subsequent removal of fragments which had been sufficient to keep rats alive, although in a state of "chronic insufficiency," caused death. Successful transplants of cortical material have been made into the ovary in 5 cases. Removal of this ovary at a time when these rats had lived longer than the longest surviving completely adrenalectomized rat, and were still in excellent health, now resulted in acute "insufficiency" symptoms and death.—*Authors (courtesy Wistar Bibl. Serv.).*

15881. **PERUSSÉ, GEORGE LOUIS Jr., and JOSEF SAMUEL ROZEN. The effect of experimental hyper-**

thyroidism on the movements of the empty stomach. *Amer. Jour. Physiol.* 91(1): 291-297. 1929.—Dogs (5) were used throughout the investigation (9 mos.). Of the 5 animals originally used, 2 were again run on a much higher dosage after an interim of 5 mo., during which time they were used for other work. A small dosage of desiccated thyroid sufficient to produce the syndrome of hyperthyroidism in dogs causes an increase in the height of hunger contractions. There seem to be 2 effects produced by feeding desiccated thyroid: one in which a hunger producing constituent causes an increase in hunger and the other in which a toxic, depressant constituent may or may not overbalance the former, depending upon the degree of tolerance to the latter that the individual dog may develop; or, it may be that these are one and the same substance, its hunger effects depending upon the tolerance developed by the individual dog. In the 15 gm. dosage, the increase in hunger effect seems to overbalance the toxic effect although the same result might have been noted in the 5 gm. dogs had they been run long enough.

15882. **PTASZEK, L. Influence des hormones sexuelles sur le métabolisme basal. Essais expérimentaux chez les femelles.** *Compt. Rend. Soc. Biol.* 100(14): 1250-1252. 1929.—In ♂ and ♀ dogs there was an immediate drop in the basal metabolism following excision of the gonads, followed by a short period of increased basal metabolism, which was in turn superseded by a permanent lowered basal metabolism. In the ♀ the 2nd period was shorter, and the increase was not so great. The author attributes this to the relatively more important part played by the ♀ hormone, and the resultant inability of the rest of the endocrines to compensate for it.

15883. **QUIGLEY, J. P., and B. O. BARNES. Action of insulin on the motility of the gastro-intestinal tract. VI. Antagonistic action of posterior pituitary lobe preparations.** *Amer. Jour. Physiol.* 95(1): 7-12. 1930.—Insulin has been found to increase the motility of the empty stomach and of the small intestine and colon; this action is related to the development of hypoglycemia. A study of gastro-intestinal motility, therefore, offers an excellent method for investigating the antagonism between insulin and pituitary extract or its fractions. The balloon technique was used to follow the hyperactivity of the gut produced by insulin administration and to determine the antagonistic action of pituitary extracts. The pituitrin preparations were usually administered intravenously but intramuscular injections were found to yield similar results: 74 experiments which gave definite results were performed and 11 dogs were used. Pituitrin, vasopressin, oxytocin, vasopressin-oxytocin and infundin were all found to inhibit high or low spontaneous motility of the stomach, small intestine and colon. They likewise inhibit the hypermotile gut of insulinized animals. The inhibition begins in 15-20 sec. (before the blood sugar level is modified) acting probably through a direct paralysis of the motor mechanism of the gut. Modifications in carbohydrate metabolism are involved apparently in the later phase of the inhibition.

15884. **REISS, M. Studien über die Funktion der Nebennierenrinde.** *Endokrinologie* 6(5): 321-335. 1930.—The author shows that the life of an adrenalectomised animal can be lengthened by administration of a substance free from the blood pressure factor of the adrenal. The substance is remedial only if administered before the typical adrenalectomy symptoms appear. This limitation can not be directly due to a scant hormone supply from the cortex since injections of greater quantities of the extract are ineffective. The reactions once initiated by adrenalectomy are irreversible; the extract hinders the process only if administered in time.—*B. Cunningham.*

15885. **REISS, M. Studien über die Funktion der Nebennierenrinde.** *Endokrinologie* 6(6): 421-437. 1930.—The author confirms previous work which showed death following adrenalectomy is decerebrated cats and dogs. Death seemed to be due to respiratory failure. However, when artificial respiration was resorted to, death ensued after about the same interval. Injections of the cortex hormone prolonged life. The reserve alkali decreased after adrenalectomy, regardless of whether or not atificial respiration was used; the reserve was increased upon the hormone injection. The reduction of the alkali reserve seems to be due to a disturbance of metabolic materials for which the active factor has not as yet been found.—*B. Cunningham.*

15886. **RIDDLE, OSCAR, and JAROSLAV KŘÍŽENECKÝ. Studies on the physiology of reproduction in birds. XXVIII. Extirpation of thymus and bursa in pigeons with a consideration of the failure of thymectomy to reveal thymus function.** *Amer. Jour. Physiol.* 97(2): 343-352. 1931.—Thymus and bursa Fabricii were completely extirpated (thymobursectomy) from 17 common pigeons at a 1st operation performed about 42 days after hatching, or at a 2nd operation 3-4 wks. later; 15 brothers of the 7 operated ♂♂, and 26 sisters of the 10 operated ♀♀, served as control. Birds were reared to or beyond maturity (3-16 mos. after operation). That part of the body growth (14% of total) which occurred after the operation was not affected by the loss of these 2 organs. No clear and consistent difference was found in wt. of testes, ovaries, thyroid, liver or spleen in operated and control. No difference was observed in bone abnormalities, basal metabolism, health and appearance. The operation had no effect on the time or age at which the ♀♀ became sexually mature. The operated ♀♀ produced eggs (88) whose envelopes were quite normal, with only 1 exception; there were no soft-shelled eggs. These data and the more crucial data of Greenwood strongly question Stoli's report of soft-shelled eggs as a result of thymectomy in mature fowls, unless the particular race of fowl used really determines the result. The authors conclude that tissue with "thymic function" is probably widely scattered in the body of vertebrate animals generally. This condition is now rather more evident in birds than in other groups. In birds such tissue is probably regularly represented in the 2 thymi, the bursa Fabricii, the 2 postbranchial bodies, in the lymph glands and perhaps in other lymphoid organs; occasionally it is undoubtedly present in still other areas adjacent to the thymus. An extensive examination of the literature leads to the conclusion that theymectomy has almost everywhere and completely failed to reveal or to confirm those functions of the thymus which have been rather clearly indicated by various other methods of investigating this organ. The explanation of the failure of theymectomy to produce effects probably rests upon the existence and hyperplasia of other widely scattered tissue having thymic function. No result ever obtained from simple thymectomy is usable as evidence against the existence of an endocrine or other function of the thymus.—*Authors' summary.*

15887. **RING, GORDON C. Adrenalin and the metabolism of exercise.** *Amer. Jour. Physiol.* 97(2): 375-385. 1931.—The metabolism of rats [no. not stated] during rest and exercise on a specially devised treadmill has been determined. Small doses of adrenalin lowered the respiratory metabolism of fatigued rats in exercise. In 9 experiments on man (as in the rat) physiological amounts of adrenalin given after fatigue caused a lowering of the respiratory metabolism of exercise. Without previous fatigue, a similar amount of adrenalin increased the metabolism of exercise. The respiratory quotients were lowered by adrenalin.—*G. C. Ring.*

15888. **SACHS, WALTER BERNHARD. Umwandlungsversuche an kiementragenden Schwanzlurchen durch Schilddrüse und Schilddrüsenpräparate.** *Zool. Anzeiger* 88(11/12): 312-321. 1930.—The author failed in attempting to produce metamorphosis in *Proteus*, *Siren* and *Amphiuma* by feeding and injection experiments with thyroid gland and thyroid extracts.

15889. **SANDERS, GERTRUDE B. The survival period and blood pressures of adrenalectomized decerebrate cats.** *Proc. Soc. Exp. Biol. & Med.* 28(3): 288-

290. 1930.—For 27 out of the 30 operated cats, the average time of survival after adrenalectomy was 8½ hrs.; the longest time was 21½ hrs. Death was not due, as a rule, to respiratory failure as has been claimed by Vincent and Thompson. A slight (doubtfully significant) fall in blood pressure was sometimes observed after adrenalectomy.

15890. SCHLOTTHAUER, CARL F., and HAROLD D. CAYLOR. The effect of thyroidectomy and of certain diets on pregnant swine and their offspring. *Amer. Jour. Physiol.* 89(3): 601-609. 1929.—Of 12 pregnant sows on a balanced diet (Series 1), 10 were thyroidectomized and 8 of these received desiccated thyroids for 30-120 days. The sows treated for 60 days or more following thyroidectomy were not affected. Of 8 pregnant sows on a low protein, high carbohydrate diet (Series 2), 4 were thyroidectomized; 2 of the thyroidectomized and 2 of the normal sows were given thyroid extract to term. The results showed that the symptoms of thyroid deficiency in pregnant sows were influenced by the diet. Thyroidectomized animals on a balanced diet revealed signs of myxedema whereas those on a high carbohydrate, low protein diet did not develop the edema of myxedema and were underweight (allowance being made for pregnancy). The hair coat and thyroid gland of the offspring of thyroidectomized pregnant swine were not markedly different from the offspring of the control animals. The thyroid gland was not enlarged in offspring of thyroidectomized swine, although in each group there was considerable variation in the size of the glands.

15891. SCHWARZ, EUGEN. Pigmentierung, Form und Wachstum der Federn des Haushuhns in Abhängigkeit von der Thyreoideafunktion. *Zeitschr. Wiss. Biol. Abt. D, Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 123(1): 1-38. 12 fig. 1930.—No difference in the size of the thyroid in the sexes was found in 16-day embryos from the cross of Plymouth-Rock ♀♀ and Orloff-Kämpfer ♂♂ (factor K for slow feathering lies in X-chromosome for which ♀♀ are heterozygous, ♂♂ homozygous). In 2 hens without growth of the juvenile marginal plumage, degeneration of the thyroid was found substantiating a relation between thyroid function and speed of feathering. Half the thyroid of chickens (av. 3½ mo. old) was implanted into 2-5 day old chicks; most transplants underwent necrosis but residues remained. The excess thyroid had no action on increase in wt., and secondary and primary feathering. An increase in temp. in comparison to the controls (18th-23rd day) occurred. In the ♀ there was a darkening of the primary feathers; that of the secondaries was within limits of variability. In 1 hen and 1 cock successful thyroidectomy resulted in greatly inhibited growth, underweight, and extensive structural changes in the mature feathers. The feathers of the cock were very narrow and pointed in all regions. No change in pigment was observed; secondary sexual characteristics were well developed. The hen died 7 mos. after operation with signs of very pronounced anemia. The few new feathers (everywhere in body) were of intermediate type approaching the cock. The author differentiates between pigmentation and speed of feathering owing to the high metabolic rate, and feather forms: the thyroid first promotes pigmentation, then with larger quantities, oxidation of melanin and depigmentation occurs; increase of thyroid function speeds feathering; the development of feather form depends upon a cumulative action of thyroid and gonads, the action of the testis on the width and rounding of feathers being weakest, thyroid greater, ovary the greatest.

15892. SIEBERT, WALTER J., and ROBERT S. SMITH. The effect of various anterior pituitary preparations upon basal metabolism in partially thyroidectomized and in completely thyroidectomized guinea pigs. *Amer. Jour. Physiol.* 95(2): 396-402. 1930.—In an investigation of the reasons for the different effects of various anterior pituitary preparations, 24 ♂ guinea pigs, weighing between 350 and 500 gm., were used. Ten of these were as completely thyroidectomized as possible; 4 of these 10 were then given daily injections of 1 cc. of the acid extract of anterior pituitary substance, and 4 others were given 5 grain Armour anterior pituitary tablets by mouth daily; the remaining 2 of these 10 guinea pigs were used as completely thyroidectomized controls, to which no pituitary preparations were administered. Ten other guinea pigs were partially thyroidectomized, 1⅔ to 1½ lobes of the thyroid having been removed previous to the daily subcutaneous injection of 1 cc. of the acid anterior pituitary extract to 4 animals and the feeding of 5 grain Armour's anterior pituitary pills to 4 others. The remaining 2 of these 10 were used as partially thyroidectomized controls to which no anterior pituitary preparations were administered. Four guinea pigs were used as normal control animals. The basal metabolism determinations were then made on each of the 24 animals every 4th day with the Haldane open circuit respiratory calorimeter. Each observation consisted of a 2-hr. period on this apparatus. The animals were starved for a period of 24 hrs. before the determinations were made. The injections and feedings of the anterior pituitary preparations were made previous to the starvation period. The experiments were continued for 28 days after the beginning of the administration of the anterior pituitary preparations. The results were: (1) for Armour anterior pituitary tablets, a marked rise in basal metabolism in partially and incompletely thyroidectomized as well as normal guinea pigs, being thus independent of thyroid changes; (2) for acid extract of cattle anterior pituitary glands a marked and rapid rise in basal metabolism in normal guinea pigs, in partially thyroidectomized guinea pigs, a slight but definite rise in basal metabolism, and in completely thyroidectomized guinea pigs, no change at all in basal metabolism, the effects being apparently entirely dependent on hypertrophic changes produced by the pituitary extract in the thyroid.

15893. SPAUL, A. W., and W. W. MYDDLETON. Biological and chemical studies of extracts of the anterior lobe pituitary. *Jour. Exp. Biol.* 8(1): 30-43. 1931.—A buff colored precipitate is obtained by the addition of N/20 I solution to dilute acetic acid extracts of fresh anterior lobe substance. Similar acetic acid extracts of tissues and extracts of the anterior lobe prepared with other extracting media do not give the same precipitate with I. The precipitate indicates the presence and gives an approximate measure of the metamorphic factor in fresh gland extracts of the anterior lobe. Dilute acetic acid extracts of the precipitates after removal of the I with alcohol are biologically active and characterised by their phosphate content. Similar extracts of the posterior lobe give an I precipitate but the phosphate content is much lower than that of the anterior lobe precipitate. The I in these precipitates is adsorbed or loosely combined. The biological activity of anterior lobe extracts varies with the time of extraction and the concentration of the extracts. Its resistance to temperature, acid and alkali have been investigated. The metamorphic factor is slowly destroyed by pepsin and rapidly by trypsin.—*J. M. Robson.*

15894. SPAUL, E. A., and W. W. MYDDLETON. The phosphate content and the biological activity of the anterior lobe pituitary. *Jour. Exp. Biol.* 8(1): 44-54. 1931.—There is a direct quantitative relationship between the phosphate P precipitated by I solution from active extracts of the anterior pituitary lobe in dilute acetic acid and the metamorphic activity of the lobe. Substitution of the phosphate content of the I precipitate by other radicles results in the loss of activity. The active factor is insoluble in alcohol, chloroform and ether, which distinguishes it from Robertson's Tethelin. The melanophore stimulant is independent of the phosphate content. There is a small quantity of phosphate precipitated by I solution from posterior lobe extracts. —*J. M. Robson.*

15895. STEWART, G. N., and J. M. ROGOFF. Studies in adrenal insufficiency. IX. The influence of extracts of adrenal cortex (sheep and cattle) on the survival period of adrenalectomised dogs and cats. *Amer. Jour.*

Physiol. 91(1): 254-264. 1929.—In paper V. of this series proof was given that extracts of adrenal cortex from dogs (interrenalin) can prolong the period of survival of dogs after adrenalectomy beyond the maximum seen in control untreated animals. It was stated further that similar results were obtained in dogs by intravenous injection of cortical extracts from sheep's adrenals. The data on the influence of these extracts are given in the present paper. Subcutaneous administration of the extracts did not exert as favorable an influence as intravenous injection. Extracts prepared from the adrenal cortex of cattle in the manner recently described by Hartman and his co-workers and administered subcutaneously, as in their experiments, were found to have no influence on the survival period of adrenalectomised cats, as compared with the untreated controls. These extracts, injected intravenously into dogs, were not nearly so effective as the authors' own extracts. If they produced any definite effect at all, it was slight. Subcutaneous administration in dogs had no favorable influence upon the survival period. Accessories were found in about 6% of 121 cats operated on for removal of the adrenals. Ulcers in the stomach or duodenum of adrenalectomised dogs and cats are very common. Of 118 adrenalectomised dogs, 48 had 1 or more ulcers. Of 89 adrenalectomised cats, 29 had ulcers. Of 32 normal cats, only 1 had a gastric ulcer.—*Authors' summary.*

15896. STILL, EUGENE U., et al. Studies on the physiology of secretin. II. EUGENE U. STILL, and L. B. SHPINER. The effect of purified secretin on the blood sugar. III. JEAN la BARRE, and EUGENE U. STILL. Further studies on the effects of secretin on the blood sugar. *Amer. Jour. Physiol.* 91(2): 496-498; 649-653. 1930.—II. Purified preparations of secretin injected intravenously in 3 normal and 3 diabetic dogs, barbitalized or unanesthetized, did not alter the blood sugar. Secretin per se does not have insulin-like properties. Secretin does not stimulate the secretion of insulin from the pancreas. III. The experiments here summarized indicate that crude secretin may be prepared which is not hypotensive, possesses great potency as a pancreatic secretagogue and contains varying amounts of hypoglycemic substances. Crude secretin may be fractioned into one part which is only secretagogue and another which will lower the blood sugar. The hypoglycemic fraction from crude secretin is not hypotensive, is not insulin, and produces hypoglycemia by at least 2 known factors: (1) stimulation of secretion of insulin (most important); (2) effects of the preparation per se. Purified secretin has no effect on the blood sugar.

15897. TANIGUCHI, TORATOSHI. Experimentelle Studien über die Neotenie bei Amphibien. *Folia Anat. Japonica* 9(2): 81-90. 3 fig. 1931.—The author experimented on *Hynobius fuscus, Bufo vulgaris japonicus,* and *Rana japonica.* Metamorphosis was not retarded by feeding larvae with powdered thymus. Larvae fed with powdered beef thyroid and with the thyroideum of Sankyo & Co. showed a considerable acceleration of development and of metamorphosis. The 2nd preparation gave the stronger reaction, and was more effective on anuran larvae than on larvae of urodeles. Tadpoles kept at 10-0° C. died about 3 mos. before metamorphosis. Under the same conditions Hynobius larvae lived and retained their larval form for 2 years (partial neoteny); there was marked stagnation of colloid in their thyroid glands. In larvae fed with the thyroid preparation and kept at 5-0° C., no reaction of the thyroid gland was observable. It can be said, therefore, that low temperature is necessary to bring out neoteny by suspending the activity of the thyroid gland.—*Author (courtesy Wistar Bibl. Serv.).*

15898. TEEL, HAROLD M., and O. WATKINS. The effect of extracts containing the growth principle of the anterior hypophysis upon the blood chemistry of dogs. *Amer. Jour. Physiol.* 89(3): 662-685. 1929.—The blood of fasting dogs was analyzed just before and for a number of hrs. after the injection of growth promoting extracts of the anterior hypophysis of the ox. No significant changes were found in total P, preformed or total creatinine, uric acid or sugar. A drop in serum Ca following the injection was often but not always observed. Very slight changes in inorganic P sometimes occurred but the findings were not consistent. A marked drop in non-protein N, however, was always observed after the injection of an active extract (20-30%). The disappearance of some urea and amino acids from the blood following injection was also an almost constant finding, the amt. of drop being fairly well in keeping with the percentage composition of the blood, and not sufficient to account for more than 70% of the total drop in non-protein N. Control experiments showed that after 20 hrs. of fasting a level of non-protein N, urea and amino acids is reached in the blood. Pituitrin does not cause a disappearance from the blood of non-protein N, urea or amino acids. Neither does an extract of serum protein, nor an extract of anterior hypophysis which has been inactivated by boiling. These control experiments indicated that the disappearance of non-protein N, urea, and amino acids from the blood following the injections of active extracts is probably due to the effect of the growth principle of these extracts. The question arises as to whether this disappearance of non-protein N constituents of the blood may be attributed to increased excretion. It is impossible to draw any final conclusions, for the amts. of non-protein N and urea which disappear from the blood are too small to be traced in the urine. Experiments, however, in which the dog is deprived of water, thus cutting down on urine formation, still show appreciable drops in the non-protein N constituents of the blood after injection, and seem to furnish some evidence against increased excretion as the only explanation of the phenomena. Also the fact that the amino acids and the "undetermined N" portion of the blood decrease after injection seems to indicate that the effect is at least in part endogenous. The distribution between corpuscles and plasma of the non-protein N constituents of the blood is apparently not affected by the injection of active extracts of the anterior hypophysis of the ox. The disappearance from the blood of these constituents after injection is in general rather evenly distributed between corpuscles and plasma. Total analysis of the blood of 2 dogs made definitely acromegalic by daily injections of active extracts of anterior lobe, revealed no definite changes in the blood composition as compared with the control period before the injections. The results seem to supply some evidence that the growth promoting principle of the anterior hypophysis has an immediate effect upon the non-protein N constituents of the blood. This effect may be, at least in part, one of mobilization from the blood for building up new protoplasm.—*Authors' summary.*

15900. UHLENHUTH, EDUARD. Die Morphologie und Physiologie der Salamanderschilddrüse. V. Die Wirkung von anorganischem Jod auf die Schilddrüse des Tigersalamanders (A. tigrinum) und des amerikanischen gefleckten Salamanders (A. maculatum). *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 115(1/2): 184-236. 20 fig. 1929.—Thyroids of larvae of *Amblystoma* kept in I solutions and fed I crystals were studied by counting follicles, measuring whole gland, and examination of fresh unstained and stained glands. Small doses in a short time increase secretory cell activity (determined by increase in number and staining reaction of cell granules and by expulsion of numerous colloid vacuoles into follicular lumen) and eventually injure cells (shown by fading of cell boundaries and lack of intercellular pores and vacuoles) and inhibit emptying of colloid from follicles. Heightened secretion and lack of colloid expulsion lead to storage of colloid, swelling of follicles, fusion of follicles with resultant in-

crease in size of single follicles but decrease in total number. With continuation of I treatment, cell injury increases and cells are expelled into follicular lumen, but eventually cells adapt themselves to I so that they are no longer stimulated nor injured and normal activity (secretion and colloid expulsion) occurs. Large doses of I act similarly but cell injury occurs earlier and destruction of whole follicles is common. Finally adjustment occurs but it is less complete than after small doses. An interpretation of the action of I on the functional state of the thyroid and in Basedow's disease is outlined.—*A. E. Adams.*

15901. **UHLENHUTH, EDUARD, und CHARLES WINTER. Die Morphologie und Physiologie der Salamander-Schilddrüse. VI. Jodimplantation und ihre Wirkung auf die Schilddrüse.** *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 119: 516-530. 8 fig. 1929.—Following Blacher and Belkin, I crystals (.3-.7 mgm.) were implanted into body cavities of larvae of *Amblystoma tigrinum*. In a short time (earliest 9 days) larvae metamorphosed although only ½ as large as normal larvae at time of metamorphosis. This result is in marked contrast to the ineffectiveness of large amounts of I when fed to induce metamorphosis. After implantation, I is absorbed so speedily that there is no time for increased secretory activity of thyroid cells (as after I feeding), but thyroid cell injury and follicle destruction occurs resulting in decrease in follicle number and thyroid size. Since thyroid thus becomes incapacitated for removing excess I from the blood, all of it can work directly on the tissue of the animal (not known whether directly on body tissues in general or on special organs). Thus the thyroid in relation to metamorphosis sinks from the level of a maker of a specific hormone to that of a mere condenser and regulator of I.—*A. E. Adams.*

15905. **WEHEFRITZ, E., und E. GIERHAKE. Die Einwirkung heterologer Sexualhormone auf die Ausbildung der Keimdrüsen im Embryo.** *Arch. Gynäkol.* 142 (3) : 602-617. 12 fig. (3 col.) 1930.—Commercial ovarian hormone (menformon and progynon) was injected into developing chick embryos, some of which were examined and compared with untreated controls at various stages of growth, while 8 were allowed to hatch and live till the 10th month (sexual maturity). The chicks subjected to ♀ sexual hormone developed into ♂♂ in which the primary sexual differentiation was partially impeded from the embryonic period on, right testicle being rudimentary. This work tends to support the theory that hormonal action is sex-specific and that the sexual hormone is identical throughout the vertebrates. The fact that the ♀ hormone used inhibited the development of the ♂ gonad indicates antagonistic action in the development of the primary sexual organs.

15906. **WEHEFRITZ, E., und E. GIERHAKE. Über die Spezifität des weiblichen Sexualhormons.** *Zentralbl. Gynäkol.* 55 (1) : 16-21. 1931.—After introduction of menformon or progynon into the chick embryo atrophy of the testes and hen feathering occurred in the ♂. Extract of 10 mo. old Leghorn ovaries induced estrus in the mouse (number of animals and quantities not stated). From the seed anlagen of the sunflower an extract was obtained which produced the vaginal processes of estrus and enlargement of the uterus; mature follicles and corpora lutea were found in the ovaries. Extract of the remaining portions of the inflorescence had slight action.

Nervenheilk.* 120 (5/6) : 297-303. 1931.—In a patient with myxedema following partial thyroidectomy and roentgentherapy hypertonicity and pronounced hypersensitivity of the striated musculature appeared; the parathyroid had not been injured and the condition improved when thyroxin was administered.

15908. **WUNDER, W. Experimentelle Erzeugung des Hochzeitskleides beim Bitterling (Rhodeus amarus) durch Einspritzung von Hormonen.** *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 13 (4) : 696-708. 4 fig. (1 col.) 1931.—Hormones fed had no effect, those dissolved in aquarium water little, those injected a distinct action on the development of the mating coat of uncastrated ♂ sticklebacks and carp; manufactured products, particularly Extractum testiculi Henning (E.T.H.) were superior to home-made extract of bovine testis. Before, during, and after the period of spawning the same amount of hormone had different effects. In March 0.1 cc. of E.T.H. produced a full mating coat which appeared from ½-1 hr. after injection, remained 6 hrs., and then slowly decreased until the 10th hr. In April the same preparation was effective only 3-4 hrs., in June only 2-3 hrs. Such a varying behavior was also determined for other hormones. Various concentrations of the same preparation, given at the same time, had different actions. While 0.1 cc. E.T.H. acted 6-10 hrs., 0.075 cc. of the same preparation acted only 4-5 hrs.; 0.025 cc. acted also for 4.5 hrs., but did not have such a pronounced action. Female hormone had practically no effect; Prolan had a slight reaction before the spawning period, a very good effect during it, and a very poor one, or none, after. Epinephrine first produced brightening of the body for hrs., then reddening of the fins and finally darkening of the back, and then the complete development of the mating coat. Yohimbin very rapidly produced the most extreme mating coat, which lasted for days (up to 10). Probably yohimbin and the hormones acted by way of the sympathetic.—*Author's conclusions (transl.).*

LELAND C. WYMAN. Anaphylaxis in suprarenalectomized rats. VII. LELAND C. WYMAN, and CAROLINE TUM SUDEN. Note on the temperature regulation in suprarenalectomized rats.** *Amer. Jour. Physiol.* 89 (2) : 349-355; 356-361; 362-365. 1929.—V. In 9 out of 18, and 21 out of 30 doubly suprarenalectomized rats the non-protein and urea N of the blood was increased, the amount of increase tending to parallel the severity of the symptoms of suprarenal insufficiency. Such increases were not noted in 12 rats having either gross accessory cortical tissue or successful cortical transplants, in the absence of demonstrable chromaffin tissue. Following control blank operations, moderately high values for both substances were infrequently found during the 1st 2 wks. after operation, but these values were not so high as those observed in suprarenal insufficiency. Otherwise the values obtained were normal. The results indicate that the high values for non-protein and urea N of the blood after suprarenalectomy are associated with cortical insufficiency. It is suggested that this is further evidence for a function of the suprarenal cortex concerned with

the steady maintenance of certain bodily conditions.—VI. Of 25 doubly suprarenalectomized rats sensitized with horse serum 9 died from anaphylactic shock following the test dose, 5 had severe symptoms, 3 had moderate symptoms, and 8 had slight symptoms. No correlation was found between the presence or absence of gross accessory cortical tissue or the time of survival after operation and the susceptibility to anaphylactic shock. Normal rats (29) sensitized with horse serum had, following the test dose, no symptoms or only slight or moderate ones. Of 15 of these rats which were suprarenalectomized after the test injection 12 died of anaphylactic shock following a 2nd test dose injected after operation. Of 15 suprarenalectomized rats having autoplastic cortical transplants, and in some cases gross accessories as well, 6 died from anaphylactic shock following sensitization and the injection of a test dose of horse serum. An attempt to reduce the susceptibility of suprarenalectomized rats to anaphylactic shock by injection of adrenalin chloride solution gave suggestive though incomplete evidence of possible protection. It is concluded that suprarenalectomized rats are more susceptible than normal rats to anaphylactic shock, and that this increased susceptibility is not related to cortical insufficiency, but is consequent on the lack of medullary suprarenal tissue.—VII. After 2 hrs. in a moderately cold room 10 normal rats, 10 suprarenalectomized rats with autoplastic cortical transplants, and 5 suprarenalectomized rats having gross accessory cortical masses (with 2 exceptions) had similar slight variations in the rectal temp. All these had no marked external reactions to the cold and recovered their original normal temp. after 1 hr. at room temp. following exposure to cold. Rats having cortical insufficiency showed a fall in the rectal temp. after 2 hrs. in the cold room, showed more or less marked external reactions to the cold, and did not recover their original temp. in a warm room as soon as those having cortical tissue. The fall of rectal temp. upon exposure to cold and the inability to rapidly recover normal temp. is correlated with the degree of cortical insufficiency. It is concluded that the suprarenal cortex, as well as the medulla, is indirectly concerned with heat regulation.

15910. ZAWADOWSKY, M. Bisexual nature of the hen and experimental hermaphroditism in hens. *Biologia Generalis* 3(1/2): 129-170. 33 fig. 1927.—Completing and confirming his earlier operative and histological analysis, author concluded that every hen is potentially bisexual, not only right but the left gonad, the ovary as well produces tissues of testicular type and hormones influencing development of both ♂ and ♀ dependent characters. In young ovariotomized hens (10 cases, Brown Leghorn and hybrid) a smooth, oval or elongated rt. gonad was newly developed, practically identical with a testicle, its lobules composed of cords and of seminiferous tubules containing first stages of spermatogenesis and, rarely, mature sperms; among ♂ characters (large, red, erect comb, other head furnishings, voice, instincts and behavior of cock) appeared some ♀ characters (henny color and form of feathers, except for sickle feathers in tail). Whole complex resembles that of Seabright ♂. Left ovary implanted into body cavity or under skin of castrated cock (2 cases), or (1 case) regenerating in situ—along with rt. gonad—after incomplete removal, also produces, as in pathological cases, certain testicular tissue and male-type morphogenetic reactions. Probably left ovary ordinarily suppresses rt. gonad; but testis and ovary are not antagonistic, for testis was successfully established in castrated hen (4 cases), which sometimes regenerated ovary and became hermaphroditic. With ovary and testis secreting simultaneously they develop ♀ characters; with poorly developed ovary, asexual and ♂ characters. Masculinisin and feminisin, ♂ and ♀ morphohormones, are considered independent factors, not quantitative variations of one agent.—*J. W. MacArthur.*

15911. ZONDEK, BERNHARD. Hypophysenvorderlappen, HVH, und Placenta. Vergleichende quantitative Untersuchungen bei Mensch und Tier. *Zentralbl. Gynäkol* 55(1): 1-12. 1931.—H.V.H. contains 2 factors: A, producing follicular maturation and estrus; B, the luteinizing factor. The anterior lobe in 4 women contained 100-160 mouse units of A and 23-50 of B; that of 5 men contained 60-400 units A and 10-25 B; in carcinoma of the genitalia the hormone content in women was reduced about 75% but in instances of ovarian carcinoma it remained normal. In 5 hypophyses from pregnant and puerperal women little or no H.V.H. was found (transplantation experiments). On the other hand 1 unit A and B was found in 7 mgm. placenta in the 7th wk. of pregnancy, in 30 mgm. in the 11th, and in 200 mgm. at term: the absolute amts. were 1144, 1133 and 2900 units; these values can vary greatly. Since the hypophysis of the pregnant woman does not contain H.V.H. the assumption that the placenta is the source would seem obvious, but may be erroneous; the hypophysis might give up the hormone with increased rapidity. In cattle and swine an increase in H.V.H. is not found in placenta, urine, or blood; the anterior lobe contains about the same amts. as in the non-pregnant (in non-pregnant cattle 115 mouse units A and 74 B; in pregnant, 112 A and 60 B). The elephant, rat, mouse, and rabbit showed no increase in H.V.H. in urine or blood. The mare showed large amts. in the blood during the 1st 3 mos. but little in the urine. Its placenta is the same as that of swine.

15913. BISSONNETTE, THOMAS HUME. Studies on the sexual cycle in birds. V. Effects of white light of different intensities upon the testis activities of the European starling (Sturnus vulgaris). *Physiol. Zool.* 4(4): 542-574. 3 pl. 1931.—Under previously described uniform conditions, groups of starlings were subjected to light from 10-, 15-, 25-, 40-, 50-watt bulbs, and from 60-watt bulbs both with and without forced exercise, for equal periods nightly, from Nov. 9 to Jan. 27. Controls received equal daylight periods only. Samples from all groups were killed for study on Dec. 13, 23, and Jan. 27. All except controls underwent progressive testis changes, leading to complete spermatogenesis in 44 days, and some birds, from even the 10-watt-treated groups, passed the climax of spermatogenesis before 79 days, even under increasing daylight periods after Dec. 21, and regressed to various degrees; others did not. Rate of acceleration of germ-cell activity increased with light intensity from 10- to 25- (perhaps 40) watt bulbs; but above that no constant differences resulted. Fifty-watt bulbs

may be slightly more effective than 60's. Added exercise caused lag of onset of light-induced changes, both progressive and regressive. Data suggest a refractory period before appearance of light-induced effects, prolonged by added exercise, together with idiosyncrasies of susceptibility to regression. Juvenile birds gave neither so rapid nor so great increases in testis size and germ-cell activity as mature birds under like conditions. Total testis size, produced in midwinter by added electric light, sometimes surpasses the spring normal.—*Author* (*courtesy Wistar Bibl. Serv.*).

15914. **CREW, F. A. E., WM. C. MILLER, and JAS. ANDERSON. A brief note on the diagnosis of equine pregnancy by biological test.** *Vet. Jour.* [*London*] 87 (10): 450-457. 1931.—The test was conducted on ovariectomised mice. The urine was precipitated with sulphosalicylic acid, filtered and neutralized with $NaHCO_3$. Four mice were used in each test, being given a total of 1.2-3 cc. divided into 6 doses and given twice daily for 3 days. Vaginal smears were made on the 5th day after beginning the test. Positive results were determined by the presence of cornification of the vaginal epithelium. Since mares in oestrus showed the presence of the hormone in considerable quantities it was necessary to determine approximate amounts. No urine was considered positive unless it contained as much as 1,000 mouse units per liter. The mouse units increased as pregnancy progressed, one reading being 160,000 M.U. on the 187th day. Within 35 hrs. after foaling this animal's urine dropped to 800 units. A positive test could seldom be obtained before the 60th day. Out of 390 samples only 3 known errors were made and 2 of these occurred early in the work before quantitative estimations were made.—*I. E. Newsom.*

15915. **DOMM, L. V. A demonstration of equivalent potencies of right and left testis-like gonads in the ovariotomized fowl.** *Anat. Rec.* 49(3): 211-242. 3 pl. 1931.—An invariable sequel of sinistral ovariotomy has been hypertrophy of the rudimentary right gonad usually into a testis-like gonad. A similar gonad may develop simultaneously on the left, though is encountered more infrequently. Experiments were devised to demonstrate the reciprocal endocrine potencies of these gonads. Sinistrally ovariotomized individuals were subsequently dextrally ovariotomized and the left testis-like gonads allowed to develop. Birds with only left testis-like gonads develop masculine head furnishings. Variations in size occurred at different periods, interpreted as due to dependence upon size and condition of the gonad. Following operation, plumage became male, subsequently reverting to female. Some revealed secondary reversions to male followed by reversions to female, interpreted as due to fluctuations in production of female hormone which consequently ranged above and below the threshold of effectiveness. Two cases did not reveal initial reversion from male to female. All individuals revealed some masculine behavior, though none were known to tread. Spurs developed. Wolffian ducts revealed perceptible growth, sometimes becoming definitely convoluted. Oviducts varied in size. The largest occurred in birds reverting to female plumage, the smallest in those showing no such change. All modifications in birds revealing only left testis-like gonads coincide closely with those previously observed in sinistrally ovariotomized birds revealing only right testis-like gonads, and indicate equivalent endocrine potentialities of right and left testis-like gonads in ovariotomized fowl.—*Author* (*courtesy Wistar Bibl. Serv.*).

15920. **JARES, JOHN J. Failure to induce ovulation in the guinea-pig by intravenous injection of the urine of pregnancy.** *Anat. Rec.* 49(3): 185-189. 1931.—The normalcy and regularity of the oestrous cycles of adult, virgin guinea-pigs were observed by the usual external oestrous signs. In addition, the time of ovulation was defined quite exactly by employment of the vaginal wash technique during the oestrous period. Having thus established the time factor in the oestrous rhythms, intravenous injections of untreated urine from women at various stages of pregnancy were made during the dioestrous intervals, employing the ovulation date as a starting-point. Ovulation did not result from the injections in any animal, as evidenced by macroscopical and histological study of the ovaries removed 1 to 8 days after the injection of the urine. Moreover, no effect on the regularity, time relationship, or general characteristics of the oestrous cycle was observed from 1 to 4 oestrous cycles after the administration of the urine. These findings indicate a somewhat different mechanism for the release of ovulation in the spontaneously ovulating guinea-pig as compared to the non-spontaneously ovulating rabbit which readily ovulates when treated similarly with the urine of pregnancy.—*Author* (*courtesy Wistar Bibl. Serv.*).

Vét. et Zootech.* 83(Oct.): 545-548. 1931.—When urine of a pregnant woman was injected into a sexually immature ♂ mouse, it caused an appearance of puberty within a few days, characterised by an enormous development of the seminal vesicles, the testicles being little changed. In 300 trials this reaction never failed.

15922. **LOVELAND, GRACE, ESTHER E. MAURER, and FRANKLIN F. SNYDER. The diminution of the glycogen store of the rabbit's placenta during the last third of pregnancy.** *Anat. Rec.* 49(3): 265-274. 1 col. pl. 1931.—During the early part of pregnancy there is a considerable storage of glycogen in the maternal part of the placenta. In the present experiments the fate of the glycogen store during the latter part of pregnancy was found by histological examination (Best's carmine method) and controlled by chemical determinations. It was found by the histological method that roughly ¾ of the entire glycogen store disappears during the last third of pregnancy. The quantitative chemical determinations showed a decrease from 100 mgm. of glycogen per placenta at the 22nd day to less than 25 mgm. at term (32nd day).—*Authors* (*courtesy Wistar Bibl. Serv.*).

15923. **McCANCE, R. A., and A. WALTON. A case of double sex reversal in a hen.** *Jour. Heredity* 21(3): 130-131. 1 fig. 1930.—A normal light Sussex pullet after her 1st moult, which was prolonged, assumed ♂ plumage, spurs and behavior. One year later without an intervening moult she hatched 11 chicks from 12 eggs placed under her. Later in the year she began to lay and in the autumn reassumed ♀ plumage. Nothing abnormal was found macro- or microscopically in any of the organs.—*Authors' abstract.*

15924. **MOENCH, G. L. Studien zur Fertilität. 143p.** 24 fig. Ferdinand Enke: Stuttgart, 1931.—The monograph is a report of research work on the various phases and aspects of the subject of sterility. The author outlines the method of examination of sterile couples. He stresses the importance of a detailed anamnesis, of the determination of the breeding record, of the menstrual history, diet, amount of physical exercise and general health. He then takes up the physical examina-

tion of the woman and various gynecological lesions, transtubal insufflation, etc. The obscure causes of infertility, sexual incompatibility, vaginal acidity and psychic causes, which the author does not believe to be of great importance are next considered, followed by a short note on therapy. The second part of the paper deals with sterility in the man and the examination of the semen from the gross and microscopic standpoint and after discussing the interpretation of the number of the sperms and their motility the author describes in detail his researches on the morphology and biometrics of the spermatozoa and especially of the heads of these cells and the relation of these findings to the fertility of the particular individual. This part of the book is illustrated by many graphs and tables showing that abnormal morphology or biometrics (graphs from 300 or more measured sperm head lengths) always means disturbed spermatogenesis and therefore impaired fertility. In over 200 cases there has never been a disagreement between the microscopically obtained opinion as to the fertility of the man and the clinical outcome of the case. In conclusion the author says among other things: . . . . It seems possible, by means of exact and thorough examination of the semen, to determine not only the sterility or fertility of the man but also the degree of fertility. . . . . To judge from a relatively small number of cases, the morphology of the sperm cells and especially of the sperm heads gives the best and most dependable information as to the fertilizing power of these cells. Besides this the relative number of the ejaculated abnormal sperm heads seems to be a direct indicator for the fertility of the particular man. Thus no man with more than 19-20% abnormal sperm heads was of good fertility as judged from the breeding record, etc. . . . . The most important of the simple functions of the graphs was the coefficient of variability. In normal cases it was seldom more than 11.00. The upper physiological limit of this function seems to lie around 11.50.—*G. L. Moench.*

15925. NAESLUND, JOHN. Untersuchungen über den Übergang N-haltiger Stoffe vom Fötus auf die Mutter. *Acta Obstetr. et Gynacol. Scand.* 11 (3) : 293-350. 1931.—Determinations were made on blood specimens taken from the mother, some shortly before birth of the child, some during parturition, and some shortly after. On the child, determinations were made on blood from both the umbilical vein and the unbilical arteries, taken simultaneously with the specimens of the mother's blood at parturition. Tests of serum protein were made in 47 cases. In the mother's blood, the serum protein at the birth of the child is usually much higher than in the child's, particularly in cases in which labor has been brief, but energetic. (The mean value in the mother's blood was 8.2% as against 6.06% in the blood from the umbilical vein, and 6.19% from the umbilical arteries.) If labor has been protracted or the pains weak, possibly under the influence of deep narcosis, the serum protein in the mother's blood is not so high. Cases with nephropathy as a rule also show comparatively low values of serum protein in the blood of the mother at delivery. Neither these factors, nor asphyxia of the fetus appear to influence the protein content in the blood of the fetus, which is more constant than that of the mother. In the mother's blood, the water content of the serum (10 cases) is much lower (mean value 89.8%) than in that of the fetus (mean value for blood from umbilical vein 92.1%, from umbilical arteries, 91.9%). Evidently the values for the water and protein content of the serum of the same blood specimen are closely correlated, so that if the water content is low, the protein concentration will be correspondingly high, and vice versa. These variations in the protein content of the serum are therefore probably the result of changes on the water content of the blood. The plasma fibrinogen in the mother's blood at delivery (21 cases) is much higher (mean value 0.34%) than in the child's, in whom the values remain around 0.09% in both umbilical vein and umbilical artery blood, regardless of whether the fibrinogen content in the mother's blood rises or falls. The changes in the fibrinogen content of the blood plasma appear to have no relation to the changes in the concentration of the serum protein in the corresponding tests.

15926. PARKES, A. S. The reproductive processes of certain mammals. Part I. The oestrous cycle of the Chinese hamster (Cricetulus griseus). *Proc. Roy. Soc. [London]* B 108 (755) : 138-147. 3 pl., 3 fig. 1931.—Specimens failed to breed under laboratory conditions; this could not be traced to any abnormality of the reproductive organs of either sex. About half the females possessed perfectly normal reproductive organs (the remainder showed various degrees of fatty degeneration of the ovaries), and underwent a succession of short oestrous cycles similar to that of the mouse. The average length of the cycle was 4.3 days. A summary of the changes occurring in the ovaries, vagina and uterus is given in table 3. The average number of maturing follicles was 8, so that the size of litter is presumably similar to that of the mouse. Specimens collected in the field show a number of extraordinary bodies in the uterine wall. These bodies are obviously glandular in nature, and would appear to be true myometrial glands. Since they were not found in the laboratory specimens, they would seem to develop during some phase of the fertile cycle.—*Author's summary.*

15927. PENCHARZ, R. I., and J. A. LONG. The effect of hypophysectomy on gestation in the rat. *Science* 74 (1912) : 206. 1931.—In 43 pregnant rats complete removal of anterior and posterior lobes was followed by death at the end of a prolonged pregnancy, unless, as in 1 case, the mother's life was saved by removal of the fetuses from the uterus.

15928. PLACE, FRANCIS. Illustrations and proofs of the principles of population. Being the first work on population in the English language recommending birth control. Now exactly reproduced. With an introduction demonstrating Francis Place as the founder of the modern birth control movement, together with unpublished letters of Place on birth control, Coleridge's criticisms of Malthus' views on birth control. Critical and textual notes by NORMAN E. HIMES. 63 + xv + 355p. Houghton Mifflin Co.: Boston [1931?]. Price $4.50.

15929. REYNOLDS, SAMUEL R. M. Studies on the uterus. V. The influence of the ovary on the motility of the non-gravid uterus of the unanesthetized rabbit. *Amer. Jour. Physiol.* 97 (4) : 706-721. 1931.—From observations of 47 ♀ rabbits Reynolds concludes that marked uterine activity in the non-pregnant rabbit is associated with oestrus. Feeble activity has been twice seen in oestrus; moderate activity has been seen 7 times. Anoestrus is usually associated with only feeble activity, or none at all. The motility of the uterus of a rabbit deprived of its ovaries during oestrus becomes irregular and progressively less in 2-4 days. Complete quiescence eventually supervenes. The change has been demonstrated in the same rabbit, by obtaining records both before and after castration. Replacement therapy in castrate rabbits with Theelin and Estrogen, commercial water and lipid soluble oestrogenic extracts, may impart to the quiescent uterus activity such as usually occurs in the presence of the ovaries during oestrus. Hence the author concludes that the ovary of the non-pregnant rabbit normally exerts a profound effect upon the motility of the uterus. Occasional irregularities in uterine motility seen during oestrus indicate that certain unknown extra-ovarian influences sometimes modify or completely annul the effect of the ovary on the motility of the uterus. The minimal effective dose of Theelin as administered was less than 2 rat units per kgm. body wt. in recently castrated rabbits. In rabbits ovariectomized for 3 weeks, 20 rat units per kgm. is the minimal effective dose.

15930. REYNOLDS, SAMUEL R. M., [et al.] Studies on the uterus. VI. SAMUEL R. M. REYNOLDS. The effect of oestrin on the uterine fistula during pseudopregnancy. VII. GEORGE L. WEINSTEIN, SAMUEL R. M. REYNOLDS, and MAURICE H. FRIEDMAN.

Anaphylactic response of the non-gravid uterus of the unanesthetized rabbit. *Amer. Jour. Physiol.* 98(2): 230-236; 237-243. 1931.—VI. In experiments [apparently on 10 rabbits] a difference in threshold of the uterus to the action of Theelin on uterine motility was found in the first few days of pseudopregnancy. The initial cessation of motility may be overcome with small amounts of Theelin. After 4 days this was impossible with large amounts, whether given subcutaneously, intravenously, or by both methods over a period of 2-4 days. An acceleration in the return to activity following pseudopregnancy was not possible with the amounts employed. The effect of oestrin apparently is definitely inhibited after the first few days of pseudopregnancy, as regards its action on uterine motility. VIII. The uterine fistula preparation affords an adequate means whereby anaphylactic shock may be recorded in the unanesthetized rabbit. In 11 rabbits sensitized after parturition the normal type of uterine activity was retained, and the uterus responded with a marked tetanus in anaphylactic shock; 6 rabbits sensitized in early pregnancy did not show normal post-partum uterine activity. The data suggest that sensitization during early pregnancy is not easily accomplished. A marked difference exists in the latent period of the uterine response to pituitrin and to the shock dose of serum in the sensitized animal.

Gynäkol.* 136(2): 397-406. 1929.—Blood Ca may slightly increase before menstruation but is normal during the period. Inorganic P remains unchanged. Chloride and K show some decline and Na a marked decrease during menstruation. In primary and secondary amenorrhea, presumably due to ovarian hypofunction, the inorganic content of the blood is normal. During the climacteric the chloride shows a tendency to decline, but Ca, K, Na and inorganic P are within the normal range.—*E. W. McHenry.*

15934. **[SERGIEVSKIĬ, M. V., and I. R. BAKHROMEEV.] СЕРГИЕВСКИЙ, М. В. и И. Р. БАХРОМЕЕВ. О действии секрета предстательной железы на сперматозоиды. Влияние раздражения N. N. Hypogastrici на активную реакцию предстательного секрета. [The action of the prostate gland secretion on spermatozoa. Effect of stimulation of N. N. Hypogastrici on the active reaction of the prostate secretion.]** [German summary.] Русский Физиологический Журнал имени И. М. Сеченева (*Russ. Jour. Physiol.*) 13(1): 115-127. 1930.—The authors claim that no investigators (except those of Mislabskiĭ's school) have used a pure secretion of the prostate gland, since they obtained the secretion either according to Fürbringer or by a pipette from the cut prostate. In the first case a mixture of secretions of many glands of the urogenital tract is obtained. In the second case the admixture of blood can not be prevented. The prostate gland secretion obtained by the Mislabskiĭ-Borman method by the stimulation of the n. n. hypogastrici has none of these admixtures. The pH of the secretion has been variable. Continuous stimulation of the n. n. hypogastrici or the introduction of pilocarpine produces, instead of the original neutral secretion (pH=7.0), a distinctly acid secretion (pH=2.5 or more acid). Each secretion, regardless of the pH, caused energetic movements of the spermatozoa. At pH 6.0-2.8 the spermatozoa after a while begin to stick to each other, their movement disappearing slowly. It seems that activation of spermatozoan movement by the prostate secretion depends on some specific substance but not on the pH. Using Hess' viscosimeter, the viscosity of the prostate secretion was found to be 1.1 at the beginning of the experiment and attained a value of 1.0 after a continuous stimulation of the gland.—*S. A. Corson.*

15935. **SHELESNYAK, MOSES C. The induction of pseudopregnancy in the rat by means of electrical stimulation.** *Anat. Rec.* 49(3): 179-183. 1 fig. 1931.—Pseudopregnancy was induced by electrical stimulation of the cervix. The method consists of inserting a copper electrode, connected to a small two-cell induction-coil circuit, at the opening of the cervix and administering a light electrical shock. The method produced a greater percentage of cases of pseudopregnancy than other previously reported mechanical means. The controls were uniformly negative. A definite correlation between the frequency of occurrence of pseudopregnancy and the phase of oestrous cycle at which the animals are stimulated has been observed.—*Author (courtesy Wistar Bibl. Serv.).*

15937. **SIMMS, HENRY S. Studies in milk secretion. The influence of proteins on the distribution of salts between blood and milk.** *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 50-54. 1931.—Since the calculated osmotic pressures of cow blood plasma and of milk are the same, the udder membrane is freely permeable to water. Na is more concentrated in blood serum than in milk, while K, Mg, and Ca are more concentrated in milk; samples of milk and serum dialyzed against each other maintained this relation. Proof that equilibrium had been established was obtained by removing the salts from samples of serum and milk. To the resulting solution of serum proteins the salts of milk were added and to the solution of milk proteins the salts of serum were added. When these solutions were dialyzed against each other the salts returned to the other side of the membrane so that the final solutions were identical with those from the first dialysis, showing that the distribution of inorganic cations between blood and milk is determined by the proteins.—*Author's summary.*

15938. **SPENGLER, J. J. The fecundity of native- and foreign-born women in New England.** Pamphlet series vol. 2, no. 1. ix+63p. The Brookings Institution: Washington, 1930. Pr. 50 cents.

15939. **SVENNINGSEN, O. K. Einige Beobachtungen zur Erleuterung der Aetiologie der Linea fusca.** *Acta Obstetr. et Gynecol. Scand.* 11(3): 351-358. 8 fig. 1931. —It had previously been shown by Wernøe that skin dystrophies during pregnancy are produced under hormone influence such as all the tissues of the body are subject to, while the location is dependent on the affected innervation area. The author examined 73 previously laparotomized, pregnant women, and in 15 of these he found outside the scar a narrower, less pigmented or entirely broken linea fusca. This was found practically only in patients in whom the wounds had healed by second intention. There is thus probably a causal relation between broken (unregenerated) nerve fibers and a break in the linea fusca. The latter may therefore be assumed to be a skin dystrophy of both nervous and hormone origin, arising through an axon reflex of the endocrine cells of the internal genitals.

15940. **UNTERBERGER, F. Experimentelle Untersuchungen über die Tätigkeit der Eierstöcke nach Uterusexstirpation.** *Zentralbl. Gynäkol.* 54(11): 655-657. 1930. —At 6 weeks of age hysterectomy was performed on 4 rabbits and 2 dogs. Ovaries of 2 rabbits were examined histologically a year later; they resembled those of the normal in all particulars. The other rabbits and

dogs copulated with the ♂, which never occurs in castrates. Hysterectomy thus does not interfere with complete development and incretory function of the ovaries.

15941. **WESTMAN, AXEL. Über die Zirkulationsverhältnisse in der Uterusschleimhaut nach Corpus luteum-Exstirpation.** *Zentralbl. Gynäkol.* 55(24): 1890-1896. 7 fig. 1931.—An India ink suspension was injected without pressure into the abdominal aorta in an unstated number of pregnant rabbits. In normal rabbits the mucosal vessels were filled and showed ink; about 15 hrs. after corpus luteum extirpation some of the vessels were empty, some partly filled, some filled, but never normal. In all cases the constriction occurred at the mucosa where the vessels passed through the musculature and was caused by contraction of the myometrium. Intrauterine death and abortion after corpus luteum extirpation was thus caused by deficient blood supply to the uterus and thus to the placenta. Other experiments on circulation at time of spontaneous parturition indicate that similar processes of deficient blood supply are in operation. The corpus luteum thus initiates mucosal proliferation at the beginning of pregnancy and keeping the musculature inactive, guarantees normal circulation. Its absence leads to labor, to abortion, or to intrauterine death of the fetus with resorption, according to the period at which it ceases to act.

15942. **WESTMAN, A., E. JORPES, und G. WIDSTRÖM. Untersuchungen über den Schleimhautzyklus in der Tuba uterina, seine hormonale Regulierung und die Bedeutung des Tubensekrets für die Vitalität der befruchteten Eier.** *Acta Obstetr. et Gynacol. Scand.* 11 (3): 279-292. 5 fig. 1931.—Previously Westman showed that fertilized ova present in the uterine tube degenerate shortly after castration, due supposedly to the circumstance that the ciliated cells of the tubal epithelium are not transformed into functioning secretory cells. This process of transformation is probably dependent on a hormone from the corpus luteum. In 5 experiments (apparently on rabbits), the corpora lutea were cauterized, without castration, 12 hrs. after coitus, i.e., after the ova had reached the tube. Section of the tubes 60 hrs. later showed the same effect as castration, i.e., no transformation from ciliated to secretory cells, and degeneration of ova. Ovarian extracts of various kinds produced uterine secretion in 10 of 17 castrated rabbits, and large doses permitted the preservation of the fertilized ova, results being better from extracts of the whole ovary than from extracts of corpus luteum alone. Ova which had been experimentally prevented from leaving the ampullar part of the tubes, in which there were never any secretory cells, degenerated even when there were functioning corpora lutea in the ovaries. These experiments show that the corpus luteum hormone elicits a cyclic transformation of the ciliated cells into secretory cells in the uterine tubes, and that the tubal secretion is of final significance for the vitality of the ova.

15943. **WIESNER, B. P., and L. MIRSKAIA. On the endocrine basis of mating in the mouse.** *Quart. Jour. Exp. Physiol.* 20(3): 273-279. 1930.—Mating was induced in oöphorectomised mice by injections of follicular juice; aqueous extracts of follicular juice did not induce mating. Eleven out of 20 oöphorectomised mice injected with cornifying extracts from pregnancy urine mated. Mating in these experiments is assumed to be an effect of the cornifying (α) factor conditioned by a higher threshold than cornification. The relation of the thresholds of cornification and mating can vary and this may explain mating during pregnancy.—*B. P. Wiesner.*

15944. **ARNDT, GEORG. Über die Abhängigkeit des Stereoeffektes von der Geschwindigkeit der bewegten Marke.** *Zeitschr. Biol.* 90(6): 574-588. 4 fig. 1930.—If a movable mark oscillating in the plane of an immovable one is observed under conditions in which the sensitivity of one eye is rendered less than that of the other, the movable mark will appear to describe circles about the immovable one. This stereo-phenomenon of Pulfrich results from double images formed because of differences of perception time between the two eyes under the conditions mentioned. The experimental apparatus is described in detail. The differences in perception time were measured at velocities of from 2.2 to 400 angular minutes per sec. At the limit of motion perception the difference between the perception times of the two eyes amounted to $1900\sigma = 1.9$ second. Close agreement was obtained with the absolute values of perception time obtained by other means. It was found that for stereo-phenomena the moment of greatest import is the beginning of sensation, not the instant in which the latter reaches its maximum. Diversion of attention increases the stereo-effect.—*M. Monjé (transl. by P. A. Moody).*

15945. **FEIGENBAUM, ARYEH. Reflex transmission of stimuli from one eye to the other. The "dark-light test" following neurectomy.** *Arch. Ophthalmol.* 5(2): 261-268. 1931.—Dark-light tests on 3 patients with glaucoma before and after opticociliary neurectomy indicated that (1) the neurectomized eye reacts in a typical way, although the sensory connections with the center are cut. Thus one may assume a so-called axon reflex, i.e., a short reflex that does not pass through the center (intra-ocular vasomotor reflex of the uveal vessels). (2) The influence of the second eye probably likewise consists in a primitive reflex of this kind, i.e., an interocular vasomotor reflex transmission of stimuli. It is thus comprehensible that in absolute glaucoma with hypotonia (atrophy of the iris and secondary cataract) in which degeneration of the related nervous receptor organs has occurred, the stimulus evokes no response. The results of the dark-light test seem to point to the probability that in primary glaucoma the parallelism in reaction comes from a reciprocal influence of both eyes, and that the lowering of pressure in one eye, after the trephining of the other, must be ascribed to a vasomotor reflex. It is also easy to understand why a secondary glaucoma often does not show this parallelism, as it frequently arises not from vascular but from coarse mechanical lesions. Probably a certain predisposition of the vessels is a primary condition for the parallelism, somewhat as Schmidt regards the endothelium in patients with glaucoma. This predisposition would then be the hypothetic directing cause for the conformity in the reaction of eyes with primary glaucoma. In general, in the dark, eyes behave as if there were an irritation of the cervical sympathetic (dilatation of the pupil, a rise in tension) while the effect of light (contraction of the pupil, a fall in tension) suggests a parasympathetic stimulation. One should not speak of a causal connection between the width of the pupil and ocular tension, but rather of a correlation.

15946. **FELDERMAN, LEON, and JOHN MILNES DYSON. Tinnitus aurium: amelioration by intraspinal injections of glucose.** *Eye, Ear, Nose and Throat Monthly* 8(10): 439-442. 1929.—Tinnitus aurium for which no organic cause exists is generally due to increased or fluctuating intralabrinthine endolymphatic pressure. Increasing the cerebro-spinal fluid osmotic tension by the

injection of glucose solution ameliorated tinnitus aurium in 60% of cases. This was done apparently by reducing endolymphatic pressure.—*From authors' summary.*

15947. **FLEISCHER, ERNEST. Die Erscheinung der Farbtöne. Erkenntnis-theoretische Abhandlung.** 43p. Schwabe und Co.: Basel, 1929.—The author states that the Helmholtz theory of color vision is the precursor of his own. The assumption of differing sensitiveness to 3 different wave-lengths is common to both and Fleischer's illustrative figures are almost the same as those long in use for explaining the Young-Helmholtz theory. There are two important differences between the two theories. Fleischer's is quantitative. Perception of different colors is due to different electro-magnetic tensions set up in the retina and brain by light of different wave-lengths. The Young-Helmholtz theory is qualitative. While the latter assumes three types of retinal receptors, each type having a different function, Fleischer assumes retinal receptors of a single form each having three different nerve paths to the brain. In dichromates (red-green blind persons) there are only two of these paths; in monochromates (totally color blind) only one. The optic fibers are of a uniform nature and traversed by impulses which do not differ from one another in kind. The quantitative differentiation of stimuli takes place in the retina because all three fibers are not equally sensitive to the same wave lengths. When the nerve impulses reach the brain they set up different "tension-constellation" for the three different sets of wave lengths which the theory assumes. "These tension constellations are the only news which the brain receives from the outer world. They are without qualitative differences." The color tones are not, therefore, due to specific energies of nerves. The usual physical explanations are given for the blue of the sea, the color of sunlight, and of light from clear, thick ice. A section entitled, "the biological development of the optic nerve," discusses the possible order of development from an eye all of whose receptors respond alike to light of all wave lengths, to one which differentiates, first, the effects of long and short waves, and then those of intermediate lengths. It is evident that Fleischer's theory is self-consistent. The three-fiber assumption would account for color blindness, and quantitative differences might account for different colors and a color scale which would shift somewhat for different energies of impinging light. There seems to be no allowance for a difference in function of retinal rods and cones, nor for numerous other physiological facts.—*L. W. Cole.*

15948. **HARTLINE, H. KEFFER. The dark adaptation of the eye of Limulus, as manifested by its electric response to illumination.** *Jour. Gen. Physiol.* 13(3): 379-389. 1930.—Dark adaptation of the eye of *Limulus* is reflected in the behavior of the action potentials obtained upon stimulation by light. By determining the intensity of stimulus necessary to produce an electric response of a given magnitude (as to maximum action potential), at various times during dark adaptation, a quantitative analysis of the process may be made. This analysis is identical with that of Hecht for the dark adaptation of the human eye. This analysis indicates that dark adaptation in the *Limulus* eye may be represented by a chemical reaction of the second order—the recombination of products of photolysis to renew the depleted supply of photosensitive material. This is in complete accord with Hecht's conception of the photosensory process, and is in quantitative agreement with the results obtained by other methods in different animal forms. The experimental relation between strength of stimulus and magnitude of electric response reduces the assumption originally made by Hecht to account for the data on the human eye to an equivalent form; that the magnitude of electric response, provided it be sufficiently large, is directly proportional to the concentration of the photo-sensitive material in the sense organ.—*Author's summary.*

15949. **HOMANN, HEINRICH. Beiträge zur Physiologie der Spinnenaugen. III. Das Sehvermögen der Lycosiden.** *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 14(1): 40-67. 13 fig. 1931.—Methods published in 1928 were applied to the eyes of Lycosidae and Pisaura. Anatomically, the bilateralism of the lateral eyes in Lycosidae is peculiar. Arrangement and angles of the rhabdomes are measured with a vertical illuminator. The visual fields of the lateral eyes encircle the spider completely, overlapping very slightly. The visual fields of the main eyes overlap extensively within the field of the lateral eyes. The greatest angle formed by the rhabdomes is 1.5°. Lycosid eyes perceive motion, but not form. A stimulation of one or two rhabdomes is sufficient to make the spider react towards prey. Finding of ♀♀ occurs through motion stimulation of the eyes, but recognition of sex is attained by contact. Functional difference between main and lateral eyes was not determinable, but probably exists in accord with the structural differences.—*H. Homann (transl. by R. A. Muttkowski).*

15950. **IWATAKE, H. On the variation of the sense threshold caused by a change in the surrounding temperature.** [In Japanese, with English summary, p. 49.] *Jour. Oriental Med.* 14(5): 1931.—Believing that former methods of studying the elevation of the threshold of both heat and cold sensations ("phenomenon of adaptation") are defective because in them the source of heat must be removed when the sensibility is tested, Iwataki devised a method permitting uninterrupted examination of the change in sensibility. The surrounding air temp. was gradually or suddenly changed, while an adaptation of v. Frey's thermoesthesiometer was attached to the skin of the dorsal side of the right forearm. When the temp. lay between 15° and 50° C., the change in the warm threshold ranged from about 34 to 38°; that of the cold threshold from 30 to 35°. Sudden changes in the surrounding temp. caused the values of the thresholds to change in the manner of the ordinary adaptation curve (i.e., the logarithm curve). The course of the changes in the threshold values corresponding to the gradual changes in the temp. did not show a straight line, sometimes taking sudden leaps. The warm sense readily adapts itself to high temp. just as the cold sense does to low temp. The results show only the fatigue of the temp. sensory organs. The most remarkable results obtained show that the threshold temp. of the warm sense is lower than that of the skin under a high temp. and the threshold temp. of the cold sense is higher than that of skin under a low temp. The results indicate the existence of a steep gradient between the skin surface and the stratum of skin which includes the sensory nerve endings. The steepness of this gradient will be exaggerated by the pressure of thermoesthesiometer and the contact with a substance of better thermal conductivity. Results vary as the thermal conductivity of the surroundings varies.

15951. **KLEITMAN, N., et H. PIÉRON. De la variation du taux de sommation superficielle des impressions lumineuses en fonction de la nature de la lumière, de la région rétinienne excitée et de l'état d'adaptation.** [Variation in the norm of the superficial summation of luminous impressions, as a natural function of light, of the retinal region stimulated, and of the state of adaptation.] *Compt. Rend. Soc. Biol.* 100(14): 1174-1177. 1929.

[The nucleus tangentialis of the acoustic nerve and the oculomotor-vestibular reflex in teleostei.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 644-647. 1 fig. 1930.—In *Clupea pilchardus* impulses from the semicircular canals act reflexly on all ocular muscles. The nucleus tangentialis seems to constitute a peculiar apparatus for the oculomotor-vestibular reflex, taking part in the vestibular-motor reflex of the body and tail.—*M. Comel.*

15959. **BERGER, H. Über das Elektroenkephalogramm des Menschen. II.** *Jour. Psychol. u. Neurol.* 40(5/6): 160-179. 7 fig. 1930.—When non-polarizable AgCl needle electrodes are placed either in an epidural or subperiosteal position in human subjects an electroencephalogram regularly appears which shows variations 90 to 120 σ long and with an amplitude of .2 mv. On these are superimposed shorter ones 30 to 40 σ in length and .1 mv in height. These variations are independent of respiration and either the cerebral or cutaneous circulation. They accompany activity of the brain. The electroencephalogram shows periodic variations which correspond to the different degrees of mental attention. Mental work calls forth definite variations. In sleep the waves decrease in height. The author regards the larger variations, which he terms the Alpha waves, as an expression of the psychophysical processes taking place in the brain.—*H. Berger (transl. by W. J. Meek).*

15960. **BINGER, MELVIN W., FRED W. GAARDE, and J. MARKOWITZ. A study of bronchial reflexes in the guinea pig.** *Amer. Jour. Physiol.* 96(3): 647-656. 1931.—To study the possible physiologic mechanism for asthma (reflex contraction of the bronchioles) pulmonary reflexes were investigated in curarized, locally anesthetized guinea pigs (number not stated), these animals being used because susceptible to anaphylactic shock as evidenced by bronchospasm. The caliber of the bronchioles was measured by recording the movements of the lung through an intrapleural trocar, and by measuring variations in intratracheal pressure. It was found, in confirmation of the work of others, that the vagus nerve possessed both bronchoconstrictor and bronchodilator fibers. In addition, the observation was made that the bronchioles of a guinea pig were extraordinarily sensitive to such stimuli as clapping the hands, or stimulating the nose or the skin. Sectioning the vagi in the neck, paralyzing doses of atropine, or both, did not abolish these reflexes. Since the parasympathetic nerves had been eliminated, the authors conclude that both dilator and constrictor reflexes are carried by the sympathetic nerves to the bronchial muscles.

15961. **BOUMAN, H. D. Contribution à la connaissance de la marge d'excitation.** *Arch. Néerland. Physiol. Homme et des Animaux (Ser. 3c Arch. Néerland. Sci. Exactes et Nat.)* 14(2): 199-233. 3 fig. 1929.—The margin of stimulation of a muscle is the proportion between the intensity of the stimulus, required for the maximal and for the minimal contraction, this proportion being much greater in direct stimulation than in indirect.—*W. J. C. Verhaart.*

15962. **BRÜCKE, HANS. Die Regeneration des Halssympathicus nach Durchschneidung und die Wiederherstellung des Tonus seiner Erfolgsorgane.** *Pflüger's Arch. Ges. Physiol.* 226(2): 319-322. 1930.—In 12 cats the rate of regeneration after section and suture of the cervical sympathetic studied histologically was found to be about 1 mm. per day. The number of fibers distal to the point of section ultimately greatly exceeded the number proximal to it. In a large series of cats the functional capacity of its effectors was studied. For this purpose the reactions of the iris offered the most delicate quantitative index. The difference in diameter of the pupil on the operated and on the normal side was least when the normal pupil was about 6 mm. in diameter.

The difference between the pupils began to diminish long before regenerating fibers could have reached the superior cervical ganglion. Adrenalin injected intravenously under urethane narcosis yielded a dilatation on the operated side which never exceeded that on the normal side, although it was more prolonged. Bilateral extirpation of the superior cervical ganglion several days after unilateral section of the cervical sympathetic gave paralytic effects which were less intense on the side previously sectioned. Even after apparent recovery, the signs of paralysis reappeared under ether narcosis. —*G. P. McCouch.*

15965. **ECONOMO, CONSTANTIN von. Cytoarchitectony and progressive cerebration.** *Psychiatric Quart.* 1930 (1): (1-9). 9 pl. 1930.—The cortex of the human brain has three principal types of nerve cells: pyramidal, fusiform and small granular. In the isocortex, which includes about 11/12 of the cortex, these cells are arranged in 6 layers: (1) molecular, (2) external granular, (3) pyramidal, (4) internal granular, (5) internal pyramidal and (6) fusiform. The stimuli coming up to the cortex are received by the 4th layer; the 3rd and perhaps the 2nd serve the purpose of association; the 5th and 6th layers are purely efferent. The isocortex can be divided into fields of special function and structure depending upon the relative size and cellular content of these layers. 107 such fields are recognized. These fall into 5 main groups: (1) The agranular (motor) where the 5th layer is predominant. (2) The frontal with a special predominance of pyramidal cells. (3) The parietal with a predominance of the 2nd and 4th layers. (4) The polar with an increase in the granular layers. (5) The granular (sensory) with a special predominance of granular cells. The lower animals differ from man by the absence or pronounced poverty of development of those cortical fields that have to do with the higher intellectual functions. There is a gradual increase in the number and differentiation of these fields as one ascends the scale of animal life. This is also noticed in a comparison of the configurations of the brains of early man and that of the modern. This acquisition of new cerebral organs is called progressive cerebration. This process is subject to two laws. (1) The law of the irreversibility of evolutionary processes. (2) That of rectigradation and orthogenesis, or the inertia of development.—*W. Malamud.*

15966. **FISCHER, M. H. Reizversuche mit "Wärmestrahlung" am Zentralnervensystem.** *Zeitschr. Ges. Exp. Med.* 68(1/4): 139-144. 1929.—With a simple irradiation method local heat changes were induced in the sinus, auricles, ventricle and auriculo-ventricular boundary of isolated frog hearts. Radiation of the isolated sinus results in a marked auricular acceleration with decreased extent of contraction. The ventricle follows the auricle at first but later passes through stages of partial into complete block. The various degrees of block are believed to be related to the frequency changes. Occasionally transitory standstill occurs in auricles and ventricles at the moment of sinus irradiation, the significance of which is not clear. After longer sinus irradiation standstill appears first in the ventricle, then in the auricle and finally in the sinus. This is looked upon as a gradual decrease in sinus impulse formation due to heat injury. Local irradiation of the auricle or ventricle leads to a slowly spreading heat injury with decreased contraction in the parts concerned. Local irradiation of the A-V border leads to interference with conduction in the auriculo-ventricular funnel and consequent A-V block. During such a block funnel automatism may appear in the form of ventricular contractions and extra systole of the auricles. All these phenomena are completely and quickly reversible, when the irradiation is discontinued.—*M. H. Fischer (transl. by W. J. Meek).*

15967. **GAROFALO, A. Alcuni riflessi nel campo ostetrico-ginecologico. [Some obstetric-gynecologic reflexes.]** *Clin. Ostetrica* 32(12): 729-738. 1930.—Digital compression of the ovarian region by vaginal-abdominal pressure in 30 subjects produced the ovario-cardiac reflex (slowing of heart). Stimulation of erection of the nipple in 34 nulliparae and 50 puerperae produced the mammary-cardiac reflex (also a slowing).

15968. **GERARD, R. W., and J. WALLEN. Studies on nerve metabolism. V. Phosphates.** *Amer. Jour. Physiol.* 89(1): 108-120. 1 fig. 1929.—Fresh sciatics of winter *Rana pipiens* contain 27 mgm. % total soluble P, summer *R. pipiens* 39 mgm. %, spring *R. temporaria* 24 mgm. %, rabbit 25 mgm. %. For frog nerve this is present, roughly, ½ in inorganic form and ¼ each in acid labile and acid stable combination. For rabbit nerve, nearly ½ is in stable combination. Rest in O leads to a slight increase of combined P at expense of the inorganic. Rest in N causes breakdown of a good portion of both combined fractions so that the inorganic fraction constitutes 70% of the total, the others 15% each. Rest in O following N restores the initial ratios. Tetanization in O has an effect like asphyxia, giving 60% inorganic and 20% of each bound fraction. The total soluble P increases 5-10% during rest in O for several hrs. and about 15% in N or on stimulation. This may result from the breakdown of phosphatids. The results are considered in relation to carbohydrate metabolism and equilibration in nerve.—*R. W. Gerard.*

15969. **GROEBBELS, FRANZ. Die Lage- und Bewegungsreflexe der Vögel. XII. Die Wirkung von Läsionen verschiedener Hirnteile auf die Lage- und Bewegungsreflexe der Haustaube und ihre anatomisch-physiologische Analyse.** *Pflüger's Arch. Ges. Physiol.* 225(2/3): 340-356. 9 fig. 1930.—An experimental anatomical analysis in pigeons has shown that neck rotation after lesions of the medulla and the cervical spinal cord is due to internal arcuate and raphe fibers which cross to the motor cells of the cervical cord on the opposite side. The neck rotation and circus movements of more frontal lesions depend on fibers running between the mid-brain and thalamus and between the mid-brain and corpus striatum. The head nystagmus following a lesion of the optic lobes is opposite in its components to that following a labyrinth lesion. An isolated lesion of the accessory nucleus of the third nerve is followed by dilatation of the pupil and loss of reaction to light on the same side as the lesion. Injury of the ganglion isthmi reduces the light reaction in the contralateral pupil. Tonic impulses to the intrinsic muscles of the eye run in the tectobulbar tract. Tail spreading and elevation depend on the optic lobes and forebrain. Tr. tectocerebellaris also affects the posture of the tail. The disappearance of the postural tone in the limbs was found to be due to degeneration of the homolateral posterior columns. In ataxia the lateral cerebellar tracts are degenerated. A continuous landing reaction of the limbs is present during flight, without closure of the eyes, when both optic lobes are removed. After removal of the forebrain if the eyes are not closed the reaction of the limbs only occurs when the bird alights. After lesions of one posterior horn, posterior columns, or posterolateral column a supporting reaction appears. Other tracts than the rubrospinal must be concerned since this tract can degenerate completely without affecting this reaction.

15970. **GRUND G., und H. V. KURELLA. Die minimale Unterbrechungszeit.** *Deutsche Zeitschr. Nervenheilk.* 103(3/4): 113-129. 2 fig. 1928.—It was shown in an earlier paper that, under given conditions of interrupted direct-current-stimulation, degenerated muscle (instead of reacting with a tetanus as do normal) reac

only with an "initial twitch." If, however, the interval of closure following close upon the interval of open circuit is made longer, then the normal muscle also responds only with initial twitch (Engelmann et al.). In normal muscle it was further shown that, with current str. sufficient to elicit minimal contraction, the phenomenon of initial twitch then appeared when the preceding time of closure exceeded 8.67σ and the time of opening was below 1.33σ. Upon increasing time of rotation of interrupter, the time of closure required to call forth initial twitch no longer remained at 8.67σ but could be obtained still when as long as 90.3σ, the corresponding time of open circuit being at 17.7σ. For comparison observations were made on the same muscle (Extensor digitorum communis) in a case of neuritis of Nervus radialis showing reaction of complete degeneration. In this case normal rotation frequency and minimal current strength evoked no reaction at all. With increased current strength, however, the phenomenon of initial twitch at first could always be elicited, and finally there was again a marked lengthening of the required minimal intervening time of open circuit. With the duration of stimulus increased to 125σ and with current str. clearly more than required for minimal contraction, a marked lengthening of the intervening open circuit could be made without the initial twitch passing over into a tetanus. The set-up of apparatus is described and results in a case of right facialis showing reaction of complete degeneration following an antrotomy are added. An explanation of the phenomenon is suggested based upon Nernst's theory of electrical stimulation.—*C. D. Snyder.*

Méd.* [*Paris*] 103(12): 305-308. 1 fig. 1930.—The indicator is the psycho-galvanic reflex, which is provoked by a strong auditory (pistol shot) or mechanical (pinching) stimulus; the indifferent stimulus is a light. A diagram and explanation of the mechanism are given.

15972. KASAHARA, MICHIO, und SHIRO INAMATSU. Der Blinzel-reflex im Säuglingsalter. *Arch. Kinderheilk.* 92(3/4): 302-304. 1931.—Experiments on 2293 infants aged 2-12 mo. showed that the blinking reflex caused by stimulation of the optic nerve (finger approaching the eye) may be present during or somewhat before the 6th month but is not constant until 12 mos. The trigeminal blinking reflex (elicited by blowing on the face) is present from birth. The blinking defense reflex is not present until after infancy; none of the children examined made any defensive movements of head or body.

15973. KISSELEFF, M. Der Ringrhythmus an Nerv-Muskelpräparaten. *Pflüger's Arch. Ges. Physiol.* 226(1): 99-103. 3 fig. 1930.—Two or more nerve-muscle preparations (frog) were arranged in a closed circuit so that the nerve of one lay on the muscle of the next. A single shock applied to one nerve caused all the muscles to go into a tetanus. Simultaneous string galvanometer records from 2 muscles in the circuit confirm the hypothesis that impulses are passing round and round the circuit, each adjacent pair of preparations behaving as in the "secondary excitation" of Matteucci.—*W. A. H. Rushton.*

15974. KOCH, E. Elektrographische Untersuchungen über das Verhalten des Patellar-reflexes bei Langstreckenläufern. *Arbeitsphysiologie* 2(5): 409-416. 1930.—The patellar reflex of 5 and 8 km. runners was studied by means of an Einthoven string galvanometer. The reflex time was found to be of normal value and was longest with the tallest of the contestants. There was no appreciable difference in the reflex time before and after a race. In 12.5% after a 5 km. race, the patellar reflex was absent, and after an 8 km. run, it was missing in 60%. It remained negative longest in the victors.—*T. M. Carpenter.*

15975. LEVINE, MAURICE. Psychogalvanic reaction in painful stimuli in hypnotic and hysterical anesthesia. *Bull. Johns Hopkins Hosp.* 46(5): 331-339. 1930.—The psychogalvanic response was present (1) when a painful stimulus (needle prick), given during the hypnotic state without anesthesia (in a hysterical patient), produced overt responses and a report of perception of pain; (2) when a painful stimulus, given during the hypnotic state in an area of anesthesia produced by suggestion (in a hysterical patient), produced no overt responses and no report of perception of pain; (3) when a painful stimulus, given during the waking state to a patient with hysterical anesthesia, produced no overt responses and no report of the perception of pain; and (4) when the hallucination of a painful stimulus, suggested during the hynotic state, produced overt responses and the report of the perception of pain.—*Author's summary.*

15976. LUCCHI, GIUSEPPE, e GINO BENEDICTI. Valore e comportamento del riflesso solare in rapporto al riflesso oculocardiaco ed alle prove farmaco-dinamiche. *Gazz. Ospedali e Cliniche* 51(28): 883-888. 1930.—On the basis of tests in an unspecified number of cases (12 cited) the authors find that the solar reflex (manifested by slowing of pulsation and lowering of arterial pressure on compression of the epigastric region) exists, and may coexist with the oculocardiac reflex. It is, like the latter, subject to modification by various drugs, but it is often absent and not valuable in diagnosis.

15977. MAGNITZKY, A. N., und W. A. MUSHEJEW. Chronaxie und Parabiose. *Pflüger's Arch. Ges. Physiol.* 226(1): 1-10. 4 fig. 1930.—Parabiosis in nerve may include among its features hyperexcitability, narcosis and inhibition. This condition is produced by aniline, cocain hydrochloride, and phenol. In the poisoned region the rheobase continually increases and the chronaxie first decreases and later gets very long. In the "normal" part of the nerve rheobase and chronaxie exhibit changes which are usually rather less in magnitude. When the poison is removed there is a certain degree of recovery. The authors conclude that permeability changes underlie parabiosis.—*W. A. H. Rushton.*

15978. MICHOL, EDUARD. Fortgesetzte Untersuchungen zur Analyse der Wirkungsart sympathischer Nerven auf den quergestreiften Muskel. *Zeitschr. Biol.* 90 (4): 313-326. 18 fig. 1930.—To investigate the question whether the stimulation of sympathetic nerves makes motor nerve endings, previously made impermeable for excitation through fatigue, again permeable, two methods were used to abolish the passage of an excitation through the motor nerve endings, namely the use of curare and perfusion with a c.p. NaCl solution. In a curarised preparation an excitation of the nerve of whatever frequency had initially no effect on the muscle, but when by direct rhythmic stimulation of the muscle fatigue had been produced, stimulation of the motor nerve caused the same kind of restoration as is caused by stimulation of sympathetic nerves in a normal animal. The application of Boehm's purest curarine made the results still more clean cut. The stimulation of the sympathetic fibers themselves caused restoration of a curarised muscle fatigued by rhythmic direct stimulation. Therefore the method of stimulating the motor nerves of a curarised fatigued muscle is a new method of demonstrating sympathetic fibers for the muscle and motor nerves. The impermeability of the motor nerve endings after perfusion with the Ca-free NaCl solution was not bettered by stimulation of the sympathetic fibers. These facts are in favor of the view that sympathetic fibers act on a mechanism of the muscle itself.—*L. Asher.*

15979. MUSSEN, AUBREY T. The cerebellum. A new classification of the lobes based on their reactions to stimulation. *Arch. Neurol. & Psychiatry* 23(3): 411-459. 7 fig. 1930.—Confusion has existed because authorities have approached the study of the cerebellum from different angles and have adopted individual nomenclatures. Ontogenetic and phylogenetic studies have contributed to a changing classification. The finding that cerebellar lobes of the cat and monkey gave

definite responses to stimulation led to the necessity of a classification applicable to the human cerebellum as well. The plan adopted by the author was to present the lobes of the vermis, folium by folium, in a column, opposite to which the lobes of the hemispheres were placed. When uncertainty as to the grouping of a particular lobe arose because of an indefinite course of a hemispheral fissure, the position of the lobe was determined by the character of its reaction to stimulation. Localized reactions can be satisfactorily obtained only by the use of the stereotaxic instrument, of which there are only 3 forms in existence. The opinion of Mills and Weisenburg that the fundamental function of the cerebellum is synergia is in accord with stimulation results. A clearer idea of the grouping of the lobes of the cerebellum, founded on their functional activities as shown by stimulation may lead to a more ready appreciation of the early symptoms of cerebellar disease. There are 10 tables showing the generally accepted nomenclatures beginning with the B.N.A. of 1895, and also the author's general classification of the cerebellar lobes based on their electrical reactions, applicable to the cat, monkey and man; in addition, there are 7 diagrams.—*J. C. Michael.*

15980. **NOTO, GAETANO GIOVANNI. Un nuovo riflesso: il riflesso costo-pettorale. [On a new ribs-chest muscles reflex.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 508-510. 1930.—A reflex is elicited by striking the body of the 7th rib, and is given by contraction of the lower bundles of the musc. pectoralis major. It is adapted to reveal the existence of lesions of the segments D_1 to D_7 of the spinal cord. It is homolaterally weakened or absent in hemiplegia.—*M. Comel.*

15981. **POLJAK, S. Die zuführenden Bahnen des Vorderhirns und ihre Rindenbeziehungen auf Grund experimenteller Untersuchungen an Affen.** *Zeitschr. Ges. Neurol. u. Psychiat.* 125(1): 138-162. 9 fig. 1930.—The central portions of the somato-sensory, auditory and visual paths were interrupted in the brains of monkeys (*Macacus rhesus*) close to their subcortical origin and, after degeneration, were studied by Marchi's method. The origin, course, and cortical termination of each of the mentioned fiber systems were determined and their internal organizations studied. Conclusions were drawn with respect to the boundaries and location of the somato-sensory, auditory and visual projection cortex, and to the physiology and pathology of sensation, audition and vision. The exact projection of the retina (temporal crescent, perimacular and macular portions of the visual fields, horizontal meridian, vertical dividing line, points of fixation) upon the striate area was determined. (A detailed account with discussion of literature, and with conclusions concerning the physiology, pathology and diagnosis, accompanied by numerous illustrations and a bibliography appears in the course of this year as a monograph under the title "Main Afferent Fiber Systems of the Cerebral Cortex in Primates,"—University of California Press, Berkeley).—*S. Poljak.*

15982. **PORTA, VIRGINIO. Influenza della rachicentesi sulla termoregolazione, sul ricambio energetico e sulla glicemia. [Action of spinal puncture on thermoregulation, energy metabolism, and glycemia.]** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 48-52. 1930.—An increase of body temp. followed spinal puncture only when air was admitted. The pulmonary ventilation and the heat production are constantly increased, the latter from 20 to 70%. The R. Q. was in the majority of cases diminished, in the others unchanged. In most cases the glucose content of the blood was increased. Frequently the glycemia diminished afterwards. No constant relation was observed between glycemia and energy metabolism. The increase of heat production was independent of that of the body temperature. The author thinks that the mechanism depends upon a stimulation of the centers which control metabolism, the stimulus being given by the diminution of intracranial pressure.—*M. Comel.*

15983. **RADEMAKER, G. G. J., et S. HOOGERWERF. L'allure des muscles fléchisseurs et extenseurs du coude lors de la rigidité décérebrée.** *Arch. Néerland. Phys. Homme et Animaux, III C.* 14(4): 445-469. 19 fig. 1929.—In decerebrate rigidity not only the extensor- but also the flexormuscles of the arm show tetanic action currents. The stronger the rigidity, the stronger the action currents of extensors and flexors. Excitations increasing the rigidity cause an increase of the action currents of both sorts of muscles. After extirpation of the extensor muscles the increase of the action currents of the flexors still appears. Excitations which decrease the rigidity give first a decrease and then a disappearance of the action currents of the extensors. The action currents of the flexors decrease also but sometimes after the diminution and disappearance they reappear and become stronger than before; the limb then shows an "active" flexion. When the decerebrated animal lies absolutely quiet on one side, the action currents of the muscles soon disappear, usually in the first one or two hours. To maintain the tetanic contraction it is necessary that the animal be passively excited at intervals.—*G. G. J. Rademaker.*

15984. **RICHTER, CURT P., and MANLEY B. SHAW. Complete transections of the spinal cord at different levels: their effect on sweating.** *Arch. Neurol. & Psych.* 24(6): 1107-1116. 2 fig. 1930.—Complete transection of the spinal cord at different levels from C6 to L5 produced in 24 cats profound changes in the skin below the level of the lesion. These changes, which were similar to those found by Head and Riddoch in men with transections of the spinal cord, could be divided into 2 distinct stages. During the 1st stage, which lasted from 25-75 days, the skin was dry, while during the 2nd stage, which was more or less permanent, it became soft and moist and often was actually covered with visible sweat. By means of the electrical skin resistance method, it was possible to obtain a continuous picture of the onset, magnitude and duration of these changes throughout the 2 stages. During the 1st stage, when the skin was dry, the electrical resistance was high—much higher than would ever be suspected on the basis of palpation or inspection. Thus in all of the animals, it increased from a preoperative level of 40,000 to at least 2,000,000 ohms, while in some it rose to more than 25,000,000. During this stage, the galvanic skin reflex was absent. During the 2nd stage, when the skin was soft and moist and the sweat glands were obviously functioning again, the electrical resistance was as low or lower than before transection. At this time the galvanic skin reflex and spontaneous currents were present. The magnitude of the increase in the resistance of the skin was shown to depend on the level of the lesion with relation to the thoracico-lumbar outflow of the sympathetic nerves. A similar observation was made by Head and Riddoch regarding the distribution of areas of excessive sweating in men with transections of the spinal cord. By measuring the conductivity of the skin, it was possible to compare the effects produced on the sweat glands by transection of the spinal cord, sympathectomy and total nerve section, and in this way to throw more light on the question of what central and peripheral factors are involved in the control of the sweat glands. It is suggested that this method might be used in the future to study the localization and extent of injuries to the spinal cord in man.—*Authors' summary.*

15985. **RIZZOLO, ATTILIO. Localizzazione dei punti motori nella corteccia cerebrale della cavia. [The localisation of motor points in the cerebral cortex of the guinea pig.]** *Arch. Fisiol.* 29(1): 31-47. 4 fig. 1930.—In the cerebral cortex of the guinea pig motor regions determining muscular movements on the opposite side of the body can be located by the method of electrical stimulation. In each region a number of motor points can be located which when stimulated will elicit the same isolated muscular movement. These motor points differ with respect to excitability, one being the "optimum motor point" (that having the shortest chronaxie). The optimum motor point determining the extension and flexion movements of the anterior and posterior

limbs have the same chronaxie; the 4 motor points have the same excitability. The chronaxie of the optimum motor points of the anterior and posterior limbs is shorter than the chronaxie of the optimum motor points for the neck muscles, but longer than the chronaxie of the optimum motor points for the eyelids or pinna of the ear. The optimum motor point for the latter has a shorter chronaxie than the optimum motor point for the movement of the eyelids. Many facts substantiate the reality of the points located electrically in the cortex as truly motor: local application of strophanthin on a motor point diminishes the chronaxie of the grey matter, but does not affect the chronaxie of the white matter lying immediately underneath. Electrical stimulation of the caudate nucleus, the thalamus or the corpora quadrigemina evokes general muscular contractions of the entire animal. Clonic contractions evoked by local applications of absinthe on a motor point of the cerebral cortex disappear if during the contractions the grey matter is removed from the region. Loss of muscle tone and abnormalities in the behavior of a limb result if the grey matter is removed from a motor point determining its movement; the abnormalities become more evident if the ablation includes regions of other motor points determining movements of the same limb.—*M. Comel.*

15986. RIZZOLO, ATTILIO. Electrical stimulation of a lateral lobe of the cerebellum in relation to the excitation of the cerebral cortex. *Arch. Fisiol.* 29(2): 219-233. 1930.—In the dog, electrical stimulation of a lateral lobe of the cerebellum increases the excitability of the cerebral cortex. The effect of stimulation is always more marked on the side of the cortex contralateral to the cerebellar lobe electrically stimulated. Electrical stimulation of a lateral lobe of the cerebellum after a longitudinal division of the corpus callosum increases the excitability of the contralateral side of the cerebral cortex, but effects no change in the excitability of the homolateral side. It is inferred therefrom that in the dog each lateral lobe of the cerebellum is connected only with one side of the cerebral cortex, i.e., the contralateral side. The increased excitability effected on the side of the cerebral cortex homolateral to the lateral cerebellar lobe stimulated electrically—the corpus callosum remaining intact—cannot be attributed to diffusion of electrical lines of force from the cerebellar lobe, stimulation of the lateral cerebellar lobe after division of the corpus callosum longitudinally not effecting any change in the original excitability of the homolateral side of the cortex. The existence of a physiological relationship between a lateral lobe of the cerebellum and the side of the cerebral cortex with which it is connected is merely an assumption which the marked increase of excitability of the side of the cortex contralateral to the cerebellar lobe treated with electrical stimulation is not competent to settle. It is assumed that a lateral lobe of the cerebellum exerts a direct trophic influence on the cells of the contralateral side of the cerebral cortex, and an indirect one on the cells of the homolateral side of the cortex.—*M. Comel.*

15987. SCHNEIDER, KURT. Der Einfluss des Sympathicus auf die quergestreifte Muskulatur. *Pflüger's Arch. Ges. Physiol.* 225(1): 6-18. 3 fig. 1930.—Büttner and Heimbrecht have found that the registration of the contraction of the gastrocnemius muscle of a frog carried out 5 hrs. to 10 days after a unilateral sympathectomy shows on the side of the sympathetic denervation, in most cases, an increased contraction-rest compared with the intact side—80% on the average. This statement was re-tested by many experiments on summer- and winter-frogs. It was not possible to confirm it. The deviation found on the average after a unilateral sympathectomy did not overpass the differences found in numerous control experiments on intact animals. About 150 preliminary experiments were done in repeating and controlling the work of Büttner and Heimbrecht. The possible source of error is indicated. In further experiments the author registered the curve of contraction before and after the sympathectomy with the same muscle. It appeared that the height of the contraction and the contraction rest of the frog gastrocnemius registered immediately (3 min.) up to 1 hr. after the sympathectomy does not differ from that before the sympathetic denervation. In about 40% of cases a decrease of the contraction-rest below the original value during the first registration after sympathectomy could be observed. In control experiments it was proved that the effect observed was not caused by the sympathetic nerves. The normal muscle shows the same condition. The cause probably lies in a change of the mechanical condition of a muscle after a contraction, because the normal and the exsanguinated muscle shows the same conditions. Number of experiments not indicated; 20 experiments on exsanguinated frogs and ten on urethanized transfused frogs are tabulated.—*Author's summary (transl. by E. Polák).*

15988. SMYSLOW, G. G. Das digitoperoneale Phänomen und seine Beziehung zu den tiefen Gelenkreflexen, im speziellen zum Phänomen K. Mayers. *Deutsche Zeitschr. Nervenheilk.* 112(1/3): 124-139. 1930.—A study of the phenomenon produced by striking the toes, in which the foot is abducted. This is similar to the Mayer Phenomenon produced in a like manner in the hand. It is a true reflex of cerebral localization. The latent period was studied in adults, children and in various neurologic disorders. It appears in children at the time of disappearance of the Babinski reflex, and is of special significance in pyramidal lesions. Examinations were made under general and local anesthesia; the muscles involved are identified. Biogenetic and clinical significance are considered. Sphygmographic tracings were made. Bibliography included.—*A. E. Taft.*

15989. TRÄBITZSCH, W. Über die periphere Muskelerregbarkeit während Hell- und Dunkeladaptation. *Zeitschr. Psychol. u. Physiol. Sinnesorg. Abt. II. Zeitschr. Sinnesphysiol.* 61(2/3): 148-153. 1930.—The peripheral motor irritability was studied chronaximetrically on the M. flexor digitorum communis profundus in 9 persons with 19 experiments in the 1st series and an unstated number in a 2nd series by alternate illumination and darkening of both eyes. In 76 cases of adaptation to illumination (both series) there was shortening of chronaxie 31 times, lengthening 29, no change 16. In 82 adaptations to dark there was shortening 51 times, lengthening 18 and no change 13. Thus, in adaptation to light, changes in chronaxie were equally divided, a negative finding; in adaptation to dark there was a predominant shortening, showing an unequivocally specific influence. Similar changes could not be elicited otherwise even by strong acoustic stimuli.

15990. VERHAART, W. J. C. Some clinical and anatomical observations on the "Paraplegie en Flexion" and related motor disturbances. *K. Akad. van Wetenschappen Amsterdam, Proc. Sect. Sci.* 32(2): 961-972. 9 fig. 1929.—In cases of flexed lower limb 3 motor disturbances were seen. Severe degenerations of both frontal and central lobes caused the paralysis in flexion of the legs; degeneration of the 2 frontal lobes caused a permanent flexed position of the legs, with inability to go erect, but without paralysis of the muscles of the legs. These patients could stretch their legs actively. Two cases are described of hemiplegia in flexion, caused by degeneration of 1 hemisphere, by a paralytical process, particularly by a weakening down to the red nucleus. The conclusion was, that the tendency to flexion of the legs became manifest when the frontal lobes were out of function, then the typical human way of locomotion had disappeared, and the old flexed position of the legs became manifest again. This distribution of tonus remained, when a decerebration to the level of the red nucleus took place, which in animals, gives no disturbances of locomotion.—*W. J. C. Verhaart.*

15991. WASSILIEW, L. L., und M. R. MOGENDOWITSCH. Erregungssummation in einer alterierten Nervenstrecke. *Pflüger's Arch. Ges. Physiol.* 225(2/3): 389-402. 7 fig. 1930.—The authors conclude that the

Wedensky phenomenon (the single contraction following tetanic stimulation) is due to a summated stimulation process in the nerve fibre. This summation process is enhanced by the anode of a constant current, by hypertonia, and the cations of the alkaline earths. It is hindered by the cathode of a constant current, by hypotonia, by many cations such as Cu by the H-ion and by the OH-ion. Sodium ions have no marked influence. They form an intermediate group. The increased permeability of the colloid membrane of the nerve fibre and the "parabiotic" depression associated with this are unfavorable, whilst diminution in permeability creates favorable conditions for stimulus summation.—*H. Woollard.*

15992. **WEBER, HERMANN.** Beiträge zur Bewegungsphysiologie der Hippocampus-Arten. *Zeitschr. Wiss. Biol. Abt. C, Vergleich. Physiol.* 5(1) : 1-36. 21 fig. 1927.—There are 2 functional systems in the movements of the sea-horse, which are quite differently related to each other, in accordance with the situation in which the animal finds itself. The spinal animal (and also the motionless normal animal) shows only one, namely that of the tail movements concerned with clinging, which always take place mechanically in the same way, and always in response to the same stimuli. The higher system, which commonly conceals the other, consists of the fin movements and the steering movements of the tail, coordinated with them and with the functions of the labyrinths, under control of the brain rather than the cord. These tail movements influence to a considerable extent the direction of the forces exerted by the fins. Vertical and horizontal steering are controlled partly by the fins. The back fin advances the animal in the direction of its long body axis, the breast fin somewhat more obliquely upwards, in case of reverse undulation obliquely backwards and downwards. According to whether only the breast fins independently, or the back fin, or both together are employed, and also in accordance with the regulation of the position of the tail, the bodily posture and direction of movement are altered. Bodily posture, especially the position of the tail and fin movements, impulse and steering are closely interdependent and are grounded on the special structural relations which in turn condition equilibrium and posture.—*Author's conclusions (transl. by C. E. Kellogg).*

15993. **WORONZOW, D., N. JUDENITSCH, und P. MAKAROFF.** Zur Analyse der A. Fickschen "Lücken." *Pflüger's Arch. Ges. Physiol.* 226(1) : 113-137. 7 fig. 1930. Fick investigated the effect of different strengths and durations of current applied to a nerve upon the resulting muscular contraction. This work is repeated with the aid of string galvanometer records from nerve and muscle. Fick believed that when the contraction diminished with increase of current strength or duration, the impulse which started at the proximal electrode, was blocked in the neighborhood of the distal. The present authors reject this conclusion on the grounds of latent period measurements, and believe that the observed changes represent excitability variations localised at the electrodes. They conclude that excitation at the opening of a current can occur at the cathode as well as at the anode and that the local changes are an expression of the "accommodation" of Nernst.—*W. A. H. Rushton.*

15995. **BEHRENS, ALFRED und WALTER LAMPE.** Studien über die Beziehungen zwischen Blutdruck, Blutmenge und Herzgrösse. *Zeitschr. Ges. Exp. Med.* 61 (5/6) : 657-664. 4 fig. 1928.—Experiments on rabbits and dogs show that a lowering of the blood pressure consequent upon blood letting from an artery brings about a diminution in the size of the heart following a reduction of the blood volume and this can be restored again by the infusion of a colloidal solution. An artificial increase in the volume of the circulating blood can be induced by the infusion of a colloidal solution (normal saline, gum arabic). If a 20% gum solution, which takes up a considerable amount of water is used a plethora is produced by the infiltration of water from the tissues and this brings the total amount of fluid well above the estimated amount. The vascular system soon adapts itself to the changed blood volume. At the onset of the plethora a striking increase in blood pressure occurs and this pressure is the resultant of the strength of the heart beat, the blood volume and the amount of dilatation of the vessels. If the vessels are already full and dilated to a maximum extent there is a marked increase in blood pressure which is followed by a larger fall that results from actual injury to the animal. The same is true in cases in which the animal is damaged by a rapid overfilling of the blood vessels. In acute plethora also the heart is over distended. In slow infusion however both heart and blood pressure remain unchanged. When the blood pressure rises and there is an increase in the diastolic filling the tension also rises and the increased volume passing through the heart is in part responsible for the increased blood pressure.—*C. H. O'Donoghue.*

Internat. Physiol.* 3(1/3) : 272-309. 11 fig. 1929.—Continuation of a series of experiments on embryonic chick-heart transplants in vitro. The technique of transplantation was the usual one of tissue culture. Equilibrated salt solutions cause an increase in the frequency of the beat. The effects last 1 to 2 hrs. and are more evident when $CaCl_2$ and KCl are suitably increased. Similarly in isotonic solutions in which one of either salts is increased there is an increase of frequency which however leads early to complete arrest. Uranyl acetate acts in the same manner. The growth and the structure of the migrated myoblasts of cultures in normal salt solution are not different from those of cultures in plasma or tissue juice. The cultures are damaged by an increase of KCl and $CaCl_2$. KCl leads to a vacuolization of the cytoplasm. The cultures remain viable for a long time. Growth is not accelerated by $CaCl_2$. Uranyl acetate inhibits growth, causes formation of vacuoles, dissolution of the cytoplasm, alterations in the nucleus and finally death of the transplant.—*L. Braun (transl. by G. Bachmann).*

is described for the determination of the degree of elasticity of blood vessels. Observations are recorded on the deformation cycle of coronary and mesenteric arteries, produced either by simple extension and release or by repetition of uniform or progressively augmenting tensions. The extension curves of the coronary arteries show the following features: On release of tension, first contraction then generally slight dilatation with return to constant length. When tension is alternately applied and released, the tension and recoil curves bend sharply, with a slight terminal extension. In the case of the mesenteric arteries a sharp contraction follows the release of tension, with subsequent rapid elongation and return to constant length. Tension and release are followed by prolonged readjustments requiring hours for the attainment of normal calibre. The terminal phase is characterized by a decided elongation. Temperature changes, alterations in pH and acid deficiency influence the tension curves. The results are amplified and clarified with control histologic materials.—*Author's summary (transl. by H. E. Jordan)*.

16000. ENGELHART, E. Über humorale Übertragbarkeit der Herznervenwirkung. XIII. Die Vagusstoffverteilung auf Vorhof und Kammer bei Frosch und Säuger. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 721-727. 1930.—Experiments on the vagus substance and the distribution of it in the frog heart indicate that here the vagus has equal action on the atrium and ventricle, but that in the rabbit the vagus action is confined almost entirely to the atrium. The relatively small quantity of the substance in the ventricle is probably not due to direct action of the vagus nerve there but to transfer of the substance from the atrium.—*Author's summary (transl. by M. Dresbach)*.

16001. FLORKIN, MARCEL. Sur les substances qui provoquent des contractures musculaires. *Arch. Internat. Physiol.* 32(1): 114-116. 2 fig. 1930.—The contractions of a filament of fibrin from pigs' blood were ascertained in various media. Solutions of chloroform, lactic acid, $BaCl_2$, Ki, KCl and sodium glycocholate produced such contraction; acetylcholin hydrochlorid did not. Since acetylocholin hydrochlorid produces muscular contraction, it must do so by some other means than direct effect on fibrin.

16002. FREMONT-SMITH, FRANK, and HENRY S. FORBES. Intraocular and intracranial pressure. *Arch. Neurol. & Psychiatry* 18(4): 550-564. 9 fig. 1927.—Five groups of experiments were devised to study the relation between intraocular and intracranial pressure, and the dependence of both upon blood pressure. The cerebrospinal fluid and the aqueous humor are both in virtual equilibrium with blood plasma. However, they are more intimately related to the venous pressure, being only slightly affected by changes in the arterial pressure. The 1st group of experiments shows that when pressure is varied locally in either eye or cranium it is not directly transmitted from one to the other. The 2nd group shows a prompt and parallel rise in intracranial pressure in response to hydrostatic venous pressure. The 3rd group shows the effects of hypertonic solutions of NaCl, urea and glucose injected intraperitoneally or intravenously (glucose). Paralleling the rise in blood pressure there occurred a fall in intracranial and intraocular pressure. In the 4th group of experiments the osmotic pressure of the blood was lowered by injections of hypotonic solutions. The result was a rise in both ocular and cerebrospinal fluid pressures. The 5th group was designed to test the effects of CO_2, CO, epinephrine and fluorescein. These agents, with the exception of fluorescein, caused a parallel increase in both pressures.—*H. E. Pharmakol.* 139(5/6): 341-352. 3 fig. 1929.—Perfusion of cats' hearts by the Langendorff method with Ringer-Locke's solutions containing excess Ca or K, may bring about paradoxical changes in the functions of the cardiac nerves. When the solutions contain .04% $CaCl_2$ or .06% KCl stimulation of the vagus results in positive, and stimulation of the sympathetic in negative inotropic and chronotropic effects. Stronger concentrations of either salt destroy all nerve action. The disturbance in vagus function is only partial, for strong stimuli are still inhibitory. The disturbance in sympathetic function may be noted for all strengths of stimuli. The functional condition of the heart may determine the character of cardiac nerve response.—*W. J. Meek.*

16005. HAMM, LEE, and COBB PILCHER. Cerebral blood flow. II. The effect of intravenous injection of hypertonic and hypotonic solutions on the cardiac output and blood pressure. *Arch. Neurol. and Psych.* 24 (5): 907-912. 1930.—The cardiac output and blood pressure have been studied in [18] dogs before and after intravenous administration of hypertonic and hypotonic solutions. In most experiments the cardiac output was diminished after the injection of both types of solution, although individual variations occurred. The O consumption was usually increased and so was the O utilization by the injection of both hypotonic and hypertonic solutions. The mean blood pressure varied during the injection, but thereafter was increased slightly in all experiments. The average diminution found in cardiac output and the average increase in O consumption do not seem to be sufficiently great to account for the increase previously found in O utilization of the brain following injection of hypertonic and hypotonic solutions. This suggests that the latter changes are the result of direct effects of the solutions on the brain or its vessels.—*Authors' summary.*

16009. KISCH, FRANZ. Experimentelles zur Kreislaufwirkung endovenös einverleibter hypertonischer Lösungen. *Zeitschr. Ges. Exp. Med.* 56(1/2): 215-250. 13 fig. 1927.—The hemodynamic relationships, O utilization coefficient of the blood and the stimulus propagation in the heart were studied following the intravenous injection of hypertonic solutions of various reagents in varied concentrations into cats and dogs. The injection of 1 cc. per kgm. of a 40% glucose solution resulted in a hydremic plethora producing a prompt and lasting increase in the strength of heart beat and the minute volume of the heart with accompanying increase in the total circulation. Sugar solutions were more dependable and produced a greater effect than solutions of other substances. Following an initial increase the blood pressure dropped for a short period due to a decreased resistance in the arterial bed and in the capillaries as a result of the changed physico-chemical makeup of the blood. Then there was a lasting and often significant increase in the blood pressure occurring when the minute volume had reached its maximum since the dilator

factors cease to be effective when a complete osmotic equilibrium between the blood and the tissues has been established and the composition of the blood begins to return to normal. Although the heart rate is decreased by these injections the velocity of blood flow is increased due to the increased minute volume and increased blood pressure. The decreased O utilization coefficient also offers evidence for an increased blood flow. The electro-cardiogram on the introduction of 40% glucose confirms the assumption that as a result of the physico-chemical structure of the blood the impulse formation in the sinus node is made less effective since a change to atrio-ventricular rhythm can be concluded. In the case of other solutions specific factors dependent upon the reagent used may influence or delay the plethora and hemodynamic activity (e.g., the effect of K or Na on the heart muscle fibers). If the lesser circulation is not free or if the heart is incapable of driving an increased amount of blood through the periphery the intravenous injection of hypertonic solutions will have an injurious effect. Hence arise the clinical contra-indications in stasis through the lungs and in cardiac insufficiency. Edema resulting from a failure of the normal removal of fluids from an organ will not be aided by injections of concentrated sugar solutions since, following the plethora, fluid will again enter the tissue from the blood. Such injections should perhaps be helpful where there is danger of a sudden failure of the heart (e.g., acute edema of the lungs), when the circulation is chronically at low ebb, in spasms of the blood vessels where a prompt dilatation is desired and in tachycardia originating in the sinus node.—*H. M. Krueger.*

16010. LÁNCZOS, ANNA. Über die Wirkung des Vagusstoffes und Acetylcholins auf die isolierte Kammer des Froschherzens. *Pflüger's Arch. Ges. Physiol.* 225 (5/6): 710-720. 9 fig. 1930.—Both vagus substance and acetylcholin were found to exert a more powerful action on the ventricle of an intact frog's heart than on the isolated ventricle, indicating an indirect nervous influence conducted from the upper heart to the ventricle. Neither vagus substance nor acetylcholin were equally effective over all parts of the ventricle when detached; solutions of either substance which were effective on the entire ventricle were altogether inactive on the lower $\frac{2}{3}$. As the only apparent difference between the upper and lower portions consists in the difference in the number of nerve-endings, the fact seems to indicate a nervous point of attack for these substances. External application of acetylcholin to the isolated ventricle of the frog's heart produced a chronotropic action, while internal application had an inotropic effect.

Neurol. et Psychiatr.* 30 (1): 47-49. 1930.—Intense auditory stimulation increased arterial pressure, probably by first acting on the extracochlear fibers. Of the 11 subjects suffering from labyrinthic deafness 5 did not respond to auditory stimulus. In the others blood pressure was increased; in a case of hysterical deafness excitation of the deaf ear did not increase arterial pressure but excitation of the normal ear did.

16017. PILCHER, COBB. Cerebral blood flow. I. The effect of intravenous administration of hypertonic and hypotonic solutions on the volume flow of blood through the brain. *Arch. Neurol. & Psych.* 24 (5): 899-906. 1930.—The O content of arterial blood and of blood from the occipitovertebral sinuses, which drain a large amount of the blood flowing through the brain, has been studied [in 21 experiments on dogs] before and after the intravenous injection of 50% dextrose, or 30% NaCl and of distilled water. The blood, variable in its O content immediately after the injections, reached a point of stability within 30 min. and this was maintained for several hrs. After 30 min. there was rarely any significant change in arterial O content, but the O content of blood from the occipitovertebral sinus was invariably diminished markedly after the injection of both hypertonic and hypotonic solutions. The arteriovenous O difference (utilization of O) increased after injection of both types of solutions. It is thought that these results indicate probably a diminution in volume flow of blood through the brain after intravenous injection of both hypertonic and hypotonic solutions.—*Author's summary.*

16018. RASUMOW, N. P., and A. B. NIKOLSKAYA. The buffer function of the diaphragm and the cardio-abdomino-diaphragmatic syndrome. *Amer. Heart Jour.* 4 (5): 600-611. 8 fig. 1929.—The buffer function of the diaphragm with respect to the organs of the thorax, particularly the heart, is of the greatest biological importance. This function is realized both by the diaphragm and the abdominal press by way of the combined reflex as defined by Sherrington. The methods indicated by the authors make it possible to analyze the reflexes of the vegetative nervous system on the diaphragm; these reflexes fall in completely with the diaphragm buffer function theory. In pathological cases a perversion of the reflexes can be observed, occurring in cases of a tonus relaxation of the diaphragm and the abdominal press; the buffer function of both is then to a certain extent impaired. In such cases, when a sympathicotonic state in the domain of the cardio-vascular system or diseases of the cardiac muscle are present, a cardio-abdomino-diaphragmatic syndrome is usually developed, characterised by symptoms of cardiac insufficiency appearing after meals, after alterations in the position of the body, during sleep, under the influence of meteorological conditions, etc. Methods for investigating the intactness of the diaphragm and abdominal press buffer function are also given in the article under discussion.—*N. P. Rasumow.*

16019. REWJAKIN, S. W. Versuche über die Anwendung der Plethysmographie zum Studium des Einflusses von Sympathectomia lumbalis und Adrenalin auf den Kollateralkreislauf. *Zeitschr. Ges. Exp. Med.* 70 (5/6): 725-738. 5 fig. 1930.—The volume of the left hind extremity was measured by plethysmography in 22 dogs; 4 series of experiments were made: (1) The changes in the volume of the extremity were studied with the femoral artery temporarily occluded (5 experiments; primary decrease in volume of the extremity, gradual secondary increase, not reaching normal); with the femoral vein occluded (4 experiments; initial increase in volume, followed in some cases by insignificant de-

crease), and occlusion of artery and later of the vein also (8 experiments; increase in volume). (2) Epinephrine was intravenously injected, first with unimpeded circulation (11 experiments; rather rapid initial increase, followed by return of volume to normal), then with artery occluded (4 experiments; slow initial increase and following decrease) and with vein occluded (3 experiments; likewise gradual increase and decrease); in all cases with increased blood-pressure. (3) Epinephrine solution (1: 10,000) was intravenously injected over an unspecified period of time at a rate of 2.5 cc. a minute (observations on 4 dogs). The drug exercised its characteristic effect at the moment its concentration in the blood changed; no perceptible effect on the circulation could be seen during continued administration of a given concentration, but increase in dosage raised the volume of the extremity. (4) The left lumbar sympathetic was severed (8 dogs); a momentary increase in volume of the extremity followed; this quickly subsided, and the volume remained unchanged. Intravenous administration of epinephrine produced a marked decrease in volume (but less than with intact sympathetic). In 4 dogs the sympathetic was severed while the animals were under the continuous influence of epinephrine; no increase in volume followed sympathectomy, but either a slight decrease or no change.

16026. **ZWAARDEMAKER, H. L'irradiation par les rayons mous du radium et l'automatisme.** *Arch. Neerland. Sci. Exactes et Nat.* Ser. 3C 12(4): 502-519. 9 fig. 1928.—In those organs whose functions is automatic, K is the carrier of the bioradiactivity. The bioradiactivity causes an unknown mother substance to produce "automatines" (identical with J. Demoor's "active substances" and "l'hormone cardiaque" of L. Haberlandt) having a simple chemical composition. The formation of these "automatines" takes place by means of a radiochemical reaction by which the automatic function is re-established at the end of a long latent period in the organ previously depleted of "automatines."—*Author's résumé (transl.).*

16027. **ZWAARDEMAKER, H., und H. ZECHUISEN. Automatindosis und Frequenz des Herzschlages.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 568-572. 4 fig. 1928.—Frequency of the heart beat is, ceteris paribus, a function of the Ca content of perfusion fluid in simple diffusion experiments; a function of the x-ray dosage in irradiation experiments; and a function of the amount of automatin (a hormone) in circulation experiments. Automatin was produced from automatinogen of the skeletal muscles by activation with x-rays. Normally the P in the tissues plays the rôle of a radio-active substance.

16028. **ADLERSBERG, D., u. A. PERUTZ. Experimentelle Untersuchungen über den Wasserhaushalt der Haut mittels der Quaddelprobe. II. Mitt. Einfluss von lokal auf der Haut applizierten und vom Blut aus wirkenden Stoffen auf die Resorption der intrakutanen Kochsalzquaddel.** *Arch. Exp. Pathol. u. Pharmakol.* 151 (3/4): 129-145. 1930.—Xylol, locally, accelerates and ethyl chloride retards absorption of intracutaneously injected salt solution. Amyl nitrite, theophyllin and "Pituitrin" intravenously accelerate absorption. For the first 2, the known vascular action of the drugs gives an adequate explanation. However, to explain the protracted action of theophyllin and the action of pituitrin, a tissue factor is postulated. The action of a combination of pituitrin and either of the other substances can not be explained as a purely peripheral effect.—*From authors' conclusions.*

16029. **[ADOVA, A. M., and M. I. PANOVA.]** АДОВА, А. М., и М. И. ПАНОВА. О выносливости мышей и морских свинок к экстрактам из семян тыквы. [Tolerance of mice and guinea pigs against extracts of Cucurbita pepo.] [French summary.] Русский Журнал Тропической Медицины, Тропической и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7(5): 326-329. 1929.—An aqueous extract, subcut. in mice, had little toxicity; 0.09 gm. to 1.5 gm. per 100 gm. of body wt. was not lethal. At first the mice lost weight, but they soon regained it. Large doses (1.5-) caused inflammations and sores at the site of injection, which healed in 7-25 days. Ether extract

proved fatal in 15 gm. per 100 gm. wt., but 1-4 gm. caused no particular harm. Original loss of weight was quickly restored, and even surpassed. Guinea pigs showed greater sensitivity both towards water and ether residues. They lost weight, became listless and recovered slowly. Alcohol extract in doses of 0.09-0.27 gm. per 100 gm. wt. showed no harmful effect. In view of negligible toxicity of these extracts, the authors advise testing them as anthelmintics in man and animals.—*B. Van Rosen.*

16030. **ALBI, R. W., and T. E. BOYD. Effect of rectally administered ether-oil mixtures on absorption of histamine from the colon.** *Proc. Soc. Exp. Biol. & Med.* 28(4): 368-369. 1931.—To determine what effect rectal administration of ether (as in anesthesia) may have on the ability of the colon to detoxicate, during absorption, the histamine formed by bacterial activity in the intestine, dogs anesthetized by ether inhalation, with additional ether per rectum, were given histamine dichloride (5 mg. per kg.) per rectum 5-10 min. later. Arterial blood pressure fell immediately. Hence, ether, like alcohol, renders the large intestine permeable to histamine. Normal impermeability was regained in 24 hrs.

16031. **ALLODI, ANGELO, e GIUSEPPE PALOMBA. Valore clinico della ricerca delle lipasi atoxil e chinino-resistenti, e studi delle stesse sotto determinate condizioni. [The atoxyl- and quinine-resisting lipases studied under given conditions.]** *Policlinico [Sez. Med.]* 37 (8): 376-388. 1930.—In 10 out of 11 clinical cases, including 1 normal, serum lipase showed reduction of tributyrin-splitting power; but the atoxyl-resisting lipase after reaction with atoxyl showed much higher lytic power at 50° C than at room temp. To determine if this increased resistance was a power acquired by the lipase at high temp. or an effect of the temp. on the unstable atoxyl, experiments with increasing doses of atoxyl at 50° C. on 6 samples of atoxyl-resisting lipase indicated that the temp. acts on the atoxyl and not on the ferment. In 16 clinical cases stimulation of the pancreas by various means was without effect on the atoxyl-resisting fraction. From study of 37 clinical cases it is concluded that, in the absence of renal lesion, the presence of a quinine-resisting fraction points to the existence of a hepatic affection with obstruction to biliary outflow.

16032. **AMBERG, SAMUEL, and OTTO GROB. The effect of atropine on the bladder of the child.** *Amer. Jour. Dis. Children* 41(3): 507-512. 1931.—In 9 out of 19 enuresis patients aged 6-20 yrs. atropine lowered the pressure of the bladder. The action on the bladder (including effects on amplitude and frequency of contractions) bore no relation to the action on the eye, skin, mucous membrane and pulse.

16033. **ANTONA, LEONARDO, d', e GIULIO CORBINI. Ricerche sul diabete insipido e sulle sindromi ipofisarie. [Diabetes insipidus and the hypophyseal syndromes.]** *Arch. Sci. Med.* 53(12): 705-751. 3 fig. 1929.—In 4 cases of diabetes insipidus, insulin had no effect on the diuresis, epinephrine and ergotamine were doubtfully inhibitory, and the so-called mercurial diuretics constantly decreased the diuresis. Hypophysin had no noticeable effect on the glycemia. In a case of acromegaly with diabetes mellitus insulin alone had scarcely any effect, but in association with synthalin it lowered the glycemia markedly and caused the glycosuria to disappear. In a case of tumor of the hypophysis with diabetes mellitus, the diabetes disappeared when the tumor was reduced and calcified after x-ray treatment. In another case of hypophyseal tumor there was no carbohydrate or hydro-saline disturbance. In view of the variety of clinical syndromes which accompany lesions of the hypophyseal region, the authors suggest that sometimes this may be due to involvement of neighboring cerebral structures.

16034. **AOMURA, TETSUTARO, and TEH-JUN YEN. The minimum effective dose of strychnine in causing the augmented output of epinephrine from the suprarenal gland in the non-anaesthetized, non-fasting dog.** *Tohoku Jour. Exp. Med.* 14(2/3): 93-108. 1929.—The blood of the suprarenal vein was collected extraperitoneally and the epinephrine was determined by means of the rabbit intestine strip. Minimum effective amount was 0.01 mgm. of strychnine nitrate per kgm. body weight. Under ether anesthesia the minimum effective dose was 0.25 mgm. Evidence indicates that the dose needed depends upon the depth of anesthesia.—*R. W. St. Clair.*

16035. **APITZSCH, JOHANNA. Untersuchungen über Calcium und anorganisches Phosphat im Serum bei Calcium und Phosphorbelastung.** *Zeitschr. Ges. Exp. Med.* 76(1/2): 313-324. 1931.—Ca lactate (0.7 gm. per kgm. body wt.) and 1-2 days later Na_2HPO_4 (1.4 gm. per kgm.) were given to 3 subjects, and blood samples taken before and 1 and 3 hrs. after each administration. The maximum Ca occurred at 1 hr.; at 3 hrs. it had sunk about to the initial value; in all instances there was also an elevation of inorganic P. The maximum P occurred at 1 hr.; after 2 and 3 hrs. it was about the initial level; it was accompanied by no particular change in Ca. In 1 patient with a mild, true osteomalacia the Ca administration caused a rise in the Ca and at first a decrease or no change in P. Vigantol treatment gradually increased the Ca and P absorption time and then the P, under the action of Ca, rose. With P administration the P level rose, the Ca rose briefly then fell. In a Ca-poor form of bone defect an elevation of P always followed the Ca overload. With vigantol the curves approached the normal.

16036. **ARRIGO, GAETANO. Sul meccanismo di azione dei diuretici mercuriali. [The mechanism of diuresis by mercurial compounds.]** *Riv. Patol. Sperim.* 5(1): 35-61. 4 fig. 1930.—Hg diuretic compounds do not act on the heart and blood pressure. They cause, at first, a migration of edema fluid into the blood, with increased hydremia. Hydremia causes polyuria. It is possible that it stimulates the kidney through the nervous system.—*M. Comel.*

16037. **ASCOLI, RUGGERO. Ricerche sulla precipitazione dell'Uroselectan da sue soluzioni acide a vario pH. [The precipitation of uroselectan from acid solutions at various pH.]** *Biochim. e Terapia Sperim.* 17(7): 277-286. 1930.—When solutions of urine containing uroselectan are progressively acidified with dilute acetic acid, precipitation of uroselectan occurs at pH 4.6-4.4. Such values approximate those of normal urine. Thus it is advisable to control the reaction of urine when uroselectan is administered; urine must be either moderately acid, neutral or alkaline.—*M. Comel.*

16038. **BAILEY, C. F., and S. M. McELVAIN. Local anesthetics derived from quinoline and isoquinoline.** *Jour. Amer. Chem. Soc.* 52(10): 4013-4017. 1930.—The following hydrochlorides of amino esters were prepared: β-tetrahydroquinolinoethyl benzoate (1); γ-tetrahydroquinolinopropyl benzoate (2); trans-β-decahydroquinolinoethyl benzoate (3); trans-γ-decahydroquinolinopropyl benzoate (4); cis-β-decahydroquinolinoethyl benzoate (5); cis-γ-decahydroquinolinopropyl benzoate (6); γ-tetrahydroisoquinolinopropyl benzoate (7). (1) and (2) were too weakly basic for pharmacological tests. (3) to (6) inclusive were about equal to cocaine in anesthetic power, but less toxic, there was a noticeable difference between the cis- and transisomers. (7) further indicates the potency of phenyl alkyl groups in local anesthetics (cf. C. A. *24*, 2461).—*C. F. Bailey.*

16039. **BALTACÉANO, G., et G. NICHOLESCO. Recherches expérimentales sur les cholagogues.** *Arch. Mal. de l'App. Digest. et Mal. de la Nutrition* 21(2): 182-202. 1931.—Protocols are presented of 11 exps. on dogs under chloralose anesthesia studying the volume of bile flow and its concentration following the intraven. and intraduodenal administration of many substances. Pyramidon, Na_2SO_4, urotropin, and boldine have no effect; pituitary extract, epinephrine, angioxyl, coramine and sulfurion decrease the flow; while opobyl, atophan, atophanyl, sodium salicylate, sodium benzoate and certain mineral waters stimulate flow but decrease the solids. Insulin has little effect when given alone but its slight stimulating action is increased by simultaneous administration of glucose. Likewise aspirin is synergized

by pyramidon, sodium benzoate and lithium iodate.—*F. R. Vanzant.*

16040. **BANCROFT, WILDER D., and GEORGE H. RICHTER. Claude Bernard's theory of narcosis.** *Proc. Nation. Acad. Sci.* 16(9): 573-577. 1 pl. 1930.—The Overton-Meyer theory is accepted as applying to permeability, but not in any proper sense to narcosis. Bernard's theory of reversible coagulation of the colloids of sensory nerves was verified by photomicrographic studies of live yeast cells treated with 2% amyl alcohol; coagulation and flocculation occurred in 25 min.; the time varied with temp. and concentration of narcotic and culture. Centrifuged treated cultures were revived in fresh media (Laurent's). Non protein-coagulating gases (N_2O) give rise to acid metabolic products which cause flocculation. Bernard's theory offers a clue to a scientific method of countering habit-forming drugs.—*S. E. Owen.*

16041. **BARBER, M. A., W. H. W. KOMP., and B. M. NEWMAN. The effect of small doses of plasmochin on the viability of gametocytes of malaria as measured by mosquito infection experiments.** *U. S. Publ. Health Repts.* 44(24): 1409-1420. 1929.—Plasmochin in small doses, in one case in a single dose of 0.5 cgm., had a definite effect on the viability of crescents as measured by mosquito infection tests. Degenerative changes in crescents after the use of plasmochin did not appear definite enough to measure the early effects of small doses of plasmochin. It is probable that the general use in a population of such small doses of plasmochin would be safe and effective in reducing the transmission of malaria.—*Authors' summary.*

16042. **BARCHI, LUIGI. La chemioterapia della rabbia. [The chemotherapy of rabies.]** *Policlinico [Sez. Med.]* 37(11): 533-540. 1930.—In experiments on 27 rabbits (including 5 controls), Pb, Sb, Sn, and As in elemental form or colloidal solution, neutral lead acetate, and Na arsenate failed to exert any influence on rabies, either during incubation or during the clinically evident stage.

16043. **BAYER, G. Organotherapie. [In: HERMANN THOMS. Handbuch der praktischen und wissenschaftlichen Pharmazie. Bd. 4. D. Grundlagen und Richtlinien der Therapie. Lief. 14.]** p. 924-946. 1 fig. Urban & Schwarzenberg: Berlin u. Wien, 1926.

16044. **BERCEANU, D., et S. BALCU. L'accélération de la cicatrisation des plaies par le propidon.** *Bull. Assoc. Française Étude Cancer* 18(3): 285-287. 1929.—Subcutaneous injections of propidon have been found to increase the absolute number of both red and white blood cells, changing the leukocytic formula by increasing the absolute number of polynuclear neutrophiles, eosinophiles and basophiles, and especially young leukocytes and large mononuclears. Having observed that the reconstitution of conjunctive epidermal tissue which takes place during cicatrization is accompanied by multiplication of the blood cellular elements mentioned above, the authors observed the cicatrization of wounds in 10 guinea-pigs, 5 of which received preliminary injections of propidon while 5 did not, all being then subjected to the same type of wound. The wounds in the animals which had received propidon healed completely in 16-18 days; in the controls, in 25-30 days.

16045. **BERGAMI, GINO. Ricerche sul meccanismo di eliminazione dell'acido urico iniettato endovena. [Studies on the mechanism of elimination of uric acid introduced by intravenous injection.]** *Biochim. e Terapia Sperim.* 17(7): 310-322. 1930.—Uric acid, intraven., in rabbits and dogs, disappears quickly from the blood. The non-protein N increases immediately after the injection, and persists longer than the increase in uric acid concentration. The uric acid is fixed almost exclusively by the kidneys, in which edema develops. The uric acid content of the kidney falls gradually, and its value is normal after some hrs. In the days following uric acid injection the elimination of uric acid with the urine is but little increased, and so is the elimination of urea and ammonia. This increase is less than the amount of uric acid administered, a positive balance resulting.—*M. Comel.*

16046. **BERGMAN, ROLF. Prophylaktische und therapeutische Versuche mit Wasserextrakt aus ultraviolettbestrahltem bzw. ozonbehandeltem Fischlebertran bei experimenteller Meerschweinchentuberkulose.** *Zeitschr. Tuberk.* 57(1/2): 50-57. 1930.—In experiments on 18 guinea pigs with 5 controls the authors tried to find out whether previous or subsequent treatment of guinea pigs, infected with tuberculosis, with watery extract of irradiated and ozonized cod-liver oil, would protect these animals from tuberculosis or alter its course. No such results were obtained; but the indurative changes in the animals prophylactically treated with ozone water were more pronounced than in the other animals.—*Author's summary (transl. by N. Savitsky).*

16047. **BISCHOFF, FRITZ, and M. LOUISA LONG. The depletion of muscle sugar by adrenalin.** *Jour. Biol. Chem.* 87(1): 47-53. 1930.—The blood sugar and muscle sugar values do not run parallel after the subcut. administration of 0.25 mgm. of adrenalin per kgm. to the rabbit. From the 8th to the 24th hr. the muscle sugar is at a very low level. At the 3rd hr. the muscle sugar has already fallen to the fasting value, while the blood sugar is at the peak of the curve. The in vitro experiments of Sahyun and Alsberg, which indicated that deglycogenated whole skeletal muscle has the power of utilizing glucose in vitro, are invalidated by the above observations.—*Authors' conclusion.*

16048. **BLICKE, F. F., and E. S. BLAKE. Local anesthetics in the pyrrole series. II.** *Jour. Amer. Chem. Soc.* 53(3): 1015-1025. 1931.—Eight analogs of novocaine and several compounds analogous to stovaine and β-eucaine have been prepared and tested for local anesthetic action by application to the tip of the tongue. So far as the compounds discussed in this paper are concerned, the local anesthetic action of a compound was retained on the substitution of 2-pyrroyl for the benzoyl and the 4-aminobenzoyl group and on the replacement of dimethyl- and diethylamino by the 1-pyrryl and 1-pyrrolidyl nuclei.—*Authors' summary.*

16049. **BLUHM, AGNES. Zum Problem "Alkohol und Nachkommenschaft." Eine experimentelle Studie.** 87p. J. F. Lehmann: München, 1930.—The experiments were carried out on some 30,000 white mice, in order to rule out errors due to small numbers. For the determination of experimentally produced changes, both control and test animals were taken from a closely inbred series, which in turn was taken from a closely inbred race. Where it was not possible to get 2 pairs from the same litter the 2 ♂♂ (test and control) were from 1 litter, and the 2 ♀♀ from another litter of the same pair of parents were used. In a few cases, the ♂♂ were taken from one, and the ♀♀ from another of 2 inbred series from a common stem. This also permitted genetic comparisons. To limit the action of alcohol as much as possible to the germ plasm, only ♂♂ were treated with the drug in the initial generation. The alcohol was injected subcutaneously, and for the first 1½ yrs. of the experiment, the control ♂♂ were injected with salt solution, but without any evident influence on the progeny. Tolerance to alcohol developed rapidly with doses of 0.2 cc. of 15% alcohol solution. Injections were begun at about the 4th mo. of life, and were adjusted so as not to decrease the libido sexualis, the dose averaging about 0.0015 cc. absolute alcohol per gm. body weight. The initial generation consisted of 114 test and 114 control pairs. From these, matings were largely of sister and brother of the same litter, although sisters and brothers of different litters of the same parents were also mated, as well as half-brother and sister, cousins and uncle and niece. Finally, there were a large number of crossings and back-crossings between the progeny of the alcohol group and the test group. Observations made were concerned with longevity, growth in weight and organ development, fecundity, fertility, abnormalities and degenerations. Special care was taken to control effects of temp. changes and season. An increased prenatal mortality in the alcohol group was evidenced by smaller litters, increased mortality in the suckling period was shown in

the 1st and 2nd generation from alcoholized ♂♂, with decreasing mortality in the succeeding 5 generations. The increase in the mortality among the young from alcoholized ♀♀ was not so great. In both cases increased mortality was associated with an "intestinal catarrh." Young from alcoholized parents showed a lessened mortality in the age group of 3 to 8 weeks, but in later life up to the 10th mo. showed a marked increase again. The body weights averaged less and showed greater variability, and the development of eyes and ears was retarded in alcohol young. Both fecundity and fertility were decreased; there was also more evidence of degenerative changes. It was also evident that throughout the series of observations, young from alcoholized ♂♂ were at a greater disadvantage than those from alcoholized ♀♀. The author concludes from her data that alcohol administration resulted in a definite mutation, resulting from alteration in the X and Y chromosomes. —*C. H. Thienes.*

16050. **BOSCO, I. Influenza del fumo di tabacco sul potere amilolitico della saliva. [Action of tobacco smoke on the amylolytic power of saliva.]** *Riv. Patol. Sperim.* 5(2/3): 187-199. 2 fig. 1930.—Acute poisoning from tobacco smoke produces a great decrease in the amylolytic activity of saliva. Following chronic poisoning a complete loss of amylolytic activity may result. When administration of smoke is discontinued, activity is gradually restored, the time depending on the severity of intoxication. The action of smoke is attributed to a modified metabolism of the salivary glands which show histological alterations.—*M. Comel.*

16051. **BRAHMACHARI, U. N. The relation between the chemical constitution of antimonials and their therapeutic properties.** *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 468-480. 1927[1928].—The relationship of the chemical constitution of the following antimonials to their therapeutic properties are discussed: Metallic Sb, Sb trioxide, the antimonyl tartrates and malates, acetyl-p-amino-phenyl-stibinate of Na, p-amino-phenyl-stibinate of Na, urea-para-stibanilate, ammonium-carbamino-stibanilate (urea-stibamine), N-phenyl-glycine-amide-p-stibinate of Na.

16052. **BRANDHENDLER, W. Über die Umkehr der Wirkung des N. vagus und N. splanchnicus auf die Darmbewegungen unter dem Einflusse von Kalium und Calcium.** *Arch. Exp. Path. u. Pharmakol.* 138(1/4): 219-227. 17 fig. 1928.—A study was made of the influence of K and Ca ions on the action of the vagus and splanchnic nerves to test the assumption that K ion is a specific excitant of the parasympathetic and Ca ion of the sympathetic nerves. Dogs were placed under ether-chloroform anesthesia and contraction of the jejunum recorded by the balloon method. (1) The peripheral ends of one vagus nerve and the left splanchnic nerve were stimulated to get the normal effect. The vagus nerve was found to be motor to the gut (occasionally inhibitory), the splanchnic, inhibitory. (2) Injections of 5% KCl (2-5 cc.) and of $CaCl_2$ (10 cc.) into the femoral vein were made in different series. Both ions caused inhibition of the intestinal movements followed by a return to normal or even greater contraction. (3) Injection of Ca as well as of K ion followed by stimulation of the vagus or the splanchnic nerve usually produced a reversal of the action of the nerves, e.g., inhibition on stimulating the vagus nerve and contraction on stimulating the splanchnic n. The optimum amount of salt necessary to cause the reversal could not be determined since it is variable in different animals. It is suggested that the "milieu of the nerve" and the condition of the organ which it innervates are important factors which complicate the relationship between nerve action and specific ions.—*A. C. Ivy.*

16053. **BRANDHENDLER, W. Einfluss von Pilokarpin und Physostigmin auf das isolierte Katzenherz nach Degeneration beider Nn. vagi.** *Arch. Exp. Path. u. Pharmakol.* 140(3/4): 168-173. 1929.—Pilocarpin and physostigmin act on the isolated cat heart in which the vagus nerves have degenerated in the same way that they do on the normal heart. The vagus nerves degenerated 4 days after resection. The author believes that the point of action of pilocarpin and physostigmin on the heart is peripheral to the vagus nerve ending.

16054. **BRETT, P. C., W. A. BROOM, and W. A. HOWITT. The action of liver preparations in diabetes.** *Lancet* 220(5601): 19-21. 1931.—The authors have carried out Blotner and Murphy's directions for the preparation of this special extract of liver on several occasions, and have consistently found the extract ineffective in lowering the blood-sugar of normal rabbits when administered in suspension by stomach-tube in doses equivalent to 1/10 of a lb. of liver, a quantity which, according to Blotner and Murphy, is equivalent to about 1 unit of insulin. In the authors' experience an injection of 1 unit of insulin produces a considerable fall in blood-sugar in the type of rabbits usually used for insulin assay. Extracts were prepared from both fresh and frozen liver by the Blotner and Murphy process and extraction periods of both 12 and 48 hrs. were tried, but in no case was any hypoglycemic effect observed. Liver extract (Boots), prepared by the Medical Research Council's process (see The Lancet, 1928, ii., 514), had no hypoglycemic action. In fact, in practically all cases a slight but definite hyperglycemia resulted.

16055. **BRUGSCH, HEINRICH, und HANS HORSTERS. Insulingehalt und Insulinverteilung im Blut.** *Arch. Exp. Pathol. u. Pharmakol.* 148(5/6): 295-308. 1930.—Venous blood of non-insulinized men and animals contained less than 0.0125 units of active insulin in 0.2 cc., or a maximum of 5-6 units per 100 cc. After intravenous doses of 25 units per kgm. in rabbits and dogs, blood insulin can be quantitatively determined. It was present even 90 min. after injection. Injection of 40 units per kgm. into the portal vein in narcotized animals caused an increase in blood sugar. Insulin could be demonstrated in the iliac vein 1½ hrs. after injection of insulin into the portal vein. Active insulin was always found in the plasma; never in the corpuscles. Fasting blood from both healthy and diabetic men did not produce a hypoglycemic action in mice. Therefore it contained less than 6 units of insulin per cc. Thirty to 120 min. after subcutaneous injection of insulin, 30-50 units of insulin could be demonstrated in the peripheral venous blood. The duration of insulinemia depended on the amount of insulin injected subcutaneously.

16056. **BRÜHL, HEINZ. Untersuchungen zur Membrane und Eiweisswirkung des Coffeins.** *Biochem. Zeitschr.* 212(4/6): 291-317. 1 fig. 1929.—Filtration experiments with collodion membranes saturated with protein showed a reversible increase of permeability (1) in the presence of caffeine, and (2) by shifting the reaction towards the iso-electric point of the protein. The latter procedure causes changes of the swelling condition, the caffeine acts by changes of the degree of dispersity of the proteins coating the walls of the pores. The changes of proteins caused by caffeine are a physico-chemical phenomenon. Caffeine increases the dispersity of hydrophilic and hydrophobic colloids and the solubility of amino acids, presumably on account of the formation of complex compounds of greater solubility. Such compounds may be detected by compensation dialysis for proteins, and by freezing point determination for amino acids. The diuretic action of caffeine is discussed in relation to these filtration experiments.—*W. F. von Oettingen.*

16057. **BUCHBINDER, WILLIAM C. The effects of strophanthin and of quinidine on the rate of fibrillation of the tongue following hypoglossotomy.** *Amer. Jour. Physiol.* 91(2): 654-660. 1930.—The rate of oscillation of the fibrillating tongue following hypoglossotomy in 8 adult dogs was approximately that of the fibrillating auricle. Quinidine sulphate produced a marked slowing of the rate of oscillation of the fibrillating tongue; strophanthin greatly augmented it.

16058. **BURCH, JOHN C., and T. R. HARRISON. The effect of spinal anesthesia on arterial tone.** *Arch. Surg.* 22(6): 1040-1044. 1931.—A "reverse perfusion"

method (described) was used. In 2 normal dogs hemorrhage was followed by an initial vasoconstriction, and subsequent vasodilatation and death. In 2 out of 3 spinally anesthetized dogs the perfusion rate was practically unchanged; in the 3rd it was increased. In 8 out of 9 dogs spinal anesthesia was followed by a marked vasodilatation, in 4 cases observed in the unanesthetized area, but running especially high (up to 200%) in the 4 anesthetized areas observed. The bearing of these observations on current conceptions of shock is discussed, and the suggestion made that the terms neurogenic and hematogenic be substituted for primary and secondary shock, resp.

16059. **BURCH, JOHN C., and T. R. HARRISON. The effect of ephedrin on the circulation of dogs during spinal anaesthesia.** *Surg., Gynecol. and Ostetr.* 52(5): 953-954. 1931.—Given intravenously to 7 dogs under spinal anesthesia, ephedrine raised blood pressure and cardiac output; given intraspinally to 7 other dogs, it caused an even greater rise in blood pressure. The previous administration of ephedrine intraspinally abolished the usual vasomotor effect of spinocaine.

16060. **BÜRGER, M., und H. KRAMER. Über den muskulären Angriffspunkt des Insulins.** *Zeitschr. Ges. Exp. Med.* 61(3/4): 449-464. 1928.—That insulin had its chief point of action in the musculature, especially that of the extremities, was indicated by injecting insulin (0.4 units per kgm.) intravenously, while the iliac and subclavian arteries were compressed, or ligated, and again after they were freed. The great fall of blood sugar occurred when the limbs were in the circulation.—*R. H. M'Gonigle.*

16061. **BURN, J. H. The present position of ovarian hormones.** *Quart. Jour. Pharm. and Pharmacol.* 2(1): 63-75. 5 fig. 1929.—A review.

16062. **BURNS, CLARICE MARGARET. Factors influencing bone formation in the albino rat. I. The effect of guanidine intoxication produced by the successive injection of sub-lethal doses of guanidine salts.** *Biochem. Jour.* 23(5): 840-852. 1929.—Injections of guanidine do not cause the deposition of Ca in rachitic rats. The injections do not cause decalcification of formed bones.—*E. B. Carmichael.*

16063. **CALDWELL, FRED. C., and ELFREDA L. CALDWELL. A study of the anthelmintic efficiency of higuerolatex in the treatment of trichuriasis with comment as to its effectiveness against ascaris infestation.** *Amer. Jour. Trop. Med.* 9(6): 471-482. 1929.—A preparation of the fresh sap of *Ficus laurifolia,* "higuerolatex," kept cool and in dark bottles for over a year, was used. In the treatment of 9 patients in 1927 each with about 30 cc. of this drug, and 117 patients in 1928 with 60 cc. ea., a reduction in egg output of 89.5% and 85.4% respectively, was obtained. 22.2% of the patients of the first group were cured, and 53.8% in the larger group. A variation in the percentages of cures in the different infection intensity groups (A, 74.5; B, 46.0; C, 32.7; D, 0.0) suggests that 2 treatments should remove practically all worms. The treatment of an equal number of patients with 1.5 cc. ea. oil of chenopodium resulted in only 17% reduction in egg output, and 1.7% cure. In the group treated with higuerolatex the ascaris egg output of 37 infested patients was reduced 89.7% and 70.3% were presumably cured. A bibliography is included.—*R. Shosteck.*

16064. **CALVANO, A., e V. MONTUORO. Attività del curaro sulla capacità deidrogenativa dei tessuti. [Action of curare on dehydrogenation capacity of tissues.]** *Riv. Patol. Sperim.* 5(6): 460-463. 1930.—Curare acts on the tissues by activating their oxidative cellular processes, this activation occurring in all the tested tissues; muscle, kidney, liver, brain (of guinea pigs).—*M. Comel.*

16065. **CANNICCI, GABRIELLA. Sull'uso dell'Erba Mora (Daphne gnidium L.) nella pesca di frodo.** *Boll. Pesca, Piscicolt. e Idrobiol.* [*Roma*] 4(1): 1-11. 1928.—The so-called black weed used for illegal fishing is *Daphne gnidium,* and not the deadly nightshade *Solanum nigrum* which latter does not affect fish. *Daphne* is used as an irritant and vesicant. Experiments on carp indicate that its toxicity is probably due to a resinous vesicant principle, and that its action is indirectly irritant to the gills so as to impede respiration. Endoperitoneal injections of *Daphne* extract do not produce a quicker reaction; nor are any recognizable lesions caused.—*G. Cannicci (transl. by R. A. Muttkowski).*

16066. **CARONIA, G. The therapy of internal leishmaniasis.** *Amer. Jour. Trop. Med.* 10(4): 261-281. 1930.—A review of the development of the highly successful Sb treatment.

16067. **CASSER, HERMANN. Herzarbeit ohne Sauerstoff. V. Hemmung der Blausäurewirkung durch Dioxyazeton und Glyzerinaldehyd.** *Arch. Exp. Path. u. Pharmakol.* 149(3/4): 240-246. 1930.—Injury to the heart by cyanic acid (CNHO) is prevented by dioxyacetone and glycerine aldehyde. Both substances are inactive in the absence of O_2. The inhibition of respiration in birds' erythrocytes by KCN was eliminated by dioxyacetone and glycerine aldehyde. Both substances produce chemical detoxication through formation of cyanhydrin.—*Author's abstract (transl.).*

16068. **CATEL, W. Über die Wirkung der Kohlehydrate auf Darmperistaltik und Kammertätigkeit des Herzens. (Tierversuche.)** *Jahrb. Kinderheilk.* 130(5/6): 305-325. 1931.—In vitro experiments (40) on guinea pig intestines with 1-6% solutions of lactose, levulose, glucose, Koch's sugar, saccharose, and Soxhlet's nutritive sugar, decreased peristalsis. In concentrations of 0.2-1% a stimulating action was observed. In Straub summer frog hearts 5-6% solutions of the sugars in Ringer's solution almost without exception had a positively inotropic action; winter frog hearts were negatively inotropic or negatively chronotropic; this varying action is attributed to altered metabolism during hibernation. It is concluded that the carbohydrate did not attack the musculature directly but the vegetative nervous system. The positive, inotropic action of milk sugar can be suppressed by ergotamin.

16069. **CHAHOVITCH, X. Antagonisme de l'action de l'atropine et de l'insuline.** *Compt. Rend. Soc. Biol.* 100(14): 1215-1217. 1929.—Rabbits injected with 1.5 mgm. of atropine SO_4 and later treated with insulin did not develop insulin convulsions as rapidly as the controls. An increase in blood sugar followed atropine treatment. This is believed to be the cause for the antagonism. Smaller doses did not modify the normal blood sugar.

16070. **CHAHOVITCH, X. Sucre protéidique et décaméthylènediguanidine.** *Compt. Rend. Soc. Biol.* 100(14): 1218-1219. 1929.—The free and protein sugars of 10 rabbits were determined before and after treatment with synthaline. The increase in protein sugar does not explain the action of synthaline in lowering free blood sugar in the normal animal.

Soc. Argent. Biol. 5(5/6): 376-385; **Histopatología del hueso, riñón, hígado, bazo, corazón suprarrenal, testículo y tiroides de ratas sometidas a una dieta fluorada con y sin tratamiento actínico y a una dieta fluorada y yodada.** [Pathology of tissues and viscera in experimental fluorosis.] *Rev. Soc. Argent. Biol.* 5(5/6): 386-396. 2 fig. 1929.—Young rats receiving 50 mgm. per kgm. of F daily, increased more rapidly in weight than the controls during 3 to 4 mos., then less rapidly so that at the 6th mo. their wt. was 20% less than that of controls. Only towards the end was cachexia observed. Females are more sensitive than ♂♂; the sexual cycle is suppressed, as determined by vaginal smears; only 1 became pregnant and delivered a normal litter. Animals treated with I had similar but more severe symptoms. Controls that received only I grew better and had finer aspect than normal controls. The incisors of fluorized rats had a dirty white color, the inferior incisors grew to a considerable length, curving backwards gradually; lesions were somewhat similar to those seen after parathyroidectomy. Ca content of bones and teeth was the same as in controls. There was less P and Mg in the incisors of fluorized rats and more P but less Mg in those that received light treatment. Fluorized rats, treated and untreated by light had more P and Mg in bone, than was found in controls. In ground sections the dentin was seen longitudinally laminated. In decalcified sections the enamel showed marked irregularities, the dentin was not homogeneous but disposed in irregular layers with calcospherites, the dentinogenous layer was thickened and sinuous, the pulp considerably widened. The incisors were more affected than the molars. Rats receiving violet light treatment had less severe lesions. No important alterations were found in other tissues. The thyroid was not increased in wt. and did not show microscopic signs of hypertrophy.—*J. T. Lewis.*

16072. [CHECHULIN, S. I.] ЧЕЧУЛИН, С. И. **Стандартизация препаратов спорыньи и некоторые физиологические наблюдения над свойствами Secale и гистамина.** [**The standardization of preparations of ergot, with some physiological observations on the properties of ergot and histamine.**] [German summary.] Труды Научного Химико-Фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 110-131. 2 fig. 1926.—The method of assay described by Storm von Leeuwen contains numerous sources of error. Although uteri of virgin guinea pigs of definite weight were used, consistent results could not be obtained. Repetition of the experiments of ergot action on the uterus, the uterus being flushed between tests, yielded a degree of activity which is altered by the sensitization of the organ by repeated doses; the time of flushing and duration of intervals play a great rôle. These questions were clarified in experiments showing that comparable results can be obtained if at the beginning of the assay 1-2 doses of ergot equal in their activity, are applied; then the histamine response is determined; and then the same dose of ergot is given, the effect being equilibrated to a definite dose of histamine. Ten min. must elapse between the applications. The apparatus for application and washing is automatic. The "Value" is reckoned from the formula $V = (0.02D\beta\ cm^3\ 100)/(Ds\ cm^3)$ where 0.02 is a constant for the use of 1 mgm. of histamine in 50 cc. water, and $D\beta$ and Ds are the doses of β-imidazolethylamine and of ergot extract which are equivalent. The ergot extract is aqueous, 1 gm. per 1 cc. water.—*Author's summary (transl.).*

16073. **CHIKANO, M. Über den Einfluss von Aminosäuren und ihren Abkömmlingen auf die Adrenalinhyperglykämie.** *Biochem. Zeitschr.* 205(1/3): 154-165. 1929.—Tyrosine or tryptophane (0.5-1 gm. subc.) in rabbits accentuate the effect of epinephrine on the blood sugar. Tyrosine alone has no effect. Tryptophane causes a slight hyperglycemia. The blood sugar is raised by 0.2 to 0.3 gm. of 3, 4-dioxyphenylalanine. Leucine (1 gm.) and histidine (0.5 gm.) inhibit epinephrine hyperglycemia. Phenylalanine, glutamic acid, and glycocoll have no effect on epinephrine hyperglycemia. *p*-Oxyphenyl pyruvic acid accentuates, while *p*-oxyphenyl lactic acid has no effect on epinephrine hyperglycemia. Pyrocatechol (0.2 gm.) raises the blood sugar.—*G. T. Cori.*

16076. **CHOPRA, R. N., and J. P. BOSE. The action of opium in diabetes.** *Indian Jour. Med. Res.* 18 (1): 15-26. 1930.—Small doses of opium—1 to 6 grains daily—produce a slight reduction in total urine excreted in mild cases. In severe cases it does not reduce polyuria, thirst or frequency of micturition. In the early and mild cases opium has a well marked effect in reducing the total daily output of sugar in the urine; in some cases the sugar entirely disappears. In severe cases, however, it has no effect on sugar output. Opium has little effect in reducing the amount of blood-sugar of diabetics; in fact in severe forms it actually increases it. In some patients it distinctly raises the renal threshold for excretion of sugar.

16077. **CIAMBELLOTTI, E. Studi sulla terapia calcica. III. L'azione sul cuore del calcio iniettato per vena.** [**Effect of intravenous injections of Ca on the heart.**] *Boll. Soc. Ital. Biol. Sperim.* 4(6): 769-772. 1929. —Intraven. injections of Ca lead to a more or less acute feeling of heat, followed by grave symptoms of collapse. Sphygmographic studies show that a group of systolic pulsations gradually amplifying, with short diastole about as normal, alternates with a group in which the systole diminishes until it becomes barely perceptible, while the diastole increases. The possible mechanism is discussed.—*E. Ciambellotti (transl. by P. Popenoe).*

16078. **CIAMBELLOTTI, E. Studi sulla terapia calcica. V. La associazione calcio-magnesio.** [**Ca Therapy: the association of Ca and Mg.**] *Boll. Soc. Ital. Biol. Sperim.* 4(6): 775-777. 1929.—Associating either an organic or an inorganic salt of Mg with Ca, the author succeeded in producing all the accustomed effects of Ca in therapeutics, without the circulatory disturbances usually found. This is explained as due to the difference in speed of action of the 2 elements. Small amounts of Mg were found to stimulate the spinal nervous system.—*E. Ciambellotti (transl. by P. Popenoe).*

16079. **CLIMENKO, DAVID ROBERT. Studies on the Arneth count. XVII. The effect of alternations of the serum-calcium level on the count.** *Quart. Jour. Exp. Physiol.* 20(4): 369-377. 1930.—A number of patients who were being treated with irradiated milk were examined. They showed no change in the Arneth count and the serum Ca level. Oral administration of colloidal Ca preparation in rabbits did not raise the serum Ca level and had no effect on the count. Intramuscular injections of a colloidal Ca preparation and Ca Cl_2 (intraven.) raised the serum Ca level and produced a regenerative deflection of the count. Intraven. injections of hypotonic sols. had no demonstrable effect on the serum Ca level, but caused a regenerative deflection of the count. Intraven. injections

of physiological saline sols. had no effect on the serum Ca level and none on the count.—*Author's summary.*

16080. COLLIER, W. A., und MAGDALENE KRAUSE. Zur Chemotherapie der Halteridieninfektion des Reisfinken. *Zeitschr. Hyg. und Infektionskr.* 110(3): 522-525. 1929.—Since the plasmodium infection of the canary is interrupted by parasite-free intervals, it is difficult, when testing the effect of any drug on the parasite in this bird, to judge whether the disappearance of the plasmodia is due to the treatment or to the natural protective forces of the canary. The employment of a bird subject to a chronic or at any rate non-fluctuating infection therefore seems preferable. The authors tested plasmochin on the natural *Halteridium* infection of 9 freshly imported African rice-finches (3 controls) and believe that the effects indicate the greater suitability of this bird for testing antimalarial drugs.

16081. COOPER, ZOLA K., and MARTIN F. ENGMAN. A study of the stimulating effect of small doses of thallium acetate on the rate of the growth of hair in the albino rat. *Arch. Dermatol. and Syphilol.* 23(6): 1031-1040. 1931.—Single doses of 0.004 and 0.006 gm. of thallium acetate per kgm. of body weight, dissolved in distilled water and injected intraperitoneally into white rats, produced a stimulation of 18% in the rate of the growth of hair. Doses of 0.002 gm. per kgm. of body weight were too small to produce any effect on the rate of the growth of hair.—*Authors' summary.*

16082. CSÉPAI, K., und J. FERNBACH. Über den Einfluss des Parathormones auf die Adrenalinempfindlichkeit des menschlichen Organismus. *Zeitschr. Ges. Exp. Med.* 60(5/6): 618-621. 1 fig. 1928.—The authors were unable to confirm the findings of Kylin who claimed that the vagotonic influence showed an increased sensitivity to epinephrine following the administration of parathyroid hormone. The investigators used the Collip parathyroid hormone in the case of bronchial asthma and were unable to note the slightest change in epinephrine sensitivity.—*D. Perla.*

16083. DAVID, NORMAN A., and CHAUNCEY D. LEAKE. The toxicity and balantidicidal action of "dihydranol" in guinea pigs. *Proc. Soc. Exp. Biol. and Med.* 28(2): 196-199. 1930.—2-4 dihydroxy-phenyl-*n*-heptane ("di-hydranol") causes death in guinea pigs in about 4 days with symptoms of loss of weight, diarrhea, and lethargy at an average dose of 400 mgm. per kgm. on single oral administration. In natural *Balantidium coli* infestations in guinea pigs, it seems to be curative at a total of 200-225 mgm. per kgm. on continued administration at 1-2 day intervals of 75 to 100 mgm. per kgm. Toxicity may be encountered at a total dosage only slightly higher than this indicated curative range on continued administration of the sublethal doses proposed.—*Authors' summary.*

16084. DAWSON, W. T., and FRANCIS A. GARBADE. Idiosyncrasy to quinine, cinchonidine and ethylhydrocupreine and other levorotatory alkaloids of the cinchona series: preliminary report. *Jour. Amer. Med. Assoc.* 94: 704-705. 1930.—A subject with anaphylactoid reaction to administration of quinine and cinchonidine but not to quinidine nor cinchonine showed a positive skin test (wheal formation) to quinine, cinchonidine, hydroquinine, hydrocinchonidine, cupreine, hydrocupreine, ethylhydrocupreine, ethylquitenine, but not to the dextrorotatory isomers, quinidine, cinchonine, hydroquinidine, hydrocinchonine, hydrocupreidine, ethylhydrocupreidine, ethylquitenidine, nor to nitro- nor chloro-hydroquinine, nor nitro- nor amino-ethylhydrocupreine. This supports the observation of Giemsa that a person with malaria who does not tolerate quinine may be able to take quinidine, which is also effective.—*W. T. Dawson.*

16085. DAWSON, W. T., and FRANCIS A. GARBADE. Idiosyncrasy to quinine, cinchonidine and ethylhydrocupreine and other levorotatory alkaloids of the cinchona series: further chemical delimitation of the idiosyncrasy; alteration in sensitiveness. *Jour. Pharmacol. and Exp. Therapeut.* 39: 417-424. 1930.—Further investigation shows that a subject who had given positive results on skin testing with quinine and some other levorotatory alkaloids of the cinchona series but not with corresponding dextrorotatory isomers, as quinidine, was skin-sensitive to the levorotatory amyl- and isoamyl-quitenine, propyl-, isopropyl-, isobutyl-, isoamyl-hydrocupreine, apoquinine; to the dextrorotatory quinicine and cinchonicine in strong solutions, but these last two appeared to be mere irritants as they gave similar results in normals; not sensitive to the levorotatory hexyl- and dodecyl-hydrocupreine, quitenine and cinchotenidine, aminohydroquinine, nor the dextrorotatory quinamine, cinchotenine, quitenidine. Quinoline gave a positive result, plasmochin a negative. Subject was initially not sensitive to isoamylhydrocupreine. An attempt has thus been made by a study of skin reactions to delimit some of the "chemical boundaries" of an anaphylactoid reaction to quinine.—*W. T. Dawson.*

16086. DESSY, GIORGIO. La chemioterapia della streptotricosi. [Chemotherapy of streptococcus infection.] [German summary.] *Boll. Istituto Sieroterapico Milanese* 7(1): 25-44. 1928.—Experiments on the chemotherapy of streptococcus infections, carried on for 1 yr., with 59 dyes and 20 metal salts, yield following conclusions: Dyes, particularly those belonging to the group of triphenylmethane, triazin, ossiazin, and acridin, possess in vitro a complete inhibitive and bactericidal power. Other dyes have not only no bactericidal power, but on the contrary favor the growth of cultures up to dilutions of 1:500. The most powerful growth inhibiting and bactericidal metals are: Cd, Au, U, Al, Cu, Zn, Ni, Ce, and Th. There is a general agreement with the results of the germicidal action of the dyes tested by the author and those obtained by Karwacki and Biernacki in their experiments on the tubercle bacillus. This agreement exists also in regard to the action of the metal salts, with the exception of Ba which, according to Walbum, showed a distinct chemotherapeutic action upon tubercle bacillus, while this author found it to be ineffective upon streptococcus infection. Experiments in vivo (for orientation) gave the following results: A number of substances (dyes, metals) which possess a germicidal action in vitro, also possess this chemotherapeutic action in vivo. Most of these substances do not prevent the formation of a streptococcus granuloma but limit the process and eventually cure it. Several substances apparently prevent the formation of the granuloma (at least when the organisms are injected simultaneously); among these are methylviolet, picktannin, Ni and Al. Uranium acetate possesses strong toxic action and caused death of the animals in the amounts used in these experiments.—*Author's summary (transl. by F. R. Greenbaum).*

16087. DICKENS, F., and F. ŠIMER. Observations on tissue glycolysis: the effect of fluoride and some other substances. *Biochem. Jour.* 23(5): 936-958. 3 fig. 1929.—Fluoride and oxalate inhibit anaerobic glycolysis in tissues and the former has the stronger action. Fluoride belongs to the category of specific inactivators and does not destroy the "glycolytic enzyme." Aerobic glycolysis was inhibited by fluoride in the case of Jensen rat sarcoma, but not in the rat testis.—*E. B. Carmichael.*

16088. DIMITRIJEVIC, IL. N. Der Blutzuckerspiegel im Pernoktonschlafe. *Arch. Exp. Pathol. u. Pharmakol.* 151(1/2): 91-99. 1930.—The narcotic range of Pernocton in rabbits is not so wide as previously reported. Narcotic doses occasionally cause a slight increase in blood sugar. Epinephrine-hyperglycemia is not changed by the narcosis, but insulin hypoglycemia seems to be somewhat prolonged. Although ergotamine in small doses produces a mild hypoglycemia in control animals, this effect does not appear in Pernocton narcosis. The hyperglycemia from Pernocton is probably due to a depression of the inhibitory apparatus in the brain stem.—*Author's summary.*

16089. DINGEMANSE, ELISABETH, und J. P. WIBAUT. Zur Pharmakologie von einigen Pyridylpyrrolen und einigen Abkömmlingen des a-Aminopyridins. *Arch. Exp. Path. u. Pharmakol.* 132(5/6): 365-381. 1928.

—On frog, rabbit and cat the following results were obtained: α aminopyridine produces, after a period of paralysis, signs of spasms; the acetyl derivative acts more as a cataleptic. The pyridylpyrrols and their nicotyrines have a general paralysing effect. The pyridylpyrrols have an intensive local anesthetic action on the leg of the decapitated frog and on the sciatic nerve. The acetyl and dibenzoyl- alpha-aminopyridine act as local anesthetics. The blood pressure of the spinal cat is increased by aminopyridine, while the pyrrols show variable effects. On the cat the β-nicotyrine, an oxide of nicotine, diminishes blood pressure, produces convulsions, and in larger doses cardiac standstill.—*H. Graf.*

16090. DOWNS, ARDREY W., and NATHAN B. EDDY. Influence of tyramine on the number of red corpuscles in the circulating blood. *Proc. Soc. Exp. Biol. & Med.* 27 (5): 405-407. 1930.—Tyramine HCl, dissolved in 0.9% NaCl solution, was injected subcut. in single doses (0.1 mgm. to 20.0 mgm. per kgm.), in 4 hourly doses (0.5 mgm. per kgm.), and in daily doses (0.5 mgm. or 5 mgm. per kgm.), in various groups of rabbits. With few exceptions, the red cell count in the circulating blood was increased. In an experiment in which the dose was varied in amount, the percentage increase in erythrocytes roughly paralleled the increasing dose. The effects resembled those obtained by Downs and Eddy by administering secretin to rabbits.

16091. DRAGSTEDT, CARL A., and SEWARD E. OWEN. The mechanism of the diuretic action of secretin preparations. *Amer. Jour. Physiol.* 97 (2): 286-290. 1931. —Experiments on dogs showed that the diuretic effect of secretin preparations is dependent upon their secretory stimulation of pancreatic juice and bile and occurs only when these secretions have access to the small intestine. Secretin diuresis is not dependent upon the integrity of the hypophysis or upon a local specific effect upon the kidney.—*Authors' conclusions.*

16092. DREYER, N. B. Effect of some opium alkaloids on intestinal movements in cats. *Jour. Pharmacol. and Exp. Therapeut.* 36 (3): 477-480. 1929.—The effects of the drugs were studied on the intestine in situ. Papaverine and narcotine produce decreased tone and amplitude. Codeine and morphine cause an increase in both. This effect of morphine is the same on a gut already stimulated by $HgCl_2$ or depressed by intravenous $MgSO_4$ as on the normal gut. Similar results are obtained for the large intestine.—*H. S. Wells.*

16093. DUCRET, S. Die Wirkung von Adrenalin auf die Diastole des Herzens. *Pflüger's Arch. Ges. Physiol.* 227 (1/2): 81-84. 2 fig. 1931.—Tests were made of the effect of adrenalin on the excised rabbit heart perfused through the coronary vessels with Ringer solution. The heart was moderately stretched by a rubber band attached to the apex. Increased force of contraction was noted with adrenalin concentrations exceeding 1 in 100 million, and increased frequency with a somewhat higher concentration. A more effective diastole, induced either by some decrease in tone, or by an increased speed of the diastolic relaxation was observed with concentration exceeding 1 in 100,000.—*H. C. Bazett.*

16094. EDDY, NATHAN B. Regulation of respiration. The effect upon salivary secretion of the intravenous administration of sodium bicarbonate, sodium carbonate, sodium hydroxide, sodium chloride, and sodium sulphate. *Quart. Jour. Exp. Physiol.* 20 (4): 313-320. 8 pl. 1930.—In the dog salivary secretion, elicited by continuous administration of pilocarpine, is decreased by intraven. injection of $NaHCO_3$, of Na_2CO_3, or of NaOH. The decrease in secretion produced by $NaHCO_3$ is greater the larger the dose, and is obtained in like degree whether injected in isotonic or in hypertonic sol. The effect of Na_2CO_3 upon secretion is greater than that of $NaHCO_3$, and the effect of NaOH still greater. Intraven. administered $NaHCO_3$ prevents almost completely the augmenting effect upon salivary secretion of a 10-min. period of re-breathing, though CO_2 accumulated in the re-breathing tank to the same extent as in a similar period of re-breathing without $NaHCO_3$ administration. Each of the 3 alkaline agents increases submaxillary blood-volume flow as a rule. NaCl or Na_2SO_4 intraven. administered in isotonic sol. increases submaxillary secretion and blood-volume flow. Both agents administered in hypertonic sol. decrease salivary secretion but increase more markedly submaxillary blood-volume flow. The effect upon secretion of isotonic and hypertonic sol. of NaCl and Na_2SO_4 appears to be due to the increase in blood-flow and to their influence upon the fluid available to the gland cells by withdrawal of water from the tissues. The described effects of the alkaline substances and neutral salts were obtained with the chorda tympani cut, and were not affected by cutting also the vago-sympathetic. It is suggested that the effects upon salivary secretion of intraven. injection of $NaHCO_3$, Na_2CO_3, and NaOH are due mainly to changes in acid base equilibrium, in which the pH of the interior of the cell may be a major factor. A comparison of the effects of CO_2, of $NaHCO_3$ and of Na_2CO_3 on pulmonary ventilation, mean blood-pressure, and salivary secretion is made.—*Author's summary.*

16095. EDDY, NATHAN B. Regulation of respiration. The effect upon salivary secretion of the intravenous administration of lactic acid, sodium lactate, and hydrochloric acid. *Quart. Jour. Exp. Physiol.* 20 (4): 321-326. 5 pl. 1930.—In the dog the secretion of the pilocarpinised submaxillary gland is increased by intraven. administration of lactic acid and HCl. With the latter the increase in secretion varies in duration and magnitude and is followed frequently by a decrease below the original level. Its effect is the same whether the sympathetic supply to the gland is intact or not. Both agents increase the submaxillary blood-volume flow with the vago-sympathetic intact, but the magnitude of this change seems insufficient wholly to account for the increase in secretion. A similar increase in blood-volume flow is produced after cutting the vago-sympathetic. The increase in secretion produced by lactic acid is greater if the vago-sympathetic has been cut. Sodium lactate, intraven., decreases salivary secretion if the vago-sympathetic is intact but increases it if the nerve is cut. It increases submaxillary blood-volume flow in a like degree whether the vago-sympathetic is intact or not. The differences in the effects of lactic acid and sodium lactate before and after section of the sympathetic supply to the gland suggest a central as well as peripheral control of salivary secretion. The lactate ions appear to be inhibitory to the central and augmentory to the peripheral mechanism of secretion. All 3 agents cause transient changes in blood-pressure, and both of the acids always increase pulmonary ventilation, though the change is generally more transitory than the effect upon secretion. Sodium lactate has no effect upon pulmonary ventilation or decreases it. Again the effect is transient. It is believed that changes in the acid base equilibrium of the tissues and blood are an important factor in the effect upon secretion of lactic acid, of HCl, and of sodium lactate. Coincident changes in blood-volume flow probably affected the results, and some additional effect of the lactate ions, such as their use as food material supplying energy for secretion, may be involved. The act of cutting the vago-sympathetic, while the submaxillary gland was secreting at a constant rate under the continuous injection of pilocarpine, increased submaxillary blood-volume flow sharply but decreased the rate of secretion. Possible mechanisms producing these changes have been discussed.—*Author's summary.*

16096. EDDY, NATHAN B. Regulation of respiration. The effect upon salivary secretion of the intravenous administration of ammonium chloride and ammonium carbonate. *Quart. Jour. Exp. Physiol.* 20 (4): 327-331. 5 pl. 1930.—When the submaxillary gland of the dog is made to secrete at a constant rate by continuous intraven. injection of pilocarpine after cutting the chorda tympani, the administration of NH_4Cl and of $(NH_4)_2CO_3$ produces an initial increase and a subsequent decrease in the rate of secretion. With both agents the initial increase is more marked, and with $(NH_4)_2CO_3$ the sub-

sequent decrease is greater if the vago-sympathetic is also cut before the injection. Both NH_4Cl and $(NH_4)_2CO_3$ increase submaxillary blood-volume flow. With the former the increase is greater with the vago-sympathetic intact; with the latter it is greater with the nerve cut. Both substances in a dose of 1 c.c. per kgm. of M/6 sol. produce a transient fall in blood-pressure and a brief increase in pulmonary ventilation. $(NH_4)_2CO_3$ in a dose of 5 c.c. per kgm. lowers the blood-pressure and depresses pulmonary ventilation, both for a short period only. It is believed that changes in blood-volume flow and in acid base equilibrium are factors in the production of the effects upon salivary secretion of NH_4Cl and $(NH_4)_2CO_3$. Since $(NH_4)_2CO_3$ may turn the tissues alkaline, an additional and stronger action of the NH_4 ion seems indicated. Further, the possibility of modification of the results by the rate of penetration of the ions into the cells is discussed.—*Author's summary.*

16097. **EHRISMANN, O.** Vergleichende Untersuchungen über die intraarterielle und intravenöse Applikation von Giften. *Arch. Exp. Path. u. Pharmakol.* 131 (3/4): 171-185. 1928.—By determination of the lethal dose of local anesthetics, and atropine, codeine, thebaine, Ca and K on guinea-pigs it was found that intraarterial injection is less toxic than intraven. injection. NaCl intracardially injected is not more toxic than when administered intraarterially or intravenously. Suprarenine and para-oxyphenylethanolmethylamine, intraarterially show less activity but this is not due to the higher O content or greater alkalinity of arterial blood. Atropine and nicotine show no difference, when intraarterially injected. As suprarenine and its derivatives are readily adsorbed by charcoal, it is believed that a different distribution, chemical destruction and the adsorption in the tissues may cause the reduced action.—*H. Graf.*

16098. **EICHLER, P.** Klinische und ergographische Untersuchungen über die Wirkung von Harmin und Harmalin bei Postenzephalitikern. *Monatsschr. Psychiatr. und Neurol.* 74 (3/4): 152-163. 4 fig. 1929.—Harmin was given in 22 cases of more or less high-grade postencephalitic parkinsonism, and harmalin in 6 cases. The harmin (especially when given subcut.) had a favorable but transitory effect on voluntary motion and rigidity of the orbicularis, but none on tremor, salivation, seborrhea and myoclonic tics; given by mouth in capsules soluble in the intestine it had slight effect, given in fluid form by mouth, none at all. Harmalin is practically indistinguishable from harmin in its action.

16099. **FALUDI, FRANZ.** Über die Coffeindiurese. *Zeitschr. Ges. Exp. Med.* 62 (1/2): 242-248, 1928.—The effect of caffeine on the proteins of serum and of blood plasma was studied by ultra-filtration through collodion membranes. Caffeine and its derivatives do not increase the ultrafiltrability of blood serum and plasma. The more diluted solutions also do not affect decisively the swelling of gel like colloids; more concentrated solutions are inhibiting. Since the same phenomena may be observed with cane sugar solutions, caffeine diuresis cannot be explained by a reduction of the affinity of the protein for water.—*W. F. von Oettingen.*

[The toxicity of HCN in relation to the partial O tension.] *Sperimentale* 84 (2/3): 115-143. 6 fig. 1930.—The toxicity of HCN was estimated as a function of the partial O pressure and the curve of duration of life as a function of the gas concentration.—*M. L. Menten.*

16103. **FISCHER, HANS.** Der Einfluss der Temperatur auf die Bindungs- und Wirkungsgeschwindigkeit von Digitalisstoffen. *Arch. Exp. Path. u. Pharmakol.* 135 (1/2): 39-81. 1928.—The acceleration of the action of digitoxin on the isolated frog's heart (Straub's method) is independent of the thermal influence upon the normal heart function (rate and excursion), thus providing a method for testing whether a chemical reaction is involved in the digitoxin action. The digitoxin effect is a chemical one, perhaps by fixation of the OH-group of the glucoside, as the action is irreversible. The same is suggested for the action itself, as the thermal coefficient follows Van't Hoff's rule. Bigitaligenin (Cloetta) acts like digitoxin, perhaps chemically; its fixation may be very loose as the reaction is reversible. The lowest effective concentration at 29° C. for digitoxin is 1:400,000; for bigitaligenin at 27° C., 1:25000; at 18° C. 1:250,000 for digitoxin and 1:12000 for bigitaligenin. As the digitoxin effect is irreversible and that of bigitaligenin is reversible, and both follow the Van't Hoff, temp. coefficient, it is suggested that the biological substratum is damaged by the fixation of digitoxin but not by bigitaligenin.—*H. Graf.*

16104. **FISCHL, VIKTOR.** Über die Steigerung der Verträglichkeit und Wirksamkeit von Chemotherapeutika. *Deutsche Med. Wochenschr.* 55 (40): 1663-1665. 1929.—An attempt was made to find an experimental basis for the clinically observed poisonous effects of various agents after the injection of chemotherapeutic substances. Such actions occur with mice but only fatal or non fatal doses may be determined, without producing anything further of significance. One may conjecture, however, that in many cases the reduction of toxicity parallels the reduction in specific-effectiveness. Of the well known established substances, so far, only casein and detoxin, an albuminous synthetic product with many sulphydryl groups, produce a detoxifying effect with the gold preparation solganol. But detoxin simultaneously hinders the therapeutic effect. In experiments on healthy mice and on mice infected with Nagana and recurrent fever, no combined action between neo-salvarsan and other chemotherapeutic agents and poisons could be established.—*V. Fischl (transl. by O. W. Barlow).*

16105. **FLATOW, E., und Y. OSAWA.** Der Einfluss von Wasser auf die Blutgefässe des Frosches. *Arch. Exp. Path. u. Pharmakol.* 140 (3/4): 220-224. 3 fig. 1929.—Water constricts blood vessels perfused with Ringer's solution, acting like a hypotonic NaCl solution. Injection of water into blood vessels perfused with adrenalin constricts them and increases the constrictor action of serum or hypophysin.

16106. **FÖLDES, EUGEN.** Über die Wirkung des Schwefels auf den Kohlenhydratstoffwechsel. *Zeitschr. Ges. Exp. Med.* 60 (5/6): 571-582. 4 fig. 1928.—Inunction of S into the skin of normal rabbits may cause a fall in the blood sugar. In 5 of 6 instances with rabbits that had been treated with inunctions of S the injection of adrenalin produced a hyperglycemia in the usual way. In 1 instance hyperglycemia occurred with death of the animal. Normal rabbits treated for several months with daily inunctions of S and subsequently killed showed an increased glycogen content of the liver, a hyperplasia of the suprarenals and a total, as well as a relative, increase in the S content of the adrenals. Increased glycogen content of the liver and hyperplasia of the suprarenal glands did not occur in those rabbits in

which an extreme hyperglycemia occurred following treatment with S.—*D. Perla.*

16107. FRANCAVIGLIA, ANTONIO. Sul meccanismo dell'iperglicemia da pilocarpina. [On the hyperglycemia produced by pilocarpine.] *Riv. Patol. Sperim.* 5(6): 488-504. 1930.—Hyperglycemia following pilocarpine is due to increased glycogenolysis in the liver, and is accompanied by increased transfer of glucose from blood to tissues. It is checked by atropine. Intravenous administration of glucose leads to a diminution of hyperglycemia from pilocarpine, while the latter is increased by bilateral vagotomy. Bilateral adrenalectomy, though leading to hypoglycemia, does not inhibit the hyperglycemia from pilocarpin, which should be attributed to a stimulation of vagus endings in the liver.—*M. Comel.*

16108. FRANCESCON, A. Ricerche sulla colorazione del polmone in particolari condizioni sperimentali. [Studies on the vital staining of the lung in special experimental conditions.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 533-536. 1930.—Vital staining of the lung was studied following administration of anesthetics (chloroform and aether) by inhalation or direct introduction in the pleural cavity. The histiocyte granulopexis was less pronounced than in the normal.—*M. Comel.*

16109. FRANKE, KURT. Ueber die spezifisch-choleretische Wirkung des Atophans. *Arch. Exp. Pathol. u. Pharmakol.* 151(3/4): 219-231. 6 fig. 1930.—Brugsch and Horsters found that some acid dyes, e.g., eosin, are quantitatively eliminated with the bile. During 8-10 hrs., cats and rabbits received intravenously 2 cc. of a 1% eosin sodium solution once every 30 min., the dogs also intravenously received 5 cc. of a 2% eosine sodium solution once an hour. After the extraction of bilirubin and biliverdin with a 20% $CaCl_2$ solution and alcohol the dye was measured by comparison with a standard likewise prepared. In the dog, cat and rabbit atophan and atophanyl in small doses increase the excretion of eosin to about triple the norm without raising the amount of bile. Larger doses of atophan produce an increase of bile with diminished dye contents. This dilution of the bile, measured by the increase in quantity produced, can be considered as an index of the hepatotoxic action of large doses of atophan. Decholine raises the bile quantity with a constant relation between the bile and the dye. A parallelism between the acceleration of diffusion of the dye from serum to gelatine and the specific choleretic effect was noted.—*H. Graf.*

16110. GERLÓCZY, GÉZA, und GÁBOR BERENCSY. Die Resorption des in physiologischer Kochsalzlösung peroral verabreichten Calciumchlorid. I. *Zeitschr. Ges. Exp. Med.* 73(5/6): 711-714. 1930.—Aqueous 10% solution of $CaCl_2$ orally given in doses of 0.15 gm. per kgm. raised the blood Ca in 4 clinical cases 0.62-1.9 mgm. % (ave. 1.36 mgm. %) in ½-1 hr., the increase subsiding in about 7 hrs. $CaCl_2$ in physiologic NaCl solution under like conditions raised the blood Ca much more—in some cases by 170%, (ave. 143%) of the normal value.

16111. GESSNER, O., und K. SIEBERT. Zur Chemotherapie der Tuberkulose. (Beeinflussung der experimentellen Meerschweinchentuberkulose durch Mangan- und Berylliumsalze.) *Beitr. Klin. Tuberk.* 75(5/6): 609-612. 1930.—Small doses of $MnCl_2$ or $MnCl_2+BeCl_2$ administered to tubercle infected guinea pigs together with tuberculin-like substances produced a transient favorable influence upon the tuberculous process. Large doses of these salts affected the tuberculous process unfavorably. These results are considered as confirmatory rather than opposing Walbum's findings, emphasizing the importance of correct dosage in the therapeutic application of metallic salts in tuberculosis.—*Author's summary (transl. by M. I. Smith).*

16112. GESSNER, OTTO. Über Uzara. I. Über die digitalisartige Wirkung der Uzaraglykoside auf das Herz. II. Über den Wirkungsmechanismus von Uzara bei glattmuskeligen Organen, insbesondere am Darm. *Arch. Exp. Pathol. u. Pharmakol.* 148(5/6): 342-352. 2 fig.; 353-368. 5 fig. 1930.—I. Uzara acts like digitalis in some respects and like saponin in others. Uzara derivatives having digitalis action are the crystalline glucoside uzarin, the microcrystalline glucoside uzaren, and to a somewhat less extent the aglycone of uzarin, uzaridin. The water soluble split products, anhydrouzaridin and uzarenin, did not have any digitalis-like action on the heart. The cardiac effect of uzara glucosides in comparison with g-strophanthin is so slight that with oral administration it is only a side action. II. The effect of uzara on various smooth muscles was studied, including the stomach rings and cloaca of frogs, small intestine and rectum of guinea pig and rat, ductus deferens of the guinea pig, strips of blood vessels from warm blooded animals, perfused frog's hind legs, and in addition nerve-free tissue,—the chick amnion. Uzara had a direct action on contractile substance. The uzara glucosides in weak concentrations stimulated contraction, in high concentration produced reversible paralysis of smooth musculature. The mother-liquor of a uzaron-tannin precipitate (free from uzarin, uzaren, or uzaridin) produced a reversible paralysis in smooth muscle. Uzara, furthermore, increases the irritability of the endings of the sympathetic nerves. This action on the sympathetic could possibly be used in therapeutics.

16113. GESSNER, OTTO, und F. J. SCHLENKERT. Über Neodorm. *Zeitschr. Ges. Exp. Med.* 73(5/6): 586-598. 1930.—For white mice (46 mice) the minimal lethal dose per kgm. subcut. is for neodorm, 0.265 gm.; for chloral hydrate, 0.42 gm.; for ethyl alcohol, 8.25 gm.; therefore, on the mouse, neodorm is 1.6 times more active than chloral hydrate and 30.6 times more active than ethyl alcohol. The m.l.d. of neodorm for the frog after injection into the lymph sac lies between 0.1 and 0.33 mgm. per gm. For (255) salamander larvae, the fatal conc. of neodorm is 1:700; for chloral hydrate, 1:100; for ethyl alcohol, 1:20. The paralyzing concentration of neodorm (for salamander larvae) is 1:26000; of chloral hydrate, 1:750; of ethyl alcohol, 1:90. The just effective concentration of neodorm (for salamander larvae) is 1:50000; of chloral hydrate, 1:1000; of ethyl alcohol, 1:200. From these figures, it is obvious that neodorm has a marked "therapeutic breadth"; (paralyzing-fatal threshold concentration quotient) 4 times greater than chloral hydrate and 8 times that of ethyl alcohol. In comparison to chloral hydrate and ethyl alcohol the "total activity breadth" (just effective-fatal concentration threshold quotient) of neodorm is 7-fold. Distinct signs of excitement which may culminate in convulsions; occur in the mouse after neodorm, in the amphibian larvae, excitement was not observed; on frogs, seldom. In the mouse during the hypnotic stage, the respiration is at first slowed but deepened; dyspnea occurs later; and, after lethal doses, cessation of respiration. On all types of animals used, the influence of neodorm on the circulation, especially the heart, is very slight. On isolated frog organs (skeletal muscle (52); motor nerve and heart (61)) neodorm has greater absolute activity than chloral hydrate and ethyl alcohol; but, in comparison to narcotic action on the central nervous system, has so little effect that, practically, "side actions" on these organs, especially the heart, scarcely come into consideration. The cardiac action of neodorm (reduction of systole; after larger doses, diastolic stand-still) is easily reversible; the neodorm stoppage of the heart can not only be quickly and completely overcome by Ringer's sol., but, after more prolonged action of neodorm on the heart, recovery can be effected by suprarenin. Neodorm action shows itself to be dependent on temperature in accordance with the rule determined by H. H. Meyer, so that with increasing temperature and simultaneous increase in partition coefficient the narcotic activity increases. (33 salamander larvae) On (20) salamander larvae, after continued employment, "habituation" occurred; the cause of this has not yet been discovered.—*Author's summary (transl. by C. C. Haskell).*

16114. GIACOMO, UMBERTO de. Primi dati sull'azione catatonizzante, nell'uomo, di un alcaloide a struttura etil-amino-ciclica (la bulbo-capnina). [The cata-

tonic action on man of an alkaloid with ethyl-amino-cyclic structure, bulbocapnin.] *Boll. Soc. Ital. Biol. Sperim.* 5(4) : 501-504. 1930.—Bulbocapnin may provoke catatonia and mental confusion.—*M. Comel.*

16125. **HANZLIK, P. J., and H. G. MEHRTENS, (with the assistance of D. C. MARSHALL, FRANCES WATSON, and JEAN SPAULDING). Clinical excretion of bismuth: bismuth sodium tartrate.** *Arch. Dermatol. & Syphilol.* 22(5) : 850-860. 1930.—The urinary excretion of Bi after different doses of the soluble Bi-Na tartrate (73.8% Bi) in aqueous medium was studied in 11 human subjects 4 of whom had edema of cardiac origin. The excretion in the subjects with edema did not differ materially from that in subjects without edema. The excretion was characterized by a prompt onset, early peak or maximum, comparatively short duration, without marked individual variation, thus differing in several respects from insoluble products and those given in oil. Bismuth was invariably present in the day following administration, indicating rapid absorption; the peak or maximum daily excretion occurred on the 2nd day, and the excretion lasted about 13 days (median) after single doses, equivalent to 0.022 gm. of Bi. The results were similar after 2 and 3 single doses. Those after 7, 9 and 17 successive doses showed a delayed peak, and the data on duration were incomplete. After single doses, the median amount of Bi excreted from day to day was about 1 mgm., and at the end of 2 wks., was a median total of 45.2% of the total administered. The total excretion after 2 doses, or 0.044 gm. Bi, was about the same, the results after repeated doses representing higher total dosage, namely 0.066, 0.2, 0.31 and 0.52 gm. of bismuth, being incomplete. The total excretion of Bi after the highest doses used (0.2 gm. and over), as also the daily maximum of Bi excreted, did not increase in proportion to the increase in dosage, but, on the contrary, decreased, confirming a similar tendency observed in the excretion of Bi after the injection of Bi (metal), previously reported. This agreed with a similar phenomenon after the use of toxic and fatal doses in animals, reported in the literature. The possible significance of this is discussed. The excretion of Bi occurs mainly in urine, since the excretion in the feces of 2 subjects receiving 3 and 4 single doses of Bi-Na tartrate was found negligible at different periods; the highest daily amounts detected were about ½ to ¼ of those in urine on the same days. This general result agrees with those on the insoluble and oil-suspended products. In general, the intramuscular injection of soluble Bi-Na tartrate results in the prompt absorption, distribution and uniform excretion if Bi. Thus, a prompt saturation of the tissues may be expected. With repeated, intensive medication, accumulation of Bi will supervene owing to the slowing down of excretion. The rapid removal of Bi indicates the necessity of more frequent injections, but these should be used with suitable rest periods to avoid harmful accumulation. Presumably, the muscular depots after Bi-Na tartrate are negligible, although Bi continues to be excreted in urine for days in amounts too small to be estimated, but probably not as long as after the insoluble and oil-suspended products. —*Authors' conclusions.*

16126. **HARA, Y. Experimental studies on the poisons of Formosan snakes. The influence of the snake poisons on the resistance of the red blood corpuscles, on the velocity of sedimentation of the red blood corpuscles and on the blood coagulability.** *Taiwan Igakkai Zasshi [Jour. Med. Assoc. Formosa]* 306. 50-51. 1930.—In the hemotoxic types of venom the resistance of the r.b.c. was markedly decreased, but in the neurotoxic type there was no change. Sedimentation of the corpuscles was accelerated, more strikingly in the hemotoxic type. Clotting is delayed in the presence of hemotoxic venoms. These characters are of differential clinical importance. —*E. C. Faust.*

16127. **HARDING, VICTOR JOHN, and L. J. HARRIS. Urea administration in water intoxication.** *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 101-110. 1930.—The retention of water to produce convulsive symptoms of water intoxication in dogs must be over 60 cc. per kgm. The critical value appears to be from 60-70 cc. per kgm. All animals in water intoxication convulsions recovered by the administration of 10% NaCl. Only 2 animals out of 14 recovered from water intoxication convulsions by the administration of hypertonic urea solutions. It is doubtful if the convulsions of epilepsy or eclampsia are manifestations of "water intoxication" even though they may be accompanied by a positive water balance.—*V. H. Harding.*

16128. **HEATLY, CLYDE A., and SAMUEL W. CLAUSEN. Experimental studies in peanut bronchitis.** *Arch. Otolaryngol.* 11(5): 569-579. 4 fig. 1930.—Bronchitis caused by peanut aspiration has been called arachidic bronchitis from the scientific name of the peanut *Arachis hypogaea.* Arachidic bronchitis is due to irritation; infection plays only a secondary rôle. Fat-free residue of peanuts containing unaltered proteins and carbohydrates produced no reaction. The irritant is an acid present in both the oleic and linolic fraction, and absent in the solid fraction of the fatty acids. Peanut oil containing free fatty acids is irritating. Peanut oil deprived of free fatty acids was not irritating. As small a concentration of .3% of free acid in an oil will produce irritation. Experiments were performed with rabbits. Typical arachidic bronchitis could be produced in them.

16130. **HENRIJEAN, F., et R. WAUCOMONT. Recherches sur l'action cardiaque de l'ergotamine.** *Arch. Internat. Pharmacodynamie et Ther.* 38: 618-832. 1930. —The irritability of the vagus is not augmented by the action of ergotamine. Stimulation of the ansa of Vieussens is effective up to a late stage of poisoning, while stimulation of the vagus produces a definite arrest of the heart. The mechanism of this arrest is not elucidated and is not in all cases due to paralysis of the accelerator endings. The injection of adrenalin during the cardiac arrest leads to cardiac contractions which are shown by the electrocardiogram to be of heterotopic origin.—*F. Henrijean (transl. by O. Barlow).*

16131. **HENRIKSSON, HARALD E. Zur Kenntnis der Einwirkung des Tabakrauchens auf den Kreislauf.** *Skand. Arch. Physiol.* 60(1/4): 143-188. 1 fig. 1930.—Large volumes of tobacco smoke were administered to 15 rabbits. The frequency of heart beat was decreased. The min. vol. decreased for a short time then increased above normal. The blood pressure showed a slight primary fall followed by a stronger, secondary rise. The work of the heart was often increased markedly.—*Author's summary (transl. by J. C. Munch).*

16132. **HENRY, GEORGE W., and HERMAN de JONG. A comparative study of the action of bulbocapnine and some other drugs in producing catatonic states.** *Acta Psychiatr. et Neurol.* 5(4): 463-471. 1930.—In an investigation of experimental catatonia induced in animals by subcutaneous injections of bulbocapnine the authors have desired to determine whether similar states follow the administration of certain other drugs. Illustrative experiments only are reported, from unspecified series with cannabis indica, harmin, luminal, sulphonal and somnifen on the hen, duck, cat, mouse and dog. The experiments show that with the exception of cannabis indica none of the drugs studied produce reactions similar to those induced by injections of bulbocapnine. Cannabis indica causes the animal to become drowsy, less active, rather indifferent to natural enemies, and to lose desire for food and drink. Occasionally it produces drooling and a tendency to maintain awkward postures. In large doses it produces disturbances of equilibrium, swaying movements on standing or walking, ataxia and action tremors of the extremities. Injections of harmin in small doses also cause drowsiness and reduction of general activity while in larger doses they cause generalized tremors, hyperexcitability, hypertonicity and spasms and finally tonic-clonic convulsions. Occasionally an animal intoxicated by this drug shows a tendency to withdraw to a dark corner of the room. The ordinary sedative drugs in small doses produce only drowsiness and sleep while in larger doses they produce disturbances of equilibrium and ataxia as well as the hyperkinetic phenomena characteristic of large doses of motor excitants. The reactions to cannabis indica somewhat resemble the loss of motor initiative, drooling and catalepsy produced by injections of bulbocapnine. Although the closest approximation to the action of bulbocapnine was obtained with cannabis indica the catatonic-like manifestations were only occasionally and imperfectly developed. Henry and de Jong never saw negativism and complicated hyperkinetic symptoms after administration of cannabis indica. These symptoms are very striking after bulbocapnine intoxication.

16133. **HERTEL, E. Über die Bedeutung der Ehrlich'schen Fluoresceinversuche.** *Arch. Augenheilk.* 100/101: 460-469. 1929.—Experiments on rabbits show that a movement of liquid produced by change of osmotic pressure in the blood can be recognized by measurement of the eye-pressure and, at the same time, can be well shown in the fluorescence experiment. Movements of both fluid and fluorescein, proceed in the same direction. Marked osmotic changes in the blood increase the penetration of liquid and dye into the vessels. By equalization of the osmotic differences, the discharge of both is lessened or abolished. An influx of liquid and fluorescein out of the vessels into the eye then takes place. Therefore, the entrance and return of liquid and dye results according to physical laws, such as are already well known for interchanges between blood and tissue.—*E. Hertel (transl. by E. V. Lynn).*

16134. **HICKMANS, EVELYN M., and SYDNEY H. EDGAR. The blood constituents in acute rheumatism before and after salicylate treatment.** *Arch. Dis. Childhood* 5(30): 387-396. 1930.—Three cases before salicylate treatment was commenced showed blood urea, non-protein N and uric acid somewhat higher than in normal children of the same age. Although salicylate increases the urinary output of total N, urea and uric acid, and the blood uric acid is thereby decreased, the examination of many cases indicates that the blood urea and non-protein N still remain slightly above normal during treatment. Since the blood P is also slightly above normal, it would seem that the kidney in rheumatism is unable to deal adequately with these 2 products. That this is due to some impairment of renal efficiency as a result of the acute rheumatic infection rather than to the salicylate, is suggested by the fact that the blood urea of normal children was not increased by similar quantities of salicylate. On the other hand, considering that after salicylate treatment, blood urea reaches a higher level than before salicylate is given, salicylate may possibly increase to some extent the degree of renal inefficiency.—*Authors' summary and conclusions.*

16135. **HILAROWICZ, HENRYK. Über die Somnifen-Urethan-Magnesium-Einschläferung bei chirurgischen Operationen.** *Schmerz* 2(12): 443-451. 1930.—Somnifene contains in 1 cc. of solution .1 gm. allyl-iso-propyl-barbituric acid and .1 gm. di-ethyl-barbituric acid. The effect

of this anesthetic was tried on 3 healthy dogs recording carotid blood pressure and respiratory movements. Somnifene in doses of .23 cc. per kgm. body weight lowered blood pressure about 30%. Urethane and $MgSO_4$ lowered it somewhat, but not so markedly. A mixture of urethane, somnifene and $MgSO_4$ produced nearly as great a blood pressure lowering as somnifene alone. Somnifene alone produced marked changes in the respiration. It produced a sleep of short duration followed by considerable pain. Mixtures of .44 cc., somnifene, .3 gm. urethane and .03 gm. $MgSO_4$ per kgm. produced a deep sleep in both dogs and men. After 7-8 hours in dogs and somewhat sooner in men, awakening occurred, followed generally by no ill effects. Three out of 33 human cases on which this anesthetic was used died during or shortly after operation, but the condition of the patient and the trauma due to operation might have been the cause of death, rather than the anesthetic.

16136. **HIRATA, TATSUJIRO. Über den Einfluss der Ermüdung auf die Wirkung der Arzneimittel. III, IV, V.** *Kyoto Igaku Zasshi* (*Kyoto Med. Jour.*) 25: 16-22, 401-407, 799-803. 1928.—There is no striking difference between the resistance to morphine of nervous tissue in an animal fatigued by work and in one which has rested. The resistance of the nervous tissue of tired and hungry animals was less than in those which rested during the fasting period. The resistance of nervous tissue of tired and hungry animals to narcopon-scopolamine, and to pantopon-scopolamine, appears to be surprisingly decreased.

16137. **HIRSCHFELDER, ARTHUR D., and ELMER T. CEDER. Does ethylene affect rate of growth or action of enzymes in animals?** *Amer. Jour. Physiol.* 91(2): 624-636. 2 fig. 1930.—Exps. showed no stimulating effect on the growth of rats by drinking water saturated with ethylene (14 exp. rats, 13 controls), or by inhaling over long periods air containing 1% (11 exp. rats, 11 controls), 0.1% (12 exp. rats, 12 controls) or 0.01% (15 exp. rats, 15 controls) of ethylene. The growth of rats is therefore not favorably affected by ethylene in 10 times the concentration which activates ripening of plants. Exps. in vitro indicate that saturation with ethylene does not convert starch into sugar as claimed by Rea and Mullinix (though it does increase the activity of amylase) nor does it affect the activity of pepsin, trypsin or liver lipase. No marked effect in the reversal of lipase action was noted, i.e., the synthesis of ethylbutyrate from ethyl alcohol and butyric acid.

16138. **HIRSCHFELDER, ARTHUR D., J. B. ENEBOE, and R. L. PARSONS. Antagonization of anesthetic effect of magnesium sulphate by chlorides of potassium, rubidium and sodium.** *Proc. Soc. Exp. Biol. & Med.* 26(3): 258-259. 1928.—Preliminary paper.

16139. **HOLOBUT, WIESLAW. Action de la strychnine sur les nerfs moteurs et influence des ions alcalins.** *Compt. Rend. Soc. Biol.* 100(14): 1232-1233. 1929.—Strychnine sol., applied directly to the sciatic nerve, caused a marked and steady increase of excitability to a maximum. Li and K salts increased the effect and those of Ca, Ba, and Mg caused a slow but steady decrease in the effect of the strychnine. Strychnine tends to cause a greater permeability of the cell membrane and has a specific action on albumin, probably causing it to swell.

16140. **HOLTZ, FRIEDRICH, und EMMA SCHREIBER. Einige weitere physiologische Erfahrungen über das bestrahlte Ergosterin und seine Umwandlungsprodukte.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 191(1/2): 1-22. 1 pl., 9 fig. 1930.—As a result of apparently extensive experiments on dogs, rabbits and other animals, the authors conclude: The poisoning with irradiated ergosterol which has been designated by many authors as hyper-vitaminosis is not due to the administration of an excessive dose of vitamin D but is a consequence of the administration of a "calcinose factor" which is formed during the irradiation. The quantitative relationship between the concentration of vitamin D and the "calcinose factor" appears to vary within narrow limits, whether one irradiates with Mg spark or with a mercury vapor light with or without filters or whether one alters the solvent or the time of the irradiation. Only in this way can one explain why in a rather superficial evaluation of the antirachitic and toxic minimal dose a parallelism between these two properties has been observed by numerous investigators. No one has as yet succeeded in producing a potent antirachitic but non-toxic preparation and one can, therefore, state as a 2nd finding of this work that as a result of the ultra-violet irradiation there is formed from ergosterol a chemical compound which simultaneously presents both antirachitic and Ca raising properties (the "calcinose factor"). By means of certain chemical processes such as heating and careful hydrogenation this ergosterol derivative is so changed that the antirachitic effectiveness disappears but the toxicity which is dependent upon another atomic group remains.—*Authors' conclusions* (*transl. by B. Kramer*).

16141. **HORSTERS, HANS, und HANS ROTHMANN. Über den Einfluss peroral zugeführter Gallensäuren auf den Zuckerstoffwechsel des Diabetischen.** *Arch. Exp. Path. u. Pharmakol.* 142(3/4): 261-270. 1 fig. 1929.—By oral and intraven. administration of bile acids (cholalic, desoxycholalic and dehydrocholalic acids) and their salts, a marked decrease in fasting blood sugar was obtained in normal and diabetic patients [4 normal and 10 diabetic cases are cited]. In diabetics this fall in blood-sugar exceeded the drop caused by hunger alone. The course of the blood-sugar curve after administration of biliary acids in some cases corresponded to the fall in blood-sugar produced by insulin. The rise in blood-sugar regularly occurring in diabetics after taking food was prevented by oral administration of bile acids. In mild cases of diabetes an improvement in carbohydrate tolerance was obtained by peroral administration of bile acids; frequently no effect was produced in severe cases. Apparently the mechanism of the action of bile acids on carbohydrate metabolism is based on a stimulation of pancreatic tissue still capable of functioning.—*Authors' summary* (*transl.*).

16142. **HOUSSAY, B. A. Clasificación de las acciones de ponzoñas de serpientes sobre el organismo animal.** [Action of snake venoms.] *Rev. Soc. Argentina Biol.* 6(5/6): 351-357. 1930.—The following classification is proposed: I.—Toxic action, a) curarising, *Naja tripudians* type; b) Neurotoxic, *Crotalus terrificus* type; c) shock, *Lachesis* type; d) mass blood clotting, *Vipera ruselli* type.—II.—Action due to phosphatidase, a) hemolytic; b) anticoagulating; coagulating; c) cytolytic.—III.—Action of protease, local irritation and hemorrhagic, a) tumefaction, hemorrhage and local necrosis, secondarily anaerobic bacteria flourish, *Lachesis* type; b) Hemorrhagic pancreatitis and steatonecrosis by injection in the pancreatic duct; c) hemorrhages distant from site of injection; d) decrease in circulating fibrinogen, *Crotalus adamantens* and *L. flavoviridis* types. —IV.—Coagulating and thrombinic action, a) intravascular clotting by a thrombin different from the usual blood thrombin, when large doses are given; b) positive phase followed by negative phase when small doses are injected due to decrease in fibrinogen owing to gradual precipitation, *Lachesis* type; c) increase in globular resistance; d) increase in sedimentation time; e) intense initial shock; f) increase in blood globulin, decrease in albumin and fibrinogen, decrease in total protein of blood.—*J. T. Lewis.*

Japonica* 3: 1581-1590. 1928.—After injection of quinine in rats the thyroid and the hypophysis were examined histologically. The thyroid showed the picture of colloid goiter, whether due directly or indirectly to the quinine the author could not decide. The anterior lobe of the hypophysis showed an increase and enlargement of the eosinophile cells and hyperemia, probably compensatory processes.

16144. **INAMI, TAKEHIKO. Über den Einfluss der Schwangerschaft sowie des Kalium- und Calciumgehaltes**

der Nährflüssigkeit auf die Wirkung der Uterustonica. *Chiba Igaku Kwai Zasshi (Mitteil. Med. Ges. Chiba)* 6: 67-184. 1928.—The action of various drugs on the spontaneous pendulum movement and the tonus of the excised uterus, nonpregnant and pregnant, was tested in normal Locke's sol. and in that containing either excess or deficiency of K or Ca. Rabbits and guinea pigs were used; they showed about the same sensitivity to pituitary extract, chloral hydrate, quinine, secacornin, pilocarpine, and atropine as well as to K and Ca ions. Epinephrine had a stimulating action on the rabbit uterus, an inhibiting one on the guinea pig. The guinea pig uterus was much more sensitive to cocaine, which affects the sympathetic in the manner of epinephrine, than was the rabbit uterus. The uterine action of drugs which affect the uterine musculature itself—quinine, secacornin, cocaine, etc.—was increased by pregnancy while that of the so-called parasympathetic drugs—pilocarpine and atropine—was not influenced. The uterine action of drugs of endocrine nature was most distinctly influenced by pregnancy. Epinephrine and pituitary extract had a stimulating action on the nonpregnant uterus; both lost their effectivity at the beginning of pregnancy; the action reappeared later to reach its peak at the end of pregnancy or during the puerperal period. The stimulation of uterine contractions by the various drugs was weakened by excess of K ions and increased if they were decreased or absent. The stimulation of the uterus due to drugs was increased by excess of Ca ions; if they were entirely absent pituitary extract, quinine, secacornin, and atropine produced no stimulation. Epinephrine, pilocarpine, and cocaine could produce stimulation when Ca ions were absent and if the dose were sufficient it appeared that these drugs could replace the Ca action.

Pharmacol.* 38(2): 71-76. 1931.—Experiments show that the mercurimetric method can be applied with success for determining spartein, novocain, stovain and plasmochin.

16146. **JANSSEN, S., u. A. LOESER. Hypophysenvorderlappenpulver und Ovarium. II. Die quantitative Auswertung der Wirkung.** *Arch. Exp. Path. u. Pharmakol.* 151(3/4): 188-196. 1 fig. 1930.—Using a dried powder of the anterior lobe of the pituitary, that possesses, qualitatively, the complete activity upon the ovary, it is possible to construct a characteristic curve showing the relationship between dosage and percentage of positive results in groups of 10 rats. This curve can be used for evaluation of the gland products or of pregnancy urine. Glands of cattle dried with acetone and preserved over P_2O_5 have almost the same value as freshly transplanted glands.

16147. **JENSEN, H., and K. K. CHEN. Chemical studies on toad poisons. Ch'an, the dried venom of the Chinese toad.** *Jour. Biol. Chem.* 87(3): 741-753. 1930.—From Ch'an Su, the following compounds have been isolated: (1) epinephrine; (2) cholesterol; (3) suberic acid; (4) a pressor principle, different from epinephrine, in the form of a flavianate; it seems to be closely related to or identical with the pressor principle isolated by Handovsky from *Bufo vulgaris*. (5) Cinobufotoxin, which seems to be chemically closely related to bufotoxin, isolated by Wieland and Alles from *Bufo vulgaris*. On hydrolysis with HCl a decomposition product of cinobufagin which could not be crystallized, suberic acid, and arginine were obtained. (6) Cinobufagin, which was found to be different from bufagin isolated by Abel and Macht from *Bufo marinus*. The pharmacological action of cinobufotoxin and cinobufagin was quite similar to that of the digitalis glucosides. From the mother liquor obtained in the preparation of cinobufagin, a Cl-containing body was prepared. Contrary to Kotake, who assumed that this substance was derived from cinobufagin, the authors believe that it is a derivative of bufotalin. The latter has been isolated by Wieland and his coworkers from *Bufo vulgaris*.—*Authors' summary.*

16148. **JENSEN, H., and K. K. CHEN. Chemical studies on toad poisons. 3. The secretion of the tropical toad, Bufo marinus.** *Jour. Biol. Chem.* 87(3): 755-759. 1930.—From the secretion of the "paratoid glands" was isolated in crystalline form a N-containing substance which is named marinobufotoxin. It seems to be closely related chemically to bufotoxin and cinobufotoxin; its elementary composition is $C_{42}H_{62}O_{11}N_4$. The pharmacological action was quite similar to that of cinobufotoxin. Bufagin was also prepared and found to be identical with the bufagin isolated by Abel and Macht. It has the composition $C_{28}H_{36}O_6$. A monoacetyl derivative of bufagin having the composition $C_{30}H_{38}O_7$ was prepared. —*Authors' summary.*

16149. **JENSEN, JULIUS. Clinical studies on cardiovascular response to adrenalin administered subcutaneously.** *Proc. Soc. Exp. Biol. & Med.* 26(3): 259-260. 1928.—Preliminary paper.

16150. **KAHLSON, G., und R. v. WERZ. Über Nachweis und Vorkommen gefässverengernder Substanzen im menschlichen Blute.** *Arch. Exp. Pathol. u. Pharmakol.* 148(3/4): 173-197. 9 fig. 1930.—The blood vessel preparation of Krawkow-Pissemski was used as a test object. The sensitivity to constrictors was very high; the average adrenalin sensitivity (from 84 preparations) was $1:10^9$. Changes in sensitivity of the blood vessel preparation after citrate and serum perfusion solution were used on them did not occur. The specificity of the method for adrenalin could be demonstrated since ergotoxin antagonized the effect of adrenalin but not of nonspecific vasoconstrictors. Extravascular adrenalin action was not a grave source of error since in dilutions of $1:2\cdot10^8$ to $1:10^9$ the average activity lost was only 1.20% per min. Dilution of citrated blood 10 times did not affect the sensitivity of the preparation. Blood from hypertonus thyroid toxin patients and fever patients had a greater vasoconstrictor effect than blood from normal people.

16151. **KAIRIUKSCHTIS, VLADAS. Versuche mit Neon-, Argon- und Heliothorax bei Kranken an Lungentuberkulose.** *Zeitschr. Tuberk.* 59(5): 339-346. 9 fig. 1931. —In 1 patient air, A, Ne, and He were injected successively into the pleural cavity; in the 2nd, N and Ne. Resorption was followed from roentgenograms, using a planimeter; Ne and He persisted longest; A was more rapidly resorbed than air; Ne persisted longer than N.

16152. **KALK, HEINZ, und KARL NISSEN. Experimentelle Untersuchungen über die Wirkung des Spinatsekretins (Sekreton).** *Arch. Verdauungs. Krankh.* 49 (3/4): 129-143. 1931.—Injections of 2 cc. of secreton in man produced no drop in blood pressure; wheals similar to those from histamine occurred on subcut. injection. Observation of the peritoneum with the laparoscope in 3 men after intramuscular injection of 2 cc. and 8 observations with the capillary microscope in the open abdomen of 2 cats and 3 rabbits after 1 cc. intramusc. showed that the action of secreton on the small vessels was the same as that of histamine, but weaker. It produced as strong contractions in the isolated gallbladder and intestine of the guinea pig as did histamine. Subcut. and intramusc. injection of 2 cc. in man (26 exps., 18 persons) and 1 cc. in 2 dogs stimulated gastric secretion and acidity. As with histamine, achylia can be differentiated with secreton. It appeared to attack the gland cells of the gastric mucosa directly.

16153. **KATAGI, RYUZO. Der Einfluss einiger erregender Gifte auf die Wirkung des Tetrodotoxins am Skelettmuskel.** (Japanese.) *Okayama Igaku Kwai Zasshi* 39: 1869-1880. 1927.—Tetrodotoxin is a drug isolated by Tawara from the ovaries of a poisonous Japanese fish. This investigation reveals that it has a curare-like action on skeletal muscle and a paralysing effect on the respiratory and vasomotor centers. According to Hayashi and Muto's findings, who investigated the respiratory standstill, it appears that the drug acts by a curare-like paralysis of the phrenic. The author set out to investigate these previous conclusions and found that besides this curare-like action, it has a strong action on the

skeletal muscle, and is antagonistic to some of the stimulating drugs. The work was performed on isolated nerve-muscle preparations of *esculanta* and the following results were obtained: Guanidine, strychnine, caffeine, camphor, strophanthin and adrenaline lower the indirect stimulant effects on skeletal muscle following tetrodotoxin, and depress this action to some extent. This antagonistic action of the above-mentioned drugs is effected in different ways—adrenaline acts by stimulation of the motor nerve endings, strychnine, caffeine, and camphor on the contrary act on the muscle alone, and very probably guanidine and strophanthin act through both sites. The antagonism of quinine and tetrodotoxin reported by others was not seen. The drugs which can arrest the muscle paralysis following large doses of tetrodotoxin, are limited to the muscle stimulators, as caffeine, camphor and strophanthin. In a muscle almost entirely paralyzed by large concentrations of tetrodotoxin, the first two were especially active antagonists.—*Author (courtesy Jap. Jour. Med. Sci. IV) (transl. by H. C. Lueth).*

16154. [KAZANSKIĬ, V. I.] КАЗАНСКИЙ, В. И. Механизм лимфоцитоза после спленектомии. [Mechanism of lymphocytosis after splenectomy.] Клинический Журнал Саратовского Университета (*Klin. Zeitschr. Univ. Saratow*) 7(3): 227-248. 1929.—The author tested Schultze-Berezow's theory of the paralyzing influence of the lieno-hormone upon the parasympathetic system. Two men with healthy spleens were used as controls; 6 patients were experimented upon before and after splenectomy. In healthy subjects and those before operation, lability of lymphocytes toward atropine fluctuates between −0.7 and −19.5%; after splenectomy between −32.5 and −50.5%. This is a refutation of Wollenberg's statement as to the indifference of the lymphoid organs toward atropine. Lability of lymphocytosis toward pilocarpine in non-splenectomized subjects is +32.8% to +87.5%; in splenectomized subjects at the end of 1 month it is +38%; at the end of 2-3 months it is +8% to 0%. Splenectomy created experimental vagotonics.—*B. Van Rosen.*

16155. **KEHAR, N. D. Some aspects of the behavior of cinchona alkaloids towards living cells. Part II. Penetration of the various cinchona alkaloids into colloidal cells. Part III. The effect of plasmoquine on the penetration of the cinchona alkaloids.** *Indian Jour. Med. Res.* 18(1): 203-220. 1 pl. 1930; (3): 987-1011. 3 fig. 1931. —An investigation of the penetration of the cinchona alkaloids into living cells and their chemical analogues in the presence of various electrolytes showed that the presence of acids and alkalies accelerates the penetration, while the neutral salts are generally without any effect, the stronger acids and alkalies allowing more penetration than the weaker ones. In the mono- and di-basic acid series the range of penetration of the alkaloids is related to their chemical nature and systematic position in the homologous series. The degree of penetration of these alkaloids seems to be approximately an index of their clinical value in malaria. If plasmochin is mixed with the cinchona alkaloids under the above conditions, the penetration of the alkaloids is considerably increased and is very much in excess of what could be expected according to the Mixture Law. The better clinical effects recorded in malaria after treatment with plasmochin and quinine might be due to the greater and quicker penetration of the two drugs either by enhanced absorption or increased parasiticidal action. Cinchonine chloride in combination with plasmochin penetrates more than quinine under similar conditions, and if penetration is any index of clinical value, the drug is worthy of a trial. An improved form of conductivity cell is described.—*N. D. Kehar.*

16156. **KEHOE, ROBERT A., and FREDERICK THAMANN. The behavior of lead in the animal organism. II. Tetraethyl lead.** *Amer. Jour. Hyg.* 13(3): 478-498. 3 fig. 1931.—Experiments on about 38 healthy rabbits show that tetraethyl lead [$Pb(Et)_4$] is absorbed through the skin. The initial distribution of the Pb in the tissues is rapid. $Pb(Et)_4$ absorption corresponds to that of an oil-soluble material, and indicates therefore that some portion of it is absorbed and circulates as such. However, $Pb(Et)_4$ is rapidly decomposed by the tissues, including the skin, so that only a small portion of the Pb found later in the blood is in the original form. As a result, after 3-14 days all the Pb in the tissues is distributed in a manner characteristic of water-soluble Pb compounds. In small dosages the factors of rapid decomposition and low concentration in the blood so interfere with the distribution of $Pb(Et)_4$ as such, as to prevent its primary absorption by the nervous system. Even when absorbed as the Et_4 compound, the excretion follows quantitatively that of water-soluble Pb compounds. $Pb(Et)_4$ poisoning is therefore not different from Pb poisoning occasioned by other Pb compounds. Evidence is adduced showing that $Pb(Et)_4$ absorption from gasoline in concentrations not in excess of 0.1% is inappreciable.

16157. **KEITH, HADDOW M. The effect of various factors on experimentally produced convulsions.** *Amer. Jour. Dis. Children* 41(3): 532-543. 1931.—A 1% suspension of thujone is a suitable preparation for experimental production of convulsions. Rapid dehydration reduces the susceptibility of the rabbit to experimental convulsions, at least to some extent. Reduction of the intake of fluid to nothing for a considerable period does not have a similar effect. Acetone, ethyl aceto-acetate and diacetone alcohol reduce the susceptibility of the rabbit to experimental convulsions. Diacetone alcohol has the most pronounced effect. None of these drugs causes dehydration of the brain tissue. The anesthesia induced by diacetone alcohol can be interrupted by the injection of thujone.—*Author's conclusions.*

Path. & Bact.* 33(4): 889-912. 1930.—This agent kills cats and rabbits by blocking the pulmonary circulation and causing vasoconstriction of the coronary arteries.—*A. E. Boycott.*

16159. **KISCH, BRUNO. Differenzierende Wirkungsanalysen von Herzgiften. VI. Die Wirkung von Azetaldehyd auf das Froschherz.** *Arch. Exp. Path. u. Pharmakol.* 138(5/6): 329-338. 7 fig. 1928.—Concentrations of 0.001-1% have the same effect on the heart in situ and the perfused frog heart. Origin of impulses is hindered, the effect being reversible except at high concentration. The conduction of impulses was not disturbed. An effective dose always has a negative inotropic action. Acetaldehyde has the same antagonistic effect to Ca as known for Mg. Atropine does not change the action of acetaldehyde.—*H. Graf.*

16160. **KLIMKO, D. von. Versuche über die Wirkung verschiedener Avertindosen auf den Menschen.** *Schmerz, Narkose-Anaesthesie* 3(3): 89-91. 1930.—The limit for complete amnesia was 0.06 gm. per kgm. body wt. and 0.08 gm. the limit for deep anesthesia.

16161. **KOCHMANN, M. Zur Prüfung und Beurteilung einiger neuer Lokalanästhetika.** *Arch. Exp. Pathol. u. Pharmakol.* 151(1/2): 100-106. 1930.—Cocaine, novocaine, percaine, panthesin and a new cocaine derivative, 1112, were compared as to the minimal quantities required for anesthesia of the cornea of rabbit, and paralysis of sensory and motor nerve of frog. The toxic dose was related to the minimal active concentration. The effect on blood vessels was studied on *Läwen-Trendelenburg* preparations, and the possibility of destruction by the tissues was examined by frog heart perfusions. "1112" was the best of all; percaine also is considered a valuable new local anesthetic. Panthesin has the properties of novocaine.—*H. Graf.*

16162. **KOLLER-AEBY, H., und TH. KOLLER. Zur pathologisch-anatomischen Begründung der Behandlung mit kolloidem Silber.** *Virchow's Arch. Path. Anat. u. Physiol.* 278(1): 84-109. 13 fig. 1930.—The affinity of the reticulo-endothelial cells, especially Kupffer cells, for a colloidal Ag preparation increases with involvement of their function. The deposition of Ag is related to local

acidity, which also explains the therapeutic action of other heavy metals. In like manner the deposition of Ag in the liver and kidney may be explained.—*Author's summary (transl. by J. C. Munch).*

16163. **KOSAKAE, JIRO. Pharmakologische Untersuchungen über die Wirkungen des Plazentarextrakts.** *Kinki Fujinkwa Gakkwai Zasshi (Jour. Kinki Gynecol. Soc.)* 11: 27-37. 1928.—The author's hydrolytic extract of the placenta had, in general, the same effect as placental extract (Ciba) on the uterus in situ as well as on the surviving uterus and intestine in vitro. Respiration was increased by the two extracts. The blood pressure sank in the normal animal, but rose in most pregnant or puerperal cases. The two preparations had an inhibiting action on the perfused frog heart; first an inhibiting, then a stimulating action on the rabbit heart. They produce a contraction or a dilatation of the peripheral, vascular system according to the region involved.

16164. **KRAUSE, F. Ueber den Einfluss des Kohlenmonoxydes auf den peripheren Nerven.** *Acta Psychiatr. et Neurol.* 5(4): 473-491. 3 fig. 1930.—In 18 experiments on frog nerve-muscle preparations, of which illustrative examples only are cited, the effect of CO on the conductivity and excitability of nerve was transient, recovery following as soon after the introduction of air as after N suffocation. This is evidence against the theory of chemical union between CO and nerve substance, since break-up of such a chemical compound takes place only slowly. The direct excitability of the muscle substance itself, however, was greatly diminished by a slight concentration of CO, and the effect was removed only by long exposure to air. Hence Krause deduces a chemical union between muscle substance and CO. He attributes the CO neuritides in part to the mechanical effects of pressure and hemorrhage, and in part to a direct toxic influence.

16165. **KRITSCHEWSKI, I. L. Ueber den Mechanismus der Wirkung von Wismutverbindungen auf Spirochäten.** *Zentralbl. Bakt. I Abt. Orig.* 118(1/2): 16-25. 1930.—The spirochaetes of recurrens, at the height of the infection (in mice) immediately before exitus, are killed by Bi preparations. From this it is concluded that under experimental conditions of research which resemble infectious icterus and also relapsing fever, Bi exerts the same action on *S. obermeieri* as on *S. icterogenes*. The reticulo-endothelial system is considered to have determined the completeness of the therapeutic effect of the Bi preparation in the same manner as is the case with other chemical compounds. The therapeutic action of Bi manifests itself in infectious icterus as also in recurrens in similar form, in principle, and is considered to depend upon the immediate, direct action of the Bi on the spirochaete. This latter is considered to manifest itself, both in the destruction of the micro-organisms and in the decrease of their virulence under the influence of the metal.—*Author's summary (transl. by C. S. Leonard).*

16166. **KYRIELEIS, WERNER. Versuche über Strychninwirkung bei der sog. Pupillotonie. (Zugleich ein Beitrag zur Frage der Strychninwirkung auf die normale und pathologische Pupillenbewegung.)** *Graefe's Arch. Ophthalmol.* 123(1): 1-19. 1929.—Strychnine increased the speed of reaction to light in normal eyes, but did not affect the accommodation mechanism. It does not appear to act on tonus of the iris muscle directly; but appears to act through the oculomotor nucleus. Pilocarpine appears to act directly on pupil tonus. In eyes in which accommodation to light was poor, and at times hardly present, strychnine increased this power.

16167. **LANG, S., u. L. SZENTHE. Über die Verhinderung der Arteriosklerose.** *Arch. Exp. Path. u. Pharmakol.* 151(3/4): 253-256. 1930.—In 3 cases out of 7, insulin, and in 5 cases out of 9, ergotamine prevented the development of arteriosclerosis in rabbits, following daily doses of epinephrine. Four controls.

16168. **LAUNOY, L., P. NICOLLE, et Mlle. M. PRIEUR. De l'action trypanocide synergique du 205 Bayer-309 Fourneau et de quelques composés organiques d'antimoine, sur l'infection expérimentale à Trypanosoma congolense, de la souris et du cobaye.** *Compt. Rend. Soc. Biol.* 106(9): 712-715. 1931.—The para-acetylaminophenyl- stibinate of Na, Sb trithioglycollate of Na and Sb trithioglycollamide were used. A synergistic trypanocidal action between 309 Fourneau and the Sb compounds was demonstrated. Either of the trivalent Sb compounds with 309 Fourneau, injected subcut., produced entire freedom from parasites in 100% of cases in both hosts. Certain proportions were found best. These combinations have no preventive properties against infections in the mouse.—*E. Weiner.*

16169. **Le GOFF, J. M. Action hypotensive du cobalt.** *Compt. Rend. Soc. Biol. Paris* 101: 797-799. 1929.—After intravenous injection of 0.5 gm. Co in a rabbit, a considerable fall of blood pressure was observed. This also occurs in man 3 min. after intramuscular injection of 0.2-0.5 gm. Co.—*K. Pirschle (transl.).*

16170. **LENART, GEORG, und EMIL v. LEDERER. Die Parathormon-Eosinophilie diphtheriekranker Kinder.** *Arch. Kinderheilk.* 93(1): 55-64. 1931.—After an eosinophil count, 1 unit parathormone per kgm. body wt. was given diphtheritic children (no. not stated) on the 7-10th day of the disease; further counts were made at 5 and 24 hrs. thereafter. In normal children the count is reduced 5 hrs. after administration of parathormone, returning to the initial value at 24 hrs.; in diphtheritic children the count was increased at 5 hrs. and normal again at 24 hrs. Apparently the toxic action of diphtheria on the parenchymatous cells of the parathyroid was responsible for this reaction.

16171. **LENART, GEORG, und EMIL v. LEDERER. Die Parathormoneosinophilie gesunder und exsudativer Säuglinge.** *Arch. Kinderheilk.* 93(3): 181-187. 1931.—Eosinophilia before and 6, 12, 24, 48, and 72 hrs. after injection of 10 units parathormone into 9 healthy infants 3-12 mos. old (to establish normal values) and 10 with moderate to severe exudative diathesis showed that in all infants healthy and ill there was a simple curve returning to initial values in 48 hrs. and a delayed curve requiring 72 and more hrs.; each type showed 2 forms. The eosinophilia in infants is more labile than in older children; this lability was increased by exudative diathesis.

16172. **LENZI, LAMBERTO. Il sistema reticoloendoteliale nella difesa organica. [Reticulo-endothelial system and organic defence.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 825-828. 1930.—In animals previously treated with colloidal metals no particular resistance is developed against organic poisons. The R.E.S. is not able to increase resistance to alkaloids (quinine sulphate and morphine chloride).—*M. Comel.*

16173. **LESTSCHINSKAJA, OLGA. Über den Einfluss des Nicotins auf die Körpertemperatur und über den Mechanismus seiner Einwirkung.** *Zeitschr. Ges. Exp. Med.* 69(1/2): 14-28. 1929.—Chronic poisoning was induced in 21 rabbits and 10 guinea-pigs by subcutaneous injection of 0.2% aqueous solution of nicotin, at first 0.001 gm. per kgm. body weight, with a gradual increase if the resistance of the animal permitted; the injections were suspended if spasms or marked loss of weight was observed. Rectal temperature was taken in 17 rabbits and 5 guinea-pigs from the beginning of the introduction of the poison; in the remainder of the animals only after interruption of the poisoning already begun. The temperature was taken before injection, 5, 10, 15 and 30 min. later and at hourly intervals thereafter. The experimental periods for the different animals varied in length from 1 day to 2 yrs. An alteration in body temperature was produced by nicotin, in the great majority of cases a fall in temperature, beginning 2-3 min. after injection and progressing for 2-3 hrs.; thereafter a tendency to rise was observed. It was more marked in guinea-pigs (2°-3.5°) than in rabbits (0.5°-2°). This lowering of temperature might be due either to increased loss of heat through the skin, or to decreased heat-production. Measurements of skin temperature to determine this question, on 8 guinea-pigs and 8 rabbits,

for periods varying from 1-6 days for the rabbits and 4-7 days for the guinea-pigs, gave, in the majority of cases, a fall in temperature, the skin temperature running nearly parallel with the inner temperature, the temperature of the environment remaining normal. The lowering of body temperature, then, cannot be attributed to increased loss of heat, but must be due to a change in heat production. The hypothesis that this might be due to the effect of nicotin on the autonomic nervous system was next tested. A series of 18 experiments showed that the supine position in itself caused a fall of 2°-2.5°; therefore the experiments on the nerves were so conducted as to leave the animal freedom of movement. The sympathetic nerves were cut in 7 rabbits with resultant rise of temperature from 1° to 0.6°. In 6 rabbits the vagi were cut; the temperature fell in 4 cases 0.1°, 0.2°, 0.3°, and 0°, respectively; in the other 3 cases, the sympathetic had been cut before the vagi; the temperature fell when the 2d operation was performed the day after the first and rose when the operation was done a month afterward. After determination of the effect of section of these nerves in itself on heat-formation, nicotin was given after section of the sympathetic in 3 experiments; the effect of nicotin was noticeably weakened. In 4 experiments the vagi were cut, and nicotin then exercised no effect at all on the body temperature.

16174. [LEVINA, TS. A.] ЛЕВИНА, Ц. А. Об эритропоэтической функции белых крыс при парентеральном введении казеозана. [Erythropoietic function of white rats with parenteral administration of caseosan.] [German summary.] Одесский Медицинский Журнал (*Odessaer Med. Zeitschr.*) 4(5/7): 367-370. 1929.—Repeated parenteral administration of caseosan in doses of 0.5 cc. to 13 rats, showed that their wt. does not change; the number of erythrocytes in the majority of cases was considerably increased. Hemoglobin fluctuated, with a tendency to increase; the color index predominantly decreased; the number of erythrocytes with reticulo-filamentous substance increased; the number of such erythrocytes in 1 cu. mm. increased. Repeated doses of over 0.5 cc. resulted in loss of weight, decrease of the erythrocytic count and decrease of Hb. The color index usually remained the same. This influence of caseosan continues for at least 3½ wks.—*B. Van Rosen.*

16175. **LEYS, DUNCAN.** The influence of adrenaline on carbohydrate metabolism. *Jour. Physiol.* 71(3): 275-279. 1931.—The av. of 9 estimations of blood lactic acid of resting adult convalescent patients was 15.8 mgm. %. Injection of 0.5 or 0.75 mgm. adrenaline caused increase in lactic acid of from 28-224%. Increases in blood sugar showed no simple relationship to increases in lactic acid, and changes in blood-pressure bore no simple relationship to changes in blood sugar or lactic acid. The diastatic activity of the blood in 2 cases was not increased by adrenaline. By the method of yeast fermentation, the blood was shown to have a "residual reduction" corresponding to about 20 mgm. glucose per 100 cc. This figure showed no appreciable alteration with adrenaline.—*Author's summary.*

16176. **LINDNER, F., und R. RIGLER.** Über die Beeinflussung der Weite der Herzkranzgefässe durch Produkte des Zellkernstoffwechsels. *Pflüger's Arch. Ges. Physiol.* 226(6): 697-708. 6 fig. 1931.—Exp. were conducted on the effects of chemicals on the revival of a hypo-dynamic heart, and on the production of coronary dilatation. Extracts from heart muscle are effective but do not in any way indicate a specific hormone, since similar effects are obtained from extracts of skeletal muscle, pancreas, liver and kidneys. The work was undertaken to analyze the beneficial effect of tissue extracts in angina pectoris and one such extract (lacarnol) had a very high capacity of inducing coronary dilatation in perfused rabbit hearts. Effects on the contraction of frog heart were obtained with hexosediphosphoric acid and with inert colloidal suspensions of Al silicate but these were not effective clinically. Effective extracts give reactions for pentose and purine. Adenosin appears to be an effective agent in such reactions. The blood of arteriosclerotic patients has been found to have a low content of adeninenucleotides.—*H. C. Bazett.*

16177. **LIPMANN, F.** Über den Tätigkeitsstoffwechsel des fluoridvergifteten Muskels. *Biochem. Zeitschr.* 227 (1/3): 110-115. 1930.—The muscles of a frog poisoned with fluoride can perform work without raising their lactic acid content. In these muscles there is a more rapid decomposition of phosphagen, an esterification of hexose with phosphate and a splitting of adenyl-pyrophosphoric acid. After several contractions the poisoned muscles become rigid. This behavior is similar to that of muscles poisoned with mono-iodoacetic acid.—*Author's summary (transl. by A. G. Mulder).*

16178. **LO CASCIO, GERLANDO.** Rapporti tra azione sul tessuto emopoietico e fissazione nell'apparato reticolo-endoteliale del solfuro di rame colloidale. [Relation of the action of colloidal copper sulphide on the hemopoietic tissue and its retention by the reticulo-endothelial apparatus.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 819-822. 1930.—R.E.S. of bone marrow, spleen, and liver was blocked by intravenous administration of colloidal Hg sulphide, followed by Cu sulphide administration. The erythroblastic reaction (entrance into blood of nucleated erythroblasts) was suspended. It was re-established if smaller doses of the blocking substance were injected.—*M. Comel.*

16179. **LO FASO, GIOV. BATT.** Sulla ricerca di tracce minime di mercurio nelle orine e nei liquidi organici. [Minimal traces of mercury in urines and organic fluids.] *La Med. del Lavoro* 12: (1-6). 1928.—Methods of high sensitivity recorded in this work are more suitable for study of traces of Hg in mixtures or in inorganic combinations; but for clinical studies, they have been less satisfactory since traces of organic substances in the fluids studied can obscure and sometimes cause reactions (reduction of $AuCl_3$). The application of spectroscopic analysis, as given in early references was not tried as a clinical method but an attempt has been made to coordinate the advantages of several methods in order to develop a clinical technic sensitive, objective in the presence of foreign substances, safe and rapid.—*Author's summary (transl. by J. G. Edwards).*

16180. **LUDWIG, HERBERT.** Experimentelles zur Komplexbildungstherapie der chronischen Blei- und Quecksilbervergiftung. *Biochem. Zeitschr.* 210(4/6): 352-392. 1929.—The combination of Hg and protein is broken up by KI forming a soluble K-Hg-iodide complex. Treatment of chronic Hg poisoning with KI may result in flooding the system with Hg. A more rational treatment would promote the formation of non-toxic insoluble HgS through use of strontium sulpho-acetate. Pb compounds in the circulating blood are only very slightly activated by KI treatment. This may hasten Pb excretion, but many investigators report acute Pb poisoning symptoms after KI therapy. The danger is greater in Hg poisoning. Test tube reactions between K, Hg and various anions in the absence and presence of serum were studied. These explain the danger of KI therapy in terms of solubilities of complex Pb and Hg ions.—*W. N. Berg.*

16181. **LUISADA, A.** Über die Bedeutung der Ringerlösung für Gefässweite und -Durchgänglichkeit für Zucker. *Arch. Exp. Path. u. Pharmakol.* 122: 228-237. 1927.—Addition of 0.01% each of KCl and $CaCl_2$ to a sol. of NaCl containing glucose for perfusing the hind extremities of frogs does not change the size of vessels but increases the discharge of glucose into the tissues. Addition 0.01 or 0.1% $NaHCO_3$, with or without CO_2, to the sol. of NaCl or to Ringer sol. dilates vessels and raises glucose discharge, although NaOH or phosphate mixture, equal in pH to the bicarbonate solution, contracts vessels and does not alter discharge of glucose. Addition of veronal, CO_2 or acetic acid in dilating concentration does not increase discharge of glucose. From these results, it is probable that $NaHCO_3$ has a specific action on penetrability, not dependent on alkalinity, and an

entirely independent action on the size of blood vessels.—*Author's summary (transl. by E. V. Lynn).*

16182. **LUMIÈRE, AUGUSTE, et R.-H. GRANGE. Relation entre la toxicité, le pouvoir hémolytique et la tension superficielle de quelques substances hémolysantes chimiquement définies.** *Compt. Rend. Soc. Biol.* 100 (14): 1210-1211. 1929.—Saponin, lecithin, hexylresorcinol, "Nekal" and "Brecolane" (Na salts of sulphonic derivatives of naphthol homologues) were compared. No relationship was found between surface tension and hemolytic power, and that between toxicity and hemolytic power was not a proportional one.

16183. **LÜTOLF, WERNER. Untersuchungen über die Sensibilisierung von Adrenalin durch Thyroxin am überlebenden Säugetierherzen.** *Zeitschr. Biol.* 90 (4): 334-346. 10 fig. 1930.—Very dilute sols. of thyroxin (1: 400,000, 1: 600,000, 1: 800,000) have neither an augmenting nor an inhibitory effect on strength and frequency of the beats of a surviving rabbit's heart, while concentrations of 1: 20000 are depressing. Perfusing the surviving heart with a sol. containing thyroxin and epinephrine increases in a certain number of cases the action of epinephrine alone about 7% as to frequency and 28% as to height of contraction. The treatment of rabbits for some days with thyroxin produced in the surviving heart an enormous sensitization to the action of epinephrine. While on the average the hearts of normal rabbits react towards epinephrine in a conc. of 1: 5 million, the hearts of animals treated with thyroxin react to epinephrine sols. of 1: 3,200 million.—*L. Asher.*

16184. **LUTOWSKI. Die Bindung von Thymol durch die Stroma-Substanz der roten Blutkörperchen. (Ein Beitrag zur Theorie der Narkose.) [Thymol bound by the stroma of red blood cells. (A contribution to the theory of anesthesia.)]** *Schmerz, Narkose-Anaesthesie* 3 (7): 233-247. 1930.

16185. **MACCO, G. Di. Influenza del vago sulla azione ipotensiva del magnesio. [Influence of vagus on the hypotensive action of Mg.]** *Riv. Patol. Sperim.* 5 (2/3): 223-232. 2 fig. 1930.—After cutting the vagus the hypotensive action of Mg is greatly reduced. Vagotomy following administration of Mg does not produce hypertension. It is therefore assumed that the diminution of pressure caused by Mg is due at least partly to a prevailing vagal tonus affecting the heart's activity.—*M. Comel.*

16186. **MACCO, G. Di. Influenza dell'atropina sull' azione ipotensiva del magnesio. [Influence of atropin on hypotensive action of Mg.]** *Riv. Patol. Sperim.* 5 (4/5): 393-402. 2 fig. 1930.—In dogs treated with atropine the hypotensive action of Mg is less intense and lasting, but more rapid. If the animal is previously treated with Mg, atropine produces an additional diminution of pressure.—*M. Comel.*

16187. **MacKAY, MARGARET E. Histamine and adrenaline in relation to the salivary secretion.** *Jour. Pharmacol. & Exp. Therap.* 37 (3): 349-358. 1929.—In certain experiments on cats in which injection of histamine produced only a slight secretion of saliva the fall in blood pressure was followed by a rise above normal. After extirpation of both adrenals in cats and dogs the injection of histamine produced merely a fall in blood pressure and an augmented secretion of submaxillary saliva which was more marked after previous stimulation of the chorda. If adrenaline was slowly injected into the adrenalectomized animal the augmented histamine secretion was greatly diminished. It is suggested that adrenaline is antagonistic to the histamine action on the submaxillary gland.—*O. O. Stoland.*

16188. **MAGNUS, RUDOLPH. Lane Lectures on experimental pharmacology and medicine.** *Stanford University Publ. Med. Sci. Ser.* 2 (3): 241-342. Portrait. 1 fig. 1929. Price $1.50.—Three of the five lectures to have been given by Magnus in 1927 had been completed before the author's death. These have been edited by his friend H. H. DALE, and are given together with a short biography, also by Dale. A complete list of the publications of Magnus and his collaborators, both at Heidelberg and at Utrecht is included. The 1st lecture, on the experimental pathology of the lungs, details the results obtained by several observers, in his laboratory, on the pathology of the isolated lung, using the methods hitherto applied to the study of the physiology of isolated organs. The 2nd lecture, on the importance of choline as an intestinal hormone, gives in some detail the experimental background for the beliefs of the Utrecht school in this important field. The 3rd lecture, on "The Physiological A Priori," is a brief discussion of the important rôle played by physiological apparatus in psychic function. "We possess numerous mechanisms acting unconsciously and partly subcortically which prepare the work beforehand for our psyche, and the results of which are a priori present before sensory observation and its psychological appreciation start."—*E. E. Nelson.*

16189. **MALANDRUCCO, ILARIA. Contributo alla teoria della narcosi. Il coefficiente di ripartizione tra acqua e lipidi a vario contenuto di doppi legami. [Studies on the theory of narcosis. The coefficient of distribution between water and lipids with various degrees of unsaturation.]** *Biochim. e Terapia Sperim.* 17 (7): 287-294. 1930.—With bromural (α-bromisovalerylurea, a hypnotic of the ureide series), no relation exists between its solubility in fats and the number of double bonds. The assertion of Velluz, that the distribution coefficient (oil: water), of the hypnotic compounds derived from malonyl-urea, varies directly with the number of double bonds, is not supported.—*M. Comel.*

16190. **MANCKE, RUDOLF. Untersuchungen über die Wirkung des Calciumchlorids auf das Warmblüterherz.** *Arch. Exp. Path. u. Pharmakol.* 149 (1/2): 67-75. 2 fig. 1930.—Using the isolated cat heart perfused with increasing concentrations of $CaCl_2$, the action of the Ca from minimal to maximal poisoning has been studied. Doubling the $CaCl_2$ content of the Locke solution increases the outflow more than can be explained by the slight change in height of contraction. At this concentration there is an increase in coronary outflow, explained by a dilatation of the vessels. This effect continues longer than that on the muscle which is slight at this concentration.—*From author's summary (transl.).*

16191. **MANWELL, REGINALD D. Further studies on the effect of quinine and plasmochin on the avian malarias.** *Amer. Jour. Trop. Med.* 10 (6): 379-405. 1930.—250 birds were used, and 5 strains of bird malaria: *Plasmodium elongatum* (Huff), *Plasmodium cathemerium* (Hartman), a strain of *Plasmodium praecox* (Grassi and Feletti) from Virginia, one from Germany and one from New York. All three of the latter reacted in essentially the same manner to treatment, but important differences were demonstrated between the three species. It appears to be possible to sterilize all cases of *Plasmodium elongatum* with plasmochin, and some of *Plasmodium praecox*, but *Plasmodium cathemerium* infections have so far proved completely refractory to this drug as far as sterilization is concerned. Quinine treatment was relatively ineffective with all three species, and almost entirely so with regard to sterilization. It had the least effect on *Plasmodium elongatum*. A number of cases of *Plasmodium praecox* were treated with each of these drugs for eight weeks, the treatment being started during the acute stage. Except for one case of the 10 receiving plasmochin, sterilization was not achieved in any of the birds in the 2 series. It was shown however, that the parasite level during treatment was considerably lower in the plasmochin-treated cases than in those receiving quinine. In no case did sterilization occur in a bird not receiving treatment. A further result of the experiments was the demonstration that treatment is most effective when started just after inoculation with parasites. It was also shown that chronic infections of *Plasmodium praecox* differ very much in the individual parasite levels established and that previous treatment has little effect on them. Female canaries were used throughout the study.—*R. D. Manwell.*

16192. **MARCO, R. de. Azione di alcune sostanze**

chimiche sull-attività motoria dell'intestina. [Action of some chemicals on the motor function of intestine.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1006-1008. 1930.—Administration of adrenaline or atropine to dogs in which an intestinal Vella's pouch had been made was followed by a diminution of intestinal motility. Pilocarpine showed no noticeable action. Nicotine caused a marked increase of motility.—*M. Comel.*

16193. MARKOWITZ, J., and FRANK C. MANN. The rôle of the liver and other abdominal viscera in the destruction of epinephrin in the body. *Amer. Jour. Physiol.* 89(1): 176-181. 7 fig. 1929.—Pressor effects of intraven. epinephrine were studied in normal, dehepatized and eviscerated dogs. No evidence was found to support the belief that destruction is the special function of the liver or other abdominal viscera. This destruction apparently occurs throughout the body.—*I. I. Lemann.*

16194. MARKOWITZ, J., [et al.]. The physiologic action of rattlesnake venom (crotalin). IX. J. MARKOWITZ, HIRAM E. ESSEX, and FRANK C. MANN. Activity of protein fractions of crotalin. X. EDWARD J. BALDES, HIRAM E. ESSEX, and J. MARKOWITZ. Influence of crotalin on the viscosity of blood. *Amer. Jour. Physiol.* 97(1): 22-25; 26-31. 1931.—IX. The characteristic activity of rattlesnake venom was found present in the purified albumin fraction of the venom. The globulin fraction was inert as was the protein-free fraction. All efforts to separate the venom into several toxic components were unsuccessful. Thus far it has not been shown that the toxic manifestations of crotalin are due to a number of substances.—X. Dried venom of *Crotalus atrox* (crotalin) added to the blood of the dog in vivo or in vitro caused a marked increase in viscosity due to the increase in volume of the erythrocytes, as the addition of crotalin to the plasma alone did not appreciably change its viscosity.—*Authors' summaries.*

16195. MARKOWITZ, CECILE. Response of explanted embryonic cardiac tissue to epinephrine and acetylcholine. *Amer. Jour. Physiol.* 97(2): 271-275. 1931.—A study was made of the influence of epinephrine and acetylcholine on the heart rate of chick embryos. The hearts were either excised and studied in Locke's solution or explanted according to the methods of Carrel and Maximow. In general epinephrine and acetylcholine exerted their typical effect on embryos 6 days old or older. Many of the 5-day-old embryos showed hearts refractory to epinephrine and acetylcholine and the action of these drugs became markedly less apparent as the age of the embryo decreased. In the case of 72-hr. embryos less than ¼ of the fragments responded. Because of the lack of definite knowledge, both in regard to the exact site of action of these drugs, and to the time of development and beginning function of the intrinsic nerve mechanism of the heart, it would seem that these results can best be explained on the basis of some intermediary substance being necessary for the action of the drugs. In explants from embryonic hearts it often happened that a fresh explant from a 2-day-old heart would be negative to epinephrine or acetylcholine whereas on cultivation for 24 hrs. these drugs would exert their typical results.—*Author's summary.*

16196. MARTINI, EMILIO. Condizionali biochimiche della narcosi da magnesio. [Biochemical conditions of Mg narcosis.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 946-948. 1930.—After Mg narcosis the animals showed increased blood Mg and a decreased Ca content while the alkali reserve values of blood were higher. Blood K was in half the cases higher than that prior to narcosis.—*M. Comel.*

16197. MARULLAZ. Action des sels de magnésium sur la genèse des tumeurs du goudron. *Rev. Internat. Méd. et Chir.* 41(2): 20-24. 1930.—To each of 8 rabbits 10 mgm. of $MgCl_2$ was administered daily for more than 5 mos.; after about 1 wk. of the Mg treatment, weekly painting with tar of 1 ear of each of these 8 together with 10 untreated controls, was begun. At the end of the treatment 3 of the 8 Mg-treated animals showed only a slight follicular hypertrophy of the treated regions; 5 showed a slight abnormal activity of the epithelium and in 1 case a benign papilloma, in another a small bleeding tumor which became detached spontaneously. In 3 rabbits treated for 6 mos. with tar and bearing developed tumors, administration of Mg salts did not cure but seemed to check the development of the growth.

16198. MASCHERPA, P., e G. BELLUZZI. Emanazione di radio e azione fisiologica di alcuni farmaci. [Ra emanation and physiological action of some drugs.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 944-946. 1930.—In animals treated with Ra emanation the poisoning following strychnine and morphine was more quickly manifest and more severe than in the absence of Ra emanation.—*M. Comel.*

16199. MAYNE, BRUCE. Tests on the effects of coumarin on the life of the mosquito and the malaria parasite. *Indian Jour. Med. Res.* 17(3): 963-969. 1930.—Coumarin, 1—1,000-2,000 solutions, killed Anopheles and Culex mosquitoes, probably not through imbibing the liquid, but as the result of asphyxia and paralysis. This viewpoint is taken for the following reasons: Several trials were made with newly emerged or unfed wild mosquitoes on the one hand, and mosquitoes whose abdomens prior to the test appeared to be distended with liquid, on the other. In both instances the mosquitoes succumbed in a similar manner to the action of the chemical. Several instances were observed in which mosquitoes exposed to the fumes of the chemical were evidently overcome within 4 hrs., but when removed to clean untreated cages revived on the following morning. No actual proof could be had, in the majority of experiments, of the mosquitoes having imbibed the strong solutions before being affected through their respiratory channels. In a few cases thirsty mosquitoes having engorged themselves with the strong solutions, when removed to fresh untreated cages apparently remained unaffected. The lethal action of coumarin solutions by actual contact of sporozoites with the liquid may probably be regarded as of only academic interest. This would have at most a transient limited application to any economic measure. The results of the tests could reasonably be interpreted to indicate that coumarin taken with the liquid extracted from a clover blossom would have no deterrent action on oöcysts and sporozoites undergoing development in the infected mosquito. The only effect conceivable would be the destruction of the sporozoites deposited in the coumarin substance at the time of visiting a leguminous plant. This might have an economic bearing only as regards an augmented discharge of sporozoites from the salivary glands at the time the mosquito might partake of vegetable food.

16200. MELVILLE, K. I., and M. BRUGER. Concerning the alleged antidotal action of sodium thiosulfate in mercuric chloride poisoning. *Jour. Pharmacol. and Exp. Therapeut.* 37(1): 1-8. 1929.—The life of dogs receiving a fatal dose of $HgCl_2$ cannot be prolonged by the subsequent injection of $Na_2S_2O_3$. The diuresis produced by $HgCl_2$ alone is not affected by the simultaneous injection of $Na_2S_2O_3$, thus indicating that the action of Hg in the body is not affected by the thiosulfate. In other words, there is no evidence that Hg is converted to an insoluble and inactive sulfide.—*W. N. Berg.*

16201. MENDENHALL, WALTER L. Tobacco. 69p. (Harvard Health Talks 17.) Harvard University Press: Cambridge, 1930. Pr. $1.—This is one of a series of public lectures intending "to provide in easily accessible form modern and authoritative information on medical subjects of general importance." Smokers and non-smokers disagree as to the reasons for and value or harm of this habit. These differences have led to rather strong prejudices, but there is little knowledge based on facts. Over-indulgence in tobacco may result in effects on the circulatory system, alimentary tract, respiratory tract, the eyes, and the nervous system. If the indulgence is discontinued the symptoms disappear. The sedative effect on the nervous system has been especially studied by the author who cites the results of his work

published elsewhere. The lack of adequate data on the effect of smoking on growth, on scholarship, on intelligence, and on efficiency, is emphasized. There is no evidence, in spite of published statements to the contrary, that smoking in woman has any effect either on her sexual functions or on her children. The substance responsible for the use of tobacco is nicotine, even in the de-nicotinized brands. The book closes with some quotations regarding smoking by extremists on both sides, and the statement that it will probably be many yrs. before enough accurate observations are made in regard to the effects of its use in moderation.—*E. E. Nelson.*

[Relation between blood glucose and P as influenced by uranyl salts and thymus extracts.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 982-984. 1930.—Injections of uranyl acetate are followed by a diminution of blood P, accompanied in a 1st stage by increase of glucose without glycosuria, whereas in a 2nd stage glycosuria occurred. Thymus extracts lowered blood P and increased blood glucose.—*M. Comel.*

16205. **MICHELAZZI, LUIGI. Sopra l'azione tossica e calcificante dell'ergosterina irradiata. [Toxic and calcifying action of irradiated ergosterol.]** *Riv. Patol. Sperim.* 5(6): 505-521. 1930.—Intravenous administration of irradiated ergosterol was not followed by the toxic symptoms following subcutaneous injections in rabbits. A marked anemia occurred in animals treated subcutaneously. Overdosage leads to Ca precipitation in kidney, aorta, liver, lungs and other viscera in mice, guinea pigs and rabbits.—*M. Comel.*

16206. **MORACCI, E. Sull'azione di varie sostanze chimiche applicate direttamente sui centri corticali sensitivo-motori del cane. [Action of chemicals directly applied on the cortical sensitive-motor centers in dogs.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1003-1006. 1930.—The chloride, nitrate, sulphate, sulphocyanide, of NH_4, K, Na and Li were tested as to their influence on the cortical centers. Only the Li salts exerted a marked stimulation on the centers, followed by clonic and tetanic contraction of the related muscular groups. An action similar to that exerted by Li salts followed creatine application to the cortical centers.—*M. Comel.*

16207. **MÜLLER, HELMUT, und HELMUTH REINWEIN. Zur Pharmakologie des Galegins.** *Arch. Exp. Path. u. Pharmakol.* 125(3/4): 212-228. 1927.—Injection of 2-6 mgm. per kgm. galegine-SO_4 had no effect on 2 fasting rabbits; injection of 12-30 mgm. per kgm. produced a rise in blood sugar; within 15 min. after doses of 30-100 mgm. per kgm. hyperglycemia became very pronounced (lasting several hrs.). The lethal dose was about 120 mgm.; an individual sensitivity also appeared. Dogs given 25-45 mgm. per kgm. galegine-SO_4 died in ½ hr., with hyperglycemia. With smaller doses the animals remained healthy; at 4 mgm. per kgm. a distinct decrease in blood sugar occurred. Hypoglycemic convulsions could not be produced. In pancreatectomized dogs galegine caused a reduction in blood and urinary sugar. In a healthy person and a diabetic 2 mgm. per kgm. caused a drop in blood sugar. Investigations with the enucleated frog eye, on vascular preparations of the frog, on the isolated intestine of the cat, and exps. with blood pressure indicate that the hypoglycemic action of galegine is due to stimulation of the sympathetic nervous system. Its action in producing hyperglycemia, vascular contraction, increase in blood pressure, the reaction of the eyeball, and paralysis of the intestine corresponded to that of epinephrine. Hyperglycemia caused by galegine can be prevented by ergotamine. Hypoglycemic convulsions occurred in rabbits and dogs after administration of galegine and ergotamine. Possibly stimulation of the pancreatic secretion by way of the parasympathetic nervous system causes the decrease in blood sugar after administration of galegine and synthalin.

C. Faust.*

16210. **NISISITA, MASAMI. Studien über das atemerregende Mittel Lobelin. I. Mitt. Beurteilung verschiedener Lobelinpräparate und Vergleich mit Lobelanin und den Gesamtalkaloiden der Lobelia inflata.** [Japanese.] *Okayama Igaku Kwai Zasshi* 39: 1971-1986. 1927.—In order to investigate the stability of lobeline, in relation to its effects a series of experiments was undertaken in which the following were used, a pure crystallized lobeline hydrochloride, prepared by Takeda & Co.; "Lobelin-Ingelheim," in solution in ampoules; and "Lobelinum sulfuricum Merck," in the form of brownish crystals. The action of lobelanine and the total alkaloids of *Lobelia inflata,* both in beautiful white hydrochloride crystals, prepared by Takeda & Co., was also investigated. Freshly prepared solution of lobeline hydrochloride is a stronger respiratory stimulant for the rabbit than "Lobelin-Ingelheim" and "Lobelinum sulfuricum Merck." The emetic action of crystallized lobeline hydrochloride was very weak, the action taking place only with large doses, as much as 4 mgm. per kgm. weight of animal. As the solution became older, the action increased in strength. "Lobelin-Ingelheim" showed a stronger emetic action (at 2 mgm.), and especially in old preparations (at 0.5 mgm.). The emetic action of "Lobelinum sulfuricum Merck" was strongest (at 0.1 mgm.) and was accompanied with diarrhea. Furthermore, lobelanine and the total alkaloids show no strong emetic action (active with 5 mgm.). With *Rana temporaria* crystallized lobeline hydrochloride, and "Lobelin-Ingelheim," were equally active, only the latter responded somewhat less promptly. Lobelanine and the total alkaloids are about ⅓ as active as crystallized lobeline. If one compares the phases of poisoning and the toxicity on the mouse, one notes also that crystallized lobeline is stronger than "Lobelin-Ingelheim." Lobelanine in smaller doses, it is true, evokes more violent cramps; with larger doses the cramps are not so severe, although they last longer than with lobeline. Its lethal dose also is somewhat larger than that of the latter. Besides, it was noted that the manifestations of poisoning, as well as lethal doses of the lobeline preparations are very dependent upon the concentration of the solutions.—From these results it follows, that lobeline, as also lobelanine and the total alkaloids of *Lobelia inflata,* have a very weak emetic action so far as they are pure and their solutions are fresh, that preparation solutions like "Lobelin-Ingelheim," with the decrease in other

activity, possess an increased emetic action, and this change always increases with time, and finally the brownish colored crystals of lobeline have the strongest secondary effect. The secondary effect, especially the emetic action, depends very probably, not upon the accessory alkaloids, but upon changes in lobeline itself.—*Author (courtesy Japanese Jour. Med. Sci. IV.)*. (*Transl. by C. C. Plitt*).

16211. **NISISITA, MASAMI. Über den Einfluss verschiedener Gifte auf das in verschlossenem Raum befindliche Tier.** *Okayama Igaku Kwai Zasshi (Jour. Okayama Med. Soc.)* 40: 533-545. 1928.—Mice in airtight flasks with uniform internal pressure showed decreased length of life when the accumulated CO_2 was removed with KOH; CO_2 can, thus, lead to economy in O consumption in the body. Small doses of morphine decreased the O consumption and increased the resistance to O deficiency; the life of the animal was lengthened and it lived until the O content of the air was below normal. Somewhat larger doses decreased the resistance to O deficiency; yet the duration of life was somewhat increased by the economy of O consumption. The accumulation of CO_2 also acted favorably. In its absence the effect of the morphine was decreased and when the dose was increased the deficiency of O could not be withstood. It is probable that, aside from the CO_2 action mentioned, its stimulating action on the respiratory center antagonized the paralyzing action of morphine. Hexeton caused an increase in O consumption, although it increased the resistance to O deficiency. Life was thus shortened still more when the CO_2 was removed. A narcotic dose of alcohol caused a reduced O consumption and thus lengthened the animal's life. In small doses stimulation occurred and the reverse was true. Narcotic doses of paraldehyde had a similar action, but in suitable doses the effect was more pronounced than with alcohol.

16212. **NITTA, Y. Über die Wirkung einiger ätherischer Öle auf Gonokokken im Reagensglase und im Peritoneum der weissen Maus.** *Dermatol. Zeitschr.* 59 (1): 12-16. 1930.—Of a number of ethereal oils, some were very effective towards gonococci in vitro. For instance guaiac wood oil and oil of bitter almonds inhibited completely the growth of the gonococci at a dilution of 1/6000 to 1/12000. Marjoram oil and lemon grass oil inhibit at 1/12000. Ceylon cinnamon oil at 1/12000-1/16000, Cassia oil at 1/24000 and finally mustard oil at 1/6000-1/48000. In the peritoneum of the white mouse ethereal oils are not effective towards gonococci.—*Author's summary (transl. by F. R. Greenbaum)*.

16213. **NORGAARD, A., and TH. E. HESS THAYSEN. Clinical investigations into the effect of intravenous injection of insulin. I. The blood sugar curve in normal individuals.** *Acta Med. Scandinavica* 72(5/6): 492-510. 1929.—Intraven. injection of 12 international units of insulin into 9 men and 9 women with normal carbohydrate metabolism produces a blood sugar curve that shows a typical course with the technique employed. The curve shows first an abrupt and fairly straight fall to the lowest blood sugar value most often found in the blood sample taken 25 min. after injection. The lowest blood sugar value found was 20 mgm. %. The fall of the curve is called the *"assimilation line."* The fall is followed by a rise, during which the blood sugar concentration is restored to or nearly to its initial value. The rise—called the *"restoration line"*—consists of two components, a steeper rise, the *"primary"* rise, which lasts 10-20 min., rarely more, and a more slowly progressing rise, called the *"secondary"* rise, in the following 55-110 min. In men the "restoration line" runs a steeper course, and the distinction between the "primary" and the "secondary" rise is more pronounced than in women. In the same individual, 2 curves, taken at different times, show a striking uniformity, suggestive of a certain constitutional moment influencing their course. In the assimilation line there is much variation in the relation between the sugar content of the *venous and the capillary blood;* not until 80 min. after the injection, i.e., 50-60 min. after the end of the fall, is there constantly a greater glucose concentration in the capillary blood than in the venous blood, with a difference in one exp. of 25 mgm. %. The assimilation line is an expression for the amount of blood sugar assimilated in the organism under the influence of insulin. The *"assimilation index"* designates the amount of blood sugar assimilated per min. in percentage of the initial blood sugar value. The assimilation index varied in different individuals from 1.7 to 3.3; in the same individual it varied from 2.9 to 3.3.—*Authors' summary.*

16214. **OCHIAI, KUNITARO. On the histological studies of the mechanism of insulin and synthalin action.** *Nagoya Jour. Med. Sci.* 5(2): 110-124. 1931.—(I) In the muscles of normally fed rats treated with insulin an increased deposit of glycogen was observed, especially during convulsions, while the glycogen in the liver progressively diminished. In rats starved for 24 hrs. both liver and skeletal muscle were deprived of glycogen, and administration of insulin induced no glycogen production. It is suggested that a part of the sugar that disappears from the circulating blood during the action of insulin may be stored as glycogen in skeletal muscle.—(II.) Glucose sol. was given subcut. to starved rats and intraven. to starved guinea pigs and rabbits; glycogen was found stored soon afterward, most of it in the liver, less in the muscles. When insulin was given with the glucose, little or no glycogen was found in the liver of rats and guinea pigs, but much in the muscles; but in rabbits a large deposit of glycogen was found in the liver and none in the muscles.—(III.) No unmistakable difference was observed between the lipid bodies of insulin-treated rats and those of controls. (IV.) Preparations in alcohol, stained with hematoxylin and eosin, of liver, kidney, suprarenals and skeletal and heart muscle revealed no marked histologic changes due to insulin. (V.) A group of normal and starved rats was given synthaline subcut. in various doses. In the normal rat, the liver glycogen diminished gradually and usually finally disappeared; muscle glycogen did not entirely disappear, though the amt. present was small. The simultaneous administration of synthaline and glucose solution to normal and starved rats caused a deposit of glycogen parallel to that induced by similar injections of insulin and glucose.—(VI.) Injection of synthaline into rats was followed by a slight increase of fat in the muscles; large doses caused a marked increase in fat in the parenchyma cells of the livers and kidneys. (VII.) Livers and kidneys of rats poisoned by synthaline showed fatty infiltration, dilatation of blood vessels, degeneration of protoplasm, and in severe cases necrosis (of parenchymal cells of the liver, epithelial cells of the kidney).

16215. **OCHSNER, ALTON, I. M. GAGE, and R. A. CUTTING. The value of drugs in the relief of ileus: an experimental study.** *Arch. Surg.* 21(6 [part I]): 924-959. 17 fig. 1930.—The authors criticize previous experiments as made on animals presenting intestinal reactions fundamentally different from those in man, particularly cats (unduly resistant to intestinal obstruction) and rabbits (intestinally hyperactive). Ochsner and his co-workers used dogs exclusively, which they consider more like men in intestinal reactions than most other animals. Experiments were made on 63 dogs (some normal, others previously subjected to experimental obstruction) with pituitary extract, physostigmine, peristaltin, pitocin, choline, acetyl choline and hypertonic NaCl solution. Physostigmine was the only substance found consistently effective in raising intestinal tone and motility. The authors believe that its effect is enhanced in early intestinal obstruction, and suggest that the obstructed intestine may be hyperexcitable. The other substances used in these experiments, which had either a depressant or an inconstant and insignificant effect would therefore appear to be of slight or no value.

Med. Brno)* 6(57): 1-21. 2 pl. 1928.—The amount of epinephrine in a novocaine, tutocaine or psicaine sol. was determined by a method similar to that of Oliver-Schafer. The sol. to be tested was perfused through the aorta into the frog, and the number of drops passing through the preparation was counted. The "Index" is the ratio of drops of Ringer solution to drops of solution to be assayed. For example: tutocaine 1:2000 = 0.6, epinephrine 1:800,000 = 2.0. The "index" of both should be $(0.6+2.0)/2=1.3$. The "index" actually found after perfusion of a mixture of the two sols. was 1.53. The method was used in the determination of the amount of epinephrine necessary to neutralize the vasodilator properties of an anesthetic.—*French summary (transl. by G. T. Cori).*

16222. **PETROFF, J. R. Untersuchungen über das Verhalten des Blutdrucks und der Herztätigkeit bei Bleivergiftung.** *Arch. Exp. Pathol. u. Pharmakol.* 148 (5/6): 330-341. 2 fig. 1930.—Inhalation of lead sprays produced symptoms of lead poisoning. In the early period of poisoning there was hypertonia, tachycardia, and hypercholesterolemia, that apparently arose from increased tonus of the sympathetic nervous system. Somewhat later hypertonia developed. In a third stage in some animals a hypotonia again developed.

16223. **PLATT, ROBERT. An inquiry into the fate of thyroxin in the treatment of nephrosis.** *Quart. Jour. Med.* 23(89): 129-133. 1 pl. 1930.—Thyroxin administered to nephrotic patients was not all excreted unchanged. Tadpoles fed urine from nephrotic patients to whom thyroxin had been administered metamorphosed more rapidly than tadpoles fed urine from nephrotic patients to whom no thyroxin had been administered, but less rapidly than tadpoles to whom urine from normal patients had been administered. Tolerance to thyroxin in nephrosis, therefore, does not depend on its rapid excretion: a considerable part of it is destroyed by the body.

16224. **POLLAK, LEO. Über das Verhalten körperfremder Zuckerarten unter Insulinwirkung. II. Über die Resorption intraperitoneal injizierter Zuckerarten unter dem Einfluss von Insulin.** *Arch. Exp. Path. u. Pharmakol.* 125(1/2): 102-128. 1927.—When sugar-free Ringer's sol. was introduced intraperitoneally in rabbits, first without, then with insulin, sugar passed into the solution from the blood, the concentrations being equalized in 90-120 min.; the final concentration was slightly higher in the Ringer's sol. (7 exps.) The process was identical whether or not insulin had been administered, though the hypoglycemia in the latter case produced lower final levels. Since the equalization at the lower sugar level required the same amount of time, the sugar exchange was actually slower, as can be shown by injection of glucose simultaneously with the insulin. Whether insulin influenced permeability could not be decided, but if that occurred then it must make the marginal cell layer less permeable. An analogous process occurred when an isotonic glucose-Ringer sol., was introduced intraperitoneally. (5 exps.) The higher the blood sugar (with or without insulin, or insulin and glucose) the slower the drop in concentration in comparison to the blood. The accelerated action with insulin (hypoglycemia) may have been only one of equalization of concentration or the endothelial cells may have had an increased absorbability for glucose. Insulin, however, had the same accelerating effect on sols. of levulose and galactose (6 exps.), while sols. of mannose and lactose were unaffected by insulin (6 exps.). It is concluded that insulin reduces the partial concentrations of these first two sugars and not of the last two. This difference undoubtedly is biological rather than chemical, glucose, levulose, and galactose being those sugars most frequently absorbed by the blood from the intestinal tract. Their value in the body is not parallel to the insulin effect, however, the order here being levulose, glucose, galactose. The presence of insulin is not necessary for absorption of glucose since the sugar content of the organs of pancreatectomized dogs increases after administration of sugar. The first part of this study shows that sugar exchange between the blood and the abdominal cavity takes place by a simple diffusion process on the rapidity of which insulin does not act directly but only by its effect on the sugar concentration of the blood.

16226. **PSCHENITSCHNIKOW, W. J. Ueber die Alkalireserve des Blutes bei lokaler Infiltrationsanästhesie.** *Schmerz, Narkose-Anaesthesie* 3(3): 85-89. 1930. —In 30 patients determination before and 10 min. and 24 hrs. after operation showed no important changes in the alkali reserve, after the use of from 400 to 1600 cc. of .25% novocaine in Ringer's solution.

16227. **RAGINSKY, B. B., JAMES B. ROSS, and R. L. STEHLE. The action of pituitary extract upon blood pressure.** *Jour. Pharmacol. and Exp. Therapeut.* 38(4): 473-480. 1930.—The action of pituitary extract upon the blood pressure of the dog under chloretone, ether and luminal is described. Quantitative differences in response are ascribed to the dosage and to the particular anesthesia used. The rise in blood pressure is frequently complicated by a phase of depression, which the authors ascribe to a constriction of the coronary vessels. This effect is not abolished by double vagotomy.—*H. S. Wells.*

16228. **RAIZISS, GEORGE W., and M. SEVERAC. Chemotherapeutic studies concerning the penetration of organic compounds of arsenic into the cerebrospinal system.** *Arch. Dermatol. and Syphilol.* 22(6): 1031-1042. 1930.—Methods for producing the penetration of organic compounds of arsenic into the cerebrospinal system and the results obtained are described, also the effectiveness of these compounds when administered intravenously into animals inoculated intraspinally with trypanosomes or spirochetes. Control animals invariably showed the

presence of trypanosomes in the spinal fluid. Among the pentavalent arsenicals that the authors studied, the most effective trypanocide in the spinal fluid was arsanilic acid, but, owing to its lower toxicity, tryparsamide has the highest chemotherapeutic index (12). It is followed by amino-arsono-ethanol with an index of 9.1. Preliminary observations with spirochetes indicate that tryparsamide is less effective, acetarsone showing a better result. Microscopically, spirochetes could not be seen in the spinal fluid. No spirochetes were present in the spinal canal several days after intraspinal inoculation, as was shown by infection of normal rabbits with the fluid. No spirochetes were found by this method, either in the brain or the spinal fluid of a rabbit which was kept under observation for a year after the intraspinal inoculation. In the great majority of cases the spinal inoculation was followed by the development of scrotal and testicular lesions, in addition to generalized manifestations of syphilis.—*Authors' conclusions.*

16229. **RASTELLI, G., e A. CASAZZA. Sul meccanismo d'azione dello zolfo colloidale. [Action of colloidal S.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 939-942. 1930.—The more finely dispersed the S, the less is it reduced to H_2S by blood serum. Of the colloidal S intravenously administered a portion, which has undergone flocculation, is reduced to H_2S, while the strongly dispersed portion may exert its pharmacological action, and cause an anaphylactic-like shock.—*M. Comel.*

16230. **REED, C. I., and E. A. THACKER. The effect of intravenous and intraperitoneal injections of irradiated ergosterol.** *Amer. Jour. Physiol.* 96(1): 21-27. 1931. —In experiments on 14 dogs irradiated ergosterol, intraven. or intraperitoneally, was more effective than comparable doses by mouth. The alimentary tract protects to some extent against the toxic effects of large doses. Present available evidence indicates that the induction of toxic symptoms is not necessarily parallel with hypercalcemia. Present evidence does not indicate any constant effect of ergosterol when administered by this method on the concentration of inorganic P in the blood. Continued administration of a therapeutic dose of ergosterol may develop in the normal animal a certain degree of tolerance as indicated by the reduction of hypercalcemia. Hypercalcemia may persist for long periods after administration has been discontinued. After pronounced toxic symptoms were developed, none of the animals in this series recovered after discontinuance of administration.

16231. **REIMANN, HOBART A. The effect of the injection of colloidal substances on experimental typhus fever.** *Jour. Immunol.* 18(2): 153-158. 1930.—The administration of india ink, sodium chaulmoograte, trypan blue and collargol before the inoculation of typhus virus in guinea pigs usually prolongs the incubation time and shortens or diminishes the febrile reaction of typhus fever. The probable explanation of the results is discussed.—*Author's conclusions.*

16232. **RIDDER, C. Pentamethylentetrazol (Cardiazol). IV. Wird Cardiazol in der Leber entgiftet?** *Arch. Exp. Path. u. Pharmakol.* 120(1/2): 126-128. 1927.—Solutions of cardiazol perfused through the liver of cold or warm-blooded animals show no change in effective strength.

16233. **ROBINSON, ROBERT. Bakerian Lecture.—The molecular structure of strychnine and brucine.** *Proc. Roy. Soc.* [*London*] A 130(814): 431-452. 1931.

16234. **ROJO, DARIO J. Acción del Energéteno de Muérdago sobre tensión y coagulación sanguineas. [Action of mistletoe on blood pressure and coagulation.]** *Rev. Méd. Latino-Americana* 14(163): 767-773. 1929.—The work of A. Gaultier and Gréhaut who asserted the hypotensive action of mistletoe, as well as the opinions of therapeutic treatises, in contradiction with his own clinical experience, led him to this study. Mistletoe is described, the active principle of which is "guipsine." In the exps. "énergétène de gui" was used, for it contains all the active principles of the plant spawn and is uniform. The technique employed in the exps. is described. "Énergétène de gui" has the properties of elevating the blood pressure and of increasing the coagulability of blood.—*Author's conclusions* (*transl. by M. R. Freeland*).

16235. **RONCATO, A. Sull'iperglicemia curarica. II. Le riserve di glicogeno muscolare ed epatico negli animali curarizzati trattati o no con insulina. [On curaric hyperglycemia II. The reserves of muscular and liver glycogen in curarised animals treated and untreated with insulin.]** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 254-255. 1930.—Curarisation is accompanied by an increase of the muscle glycogen up to 40% more than in resting well fed animals. The liver glycogen decreases on the contrary by 20%. Insulin administration does not influence the curare hyperglycemia, nor the muscle and liver contents of glycogen. The author infers that curare does not prevent the absorption of blood glucose by the muscle, nor its polymerisation, but prevents the mobilisation of glycogen; and that curare acts also on the metabolism of the carbohydrates in the liver, probably raising the liminal value for glycogen formation by the liver cells, and thereby contributing to the production of hyperglycemia.—*M. Comel.*

16236. **RONNEFELDT, F. Amöbenruhrbehandlung mit Rivanol. [Treatment of amebic dysentery with rivanol.]** *Arch. Schiffs- u. Tropen-Hyg.* 35(3): 176-180. 1931.

16237. **RUGGIERI, ETTORE. Comportamento ed importanza del glutatione nella narcosi eterea, ed in altre anestesie. [Glutathione in ether narcosis and other anesthesias.]** *Arch. Ital. Chir.* 28(1): 69-87. 1931.—The glutathione in the blood in 21 patients operated on under ether narcosis was much diminished, sometimes for as long as 48 hrs. In 3 patients operated on under spinal and in 2 under local anesthesia there was a comparatively slight diminution of blood glutathione. The glutathione in the blood of a normal person was estimated; then 20 cc. of this blood was exposed in a test tube to ether insufflated through it. The glutathione was reduced from 15 mgm. % to 5.25 mgm. %. It is concluded that ether diminishes the amount of glutathione in the organism, not merely driving it from the blood into other tissues. This diminution is regarded as one probable cause of postanesthetic acidosis and hyperglycemia.

16238. **RUICKOLDT, ERNST. Vomicin, ein neues Strychnosalkaloid.** *Arch. Exp. Path. u. Pharmakol.* 149 (5/6): 370-380. 4 fig. 1930.—The 3rd alkaloid from Strychnos seeds, vomicin, was tested on rabbits, mice and dogs, and on isolated organs. In warm-blooded (but not decerebrate or decapitated) animals it was found to produce (given intravenously, not subcutaneously) clonic convulsions, apparently not of reflex origin, and easily controlled even from large doses; 12 times the convulsive dose was not fatal. The alkaloid had no especial effect beyond that conditioned by the convulsions on blood-pressure and respiration. The body temperature was depressed, except as occasionally the depression was masked by a rise in temperature produced by the severe convulsions. Even after excessive doses of the alkaloid it could not be detected in the urine and feces by the color reaction of Wieland and Oertel. This, together with the quick and complete recovery of the animals, indicates rapid destruction of the substance in the organism. In the frog vomicin produces convulsions of the picrotoxin type, which, however, cease on section of the central nervous system cephalad or caudad to the level of the tympanum. The isolated frog heart is reversibly paralyzed by vomicin; the frog rectum becomes non-motile. The intestine of warm-blooded animals, isolated or in situ, is paralyzed. Vomicin did not produce contractions in the isolated virginal guinea-pig uterus.—*Author summary* (*transl.*).

16239. **RUNGE, H. G., und H. SCHMIDT. Pantocain, ein vollwertiger Kokainersatz.** *Arch. Ohren-, Nasen- u. Kehlkopfheilk.* 128(3): 232-243. 1931.—Pantocaine is a novocaine derivative obtained by substituting a methyl for an ethyl group and a butyl radical for the amino. In 1% solution it was found to be as effective as 10% cocaine or 2% percaine, as toxic as 2½% cocaine or ½%

percaine, i.e., relatively less toxic. The effect lasted longer, particularly in infiltration and conduction anesthesia. In 95% of cases the 1% solution was adequate; 2% was used in the other instances. No tissue injury occurred (hemolysis experiments). It was water soluble, stable, and could be sterilized.

16240. **RUSSO, GIUSEPPE. L'azione dell'adrenalina sui vasi in presenza di aminoacidi. [Action of adrenalin on vessels when amino acids are added.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 488-489. 1930.—Glycine does not influence vasoconstriction by adrenalin.—*M. Comel.*

16241. **SABBATANI, L. Ricerche farmacologiche col permanganato di sodio per iniezioni endovenose. [Pharmacology of intravenously injected sodium permanganate.]** *Atti. R. Accad. Nazion. Lincei Cl. Sci. Fis. Mat. e Nat.* 7(2): 113-114. 1928.—The pharmacological action of this substance is identifiable with the general action of MnO_2. The minimum lethal dose of $NaMnO_4$ and of MnO_2 is, per kgm. of rabbit intravenously injected, 0.00023 gm. mols. Immediately after injection of $NaMnO_4$ it acts on the blood plasma and cells and on the endothelium of the vessels causing an intense hemolysis, hemoglobinemia, hemoglobinuria and anemia which is proportional, within certain limits, to the dose injected. The permanganate is reduced by the blood to colloidal MnO_2 which in turn, if large doses of permanganate be given, produces a general action depending on solubility factors. Just as the action of permanganate after the first moment is identifiable with that of colloidal MnO_2, so, finally, the action of this is identifiable with that of the products of further reduction formed in the animal from MnO_2, i.e., MnO.—*J. G. Edwards.*

16242. **SAITSU, RYUZO. Vergleichende Untersuchung über die pharmakologische Wirkung von Pelletierin und Pseudopelletierin.** *Nagasaki Igaku Kwai Zasshi (Jour. Nagasaki Med. Soc.)* 6: 154-164. 1928.—The two toxins act on the frog heart in vitro as well as on the rabbit intestine and uterus in vitro almost equally, qualitatively and quantitatively, but the toxicity of pelletierine is 10 times as great as that of pseudopelletierine for the cat tapeworm. Pelletierine always has a stimulating action on the earthworm muscle, while pseudopelletierine is paralytic.

16243. **SALOMON, H., und G. ZUELZER. Über das aus der Leber gewonnene Herzhormon "Eutonon."** *Zeitschr. Ges. Exp. Med.* 66(3/4): 291-324. 20 fig. 1929.—Eutonon caused an increased in rate and strength of beat in the Straub frog heart preparation. The harmful effects of acid and the inhibition by acetyl choline were overcome by "Eutonon" application. Increased tone of heart muscle, increased strength of beat, and increased coronary flow were noted in dog and cat heart preparations. There were no clinical contra-indications in any form of heart disease. Its use is recommended in all myocardial cases. 23 selected clinical cases are described. —*H. M. Krueger.*

16244. **SALOMONSEN, LEIF. Effects of insulin and epinephrine on the blood acetone in fasting children.** *Amer. Jour. Dis. Children* 40(4): 718-724. 1930.—In fasting children less than 3 yrs. of age an investigation was made on the effect of insulin and epinephrine on blood sugar, on blood acetone and on the content of fatty acids in the blood plasma during the hours immediately following the injections. In 8 experiments it was found that insulin reduces the blood acetone, but in decreasing degree according to the decrease of sugar in the organism. Epinephrine under the same conditions produces an increase in the blood acetone, the increase being greater in proportion as the organism is poorer in sugar. In 1 experiment, insulin effected a distinct decrease in the content of fatty acids in the blood. In 5 of 6 experiments, injection of epinephrine was followed by a rise in the quantity of fatty acids.—*Author's summary.*

Children* 41(3): 528-531. 1931.—Viosterol was administered to 40 infants from the 2nd to the 8th day of life and they were observed for 6 mos.; the number of young or single-lobed polymorphonuclears tended to increase and the older, multilobed forms decreased. Amount of dosage (3-48 drops daily) made little difference in the reaction. Return to normal after discontinuance of dosage was rapid.

16247. **SCAFFIDI, VITTORIO. Ricerche sull'antagonismo chimico. IV. Sul meccanismo determinante l'azione antagonista del bario e del magnesio sulla pressione arteriosa. [Mechanism of antagonistic action of Ba and Mg on arterial pressure.]** *Riv. Patol. Sperim.* 5(4/5): 371-383. 6 fig. 1930.—Arterial pressure is increased by Ba through its action on the vessels and on myocardial contractility. Mg lowers arterial pressure without acting markedly on the myocardium, through modification of the caliber of the vessels. In the antagonism between Ba and Mg the action of Ba prevails. —*M. Comel.*

16248. **SCHILLING, CLAUS, und SCHULZE. Wie wirkt Chinin bei Malaria?** *Deutsche Med. Wochenschr.* 56(2): 46-47. 1930.—The large molecule of quinine is changed in the body and broken down. The quinoline part of the molecule is active.

16249. **SCHULTZ, OTTO KARL, und WILHELM MEYER. Über die Parallelität zwischen antirachitischem und toxischem Faktor in bestrahltem Ergosterin. Ein Beitrag sur Standardisierung des Vitamin-D.** *Zeitschr. Kinderheilk.* 50(1): 84-95. 1930.—Irradiated ergosterol as Neuvigentol, Radiostal and Präformin in doses of 10-300 mgm. per kgm. was given to about 50 rabbits and doses up to 44 mgm. to 59 rats. In neither could tissue injury, or rise in inorganic P or Ca be elicited. Parallelism between the antirachitic and the toxic factor is not indicated.

16250. **SCHUMACHER, CARL. Tierexperimenteller Beitrag zur Abhängigkeit des Salvarsaneffektes vom Zustand des retikuloendothelialen Systems. (R.E.S.)** *Dermatol. Zeitschr.* 60(6): 469-476. 1931.—In an unstated no. of mice suffering from nagana or recurrent fever the reticulo-endothelial system was blocked with 0.25 cc. 20% Fe sugar solution per 20 gm. wt., some having previously been splenectomized; they were injected intravenously or subcutaneously with 1 cc. per 20 gm. wt. of 1:300 neosalvarsan or ½ cc. of 1:150. In both the blocked and the blocked and splenectomized mice the disease was more serious than in the controls and even moderate doses of neosalvarsan were toxic. With the 1:300 solution the arsenic level of the blood was lower than in the controls, which may have been due to the blocking or to the increased toxicity. In subcutaneous injection there was no particular difference in the arsenic level of the blood between test and control animals. The directly lethal action of the subcutaneous dose was 3 times that of the intravenous and the blocked animals were much more susceptible than the controls.

16251. **SECHI, ELIO. Influenza del catrame sulla formazione eteroplastica di osso nel rene di coniglio. [Action of tar on the heteroplastic formation of bone in the kidney of rabbit.]** *Riv. Patol. Sperim.* 5(1): 25-30. 1930.—When tar was injected into the kidney of a rabbit after ligation of the renal vessels, the heteroplastic bone formation was inhibited. This inhibition was observed also when tar injections were made after a treatment of the skin with tar had taken place previously. —*M. Comel.*

16252. **SERENI, ENRICO. La giunzione mio-neurale nei cefalopodi. [On the myo-neural junction in cephalopods.]** *Boll. Soc. Ital. Biol. Sperim.* 5(2): 77-82. 1930.—In cephalopods the zone between muscle and nerve shows peculiar properties, functional as well as pharmacological. Strychnine and other poisons have an elective paralysing action on it. Nicotine, pilocarpine and other poisons have on the contrary a stimulating action. The junc-

tion zone does not degenerate after cutting of the nerve fiber; weeks afterwards the action of nicotine is still present; the irritability is lost after months. Indirect stimulation follows in the most marked manner the action of guanidin, which has a paralysing action in vertebrates.—*M. Comel.*

16253. **SERGIJEWSKI, M. W., und P. F. TETERIN.** Die Reaktion des isolierten Herzens der kastrierten weissen Ratte auf Adrenalin. *Arch. Exp. Path. u. Pharmakol.* 149(3/4): 211-217. 1930.—Studies on the isolated hearts of 8 white rats showed that: The isolated heart of the normal rat responds to the injection of 0.5 cc. epinephrine 1:1,000,000 with increased amplitude and slight acceleration; that of the castrated rat, with accelerated rhythm and decreased or unaltered amplitude, but if the dose of epinephrine is increased, the reaction of the heart approaches normal. Feeding or injection of the castrated rat with dried testicular or prostatic tissue brought the heart reaction to epinephrine near normal; feeding or injection with powdered muscular tissue and prostate digested in gastric juice did not cause approximation to normal. No fatty infiltration could be determined in the heart of the castrated rat.—*Authors' abstract (transl.).*

16254. **SHAFER, GEORGE D., FRANKLIN J. UNDERWOOD, and EDMOND P. GAYNOR.** The action of amytal in impairing vagus cardiac inhibitory effects, and of ether in increasing the respiratory rate after its depression by amytal. *Amer. Jour. Physiol.* 91(2): 461-466. 1930.—Conclusions of Lieb and Mulinos that amytal rapidly impairs the effect of vagus stimulation upon the heart, and that it tends to depress the circulation are confirmed. After a time there is a gradual recovery from the impairment; however, in no case was this recovery complete while the dog was under amytal anesthesia. Stimulation of the vagus gives the greatest slowing of the heart in dogs not under the influence of any anesthetic (but decerebrate); the least slowing in dogs just completely under amytal anesthesia; and an intermediate degree of slowing when the animal is under ether anesthesia alone—or when it has been under amytal for about 2 hrs. or more. Stimulation of the intact vagus nerve of a dog whose inhibitory mechanism in the heart is almost paralyzed with amytal may cause a marked rise in blood pressure (instead of a fall) if the nerve stimulated happens to carry strong pressor impulses. Small amounts of ether either in the air breathed, or intraven., quickly increases the respiratory rate after it has been greatly depressed by amytal; and this effect of ether is shown not to be due to a reflex aroused by irritation of any part of the respiratory epithelium.—*Authors' conclusions.*

16256. **SIMONIN, CAMILLE.** Contribution à l'étude expérimentale de l'alcoolisme aigu. *Jour. Physiol. Path. Gén.* 28(3): 596-611. 6 fig. 1930.—Beverages of intermediate alcoholic content (10%) cause an increase in the alcohol content of tissues and fluids that is directly proportional to the quantity of alcohol ingested, and inversely proportional to the weight of the subject. Beverages of high alcoholic content (40-50%) raise the concentration of alcohol in the blood ½ to ⅔ above the theoretical value calculated on the basis of a beverage of intermediate strength. Beverages of low alcoholic content (3.5%) behave in the reverse manner. By spacing out the ingestions it is possible to keep the alcoholic content of the blood below the intoxication level, and yet insure that the tissues are continually exposed to alcohol. By frequently repeated ingestions it is possible to raise the alcoholic content of the blood above the value characteristic for a beverage of intermediate strength. The onset of alcoholic inpregnation appears within about 30 min. after ingestion, and is marked by a brief syndrome of attack, showing motor, emotive and labyrinthine effects. This may be of great medico-legal importance. The animals used were men, dogs and guinea pigs.—*W. R. Fearon.*

16257. **SMITH, DIETRICH C.** The action of certain autonomic drugs upon the pigmentary responses of Fundulus. *Jour. Exp. Zool.* 58(1): 423-453. 1930.—A study was made of the effects upon the dermal melanophores of *Fundulus heteroclitus* of certain drugs supposedly possessed of a specific action on parts of the autonomic nervous system. The drugs were injected into the body cavity. Fishes treated with cocaine, a sympathetic stimulant, showed no expansion of their melanophores when placed upon a black background, while ergot, a sympathetic depressant, produced a stellate condition of the melanophores regardless of the background. Pilocarpine and physostigmine, parasympathetic stimulants, favored contraction of the melanophores. With atropine, a parasympathetic depressant, injected fishes placed over a white background showed a stellate condition of their melanophores, though this drug did not prevent such fishes from becoming completely dark when they were transferred to a black background. Tests made of the responses of the trunk melanophores of ergotized and atropinized fishes to temperature changes showed that in ergotized fishes these cells reacted as if denervated, contracting in heat and expanding in cold, while in atropinized fishes they reacted as if innervated, contracting in cold and expanding in heat. The results of these experiments were taken as suggestive of a double innervation of the melanophores of fishes.—*Author (courtesy Wistar Bibl. Serv.).*

16258. **SMITH, MAURICE I.** A quantitative colorimetric reaction for the ergot alkaloids and its application in the chemical standardization of ergot preparations. [*U. S.*] *Public Health Repts.* 45(26): 1466-1481. 1930.—Based upon Van Urk's qualitative reaction of ergot alkaloids with para-dimethyl-amino-benzaldehyde a procedure has been evolved whereby these alkaloids can be estimated quantitatively by a colorimetric method. This chemical method also lends itself to the quantitative estimation of the ergot alkaloids in the fluid extract of ergot. A comparison of this colorimetric chemical method of assay with the physiological method of Broom and Clark as applied to several ergot alkaloids, both pure and impure, gave results which indicated good agreement. Agreement was also obtained when these methods were applied in the standardization of 5 fluid extracts of ergot.—*M. I. Smith.*

16259. **SORGE, G.** Sull'azione ipoglicemizzante del "tè di fagiuolo." [On the hypoglycemia following administration of "bean tea."] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 967-969. 1930.—Bean extracts in vitro had no action on the glucose content of glucose solutions. Administered per os to normal or diabetic subjects they markedly lowered blood glucose. The "hyperglycemic reaction" following adrenalin administration was also influenced when "bean tea" was administered with glucose.—*M. Comel.*

16260. **SPANIER, PHILIPP.** Ein Versuch, heterogene, ins Blut transplantierte Leukocyten als mechanisches Vehikel zwecks Transportierung therapeutischer Agenzien in die Lungen auszunutzen. (Eine experimentelle Studie.) *Beitr. Klin. Tuberk.* 73(2): 210-231. 9 fig. 1929.—In order to obtain from a therapeutic agent the maximum destruction of parasites with the least harm to the host, it is desirable to secure its fixation, in suitable concentration, directly in the organ which demands treatment. Spanier sought, on this principle, to find new means of introducing therapeutic substances that would tend to direct them toward the lungs. His hypothesis was that the lungs play an important part in cellular metabolism, filtering out foreign substances from the circulating blood and destroying exhausted leukocytes.

He first sought to determine the difference between the path followed by a substance introduced directly into the circulating blood, and that followed by the same substance subjected to phagocytosis by leukocytes, and then introduced, borne by these foreign leukocytes, into the circulation of another animal. He injected an abscess in a dog with a 2% trypan blue solution. Blue leukocytes obtained from the abscess were washed and injected into the ear vein of 1 rabbit and the right heart of another. In the first rabbit blue cells were found in numerous small pulmonary vessels, but nowhere else, nor was there any blue coloration of the urine. In the rabbit injected in the heart the capillaries of the lungs were found teeming with blue leukocytes; there were a few in 1 or 2 of the large vessels of the liver but nowhere else. In a 3d rabbit injected in an ear vein with trypan-blue solution (without leukocytes), the oral mucosa, the skin of the ear, the lungs, liver, kidneys, supra-renals, testicles, and spleen were all colored. The question whether leukocytes would absorb therapeutic substances as well as dyes was next studied. Leukocytes from an abscess in a dog were found to take up 3 different Fe salts, Zn (pulv.), $BaSO_4$ and bismuth subnitrate. The path of phagocytosed therapeutic substances carried into the organism by foreign leukocytes was then studied, histologically in the case of Fe, chemically for I, and radiographically for bismuth subnitrate. Leukocytes from a dog laden with an Fe salt solution were injected into ear veins of 2 rabbits. Stained sections showed Fe particles only in the lungs. A similar Fe salt solution was injected into an ear vein of another rabbit. Stained sections showed quantities of Fe particles in the reticulo-endothelial tissue of the spleen and in Kupffer's stellate cells in the liver, less abundantly in the kidneys and sparsely in some alveoli of the lungs. In the chemically studied group, 1 rabbit received in an ear vein 3 cc. of Lugol's solution with 6 cc. isotonic NaCl solution, and another the same amount of Lugol's solution shaken with 3 cc. leukocytes and NaCl solution. Quantitative analysis of the lungs, liver, spleen and kidneys showed that the rabbit which received Lugol's solution alone retained after 5 minutes 0.42% of the injected I, chiefly in the liver, while the rabbit which received Lugol's solution with leukocytes retained 15.05% I, chiefly in the lungs. In a 3d series, in which roentgenograms were taken before and after injection, 4 dogs received injections of $BaSO_4$ and leukocytes in the vena saphena; 2 showed no changes in the lung, 1 showed, 10 min. after injection, little spots, and 1 showed, 60' after injection, a shadow 2-3 cm. broad in the region of the hilum of the left lung; a control dog injected with $BaSO_4$ without leukocytes, showed no changes. A 6th and 7th dog were injected with bismuth subnitrate, respectively with and without leukocytes. The first died under injection, yet showed numerous dark foci in the lungs that had not been there before injection, while the control, which survived, showed no focal changes 6' after injection. No attempt was made to study the therapeutic action of substances introduced through the agency of leukocytes, but the suitability of such means for the treatment of pulmonary tuberculosis is suggested.

16261. **[SPIELBERG, G. I.]** ШПИЛЬБЕРГ, Г. И. К вопросу о влиянии кальция на желудочную секрецию. **[Influence of calcium on gastric secretion.]** [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 197-201. 1930.—Gastric juice was extracted from the stomach, every 10 min. after breakfast. Then $CaCl_2$ sols. were injected intraven., and gastric juice examined again several times. As a result, acidity of the stomach contents was increased. This increase was more pronounced in hyperacid patients, and less so in normally acid and hypoacid ones. Increase of acidity is observed 10-20 min. after the injection of Ca.—*B. Van Rosen.*

16262. **SPIES, TOM DOUGLAS. The calcification of tubercles by means of irradiated ergosterol.** *Amer. Jour. Path.* 6(3): 337-346. 1 pl. 1930.—The administration of repeated large doses of activated ergosterol to rabbits suffering from acute tuberculosis causes extensive deposition of Ca salts within the caseous lesions. The administration of a single large dose produces no demonstrable changes. It is suggested that a high vitamin D diet might possibly be useful in some cases of pulmonary tuberculosis.—*Author summary.*

Med.* 15(1/2): 119-134. 1930.—Definite amounts of various hormones were injected intraven. into rabbits and the change in the colloid osmotic pressure determined as by Krogh and Nakazawa. Thyreoglandol temporarily increases the osmotic pressure due probably to a qualitative change of the blood proteins. Pituitrin decreases the osmotic pressure. Insulin and adrenalin at first increase, then decrease the osmotic pressure.—*J. M. Johlin.*

16268. **TANIUCHI, YOICHIRO, und TETSUICHI KIYOHARA. Über die antagonistische Wirkung des Atropins gegen die Adrenalinzuckermobilisierung in der Leber.** *Folia Pharmacol. Japonica* [In Japanese] 8(3): 214-226. 1930.—In perfusion of the toad liver atropine limited sugar mobilization by epinephrine. Atropine action was greater with longer previous stimulation by epinephrine. This finding agrees with the earlier result of Lidth du Yende and Ueda that there is an antagonistic action between atropine and epinephrine, and contradicts the finding of Goharas that atropine is a fatigue poison of the sympathetic nerve ending.

16269. **TAYLOR, F. H. L., and A. G. YOUNG. Biochemical studies of mercury compounds. I. The effect of acids, bases, salts and blood serum on the diffusion of mercury compounds in vitro.** *Jour. Pharmacol. & Exp. Ther.* 38(2): 217-229. 1930.—In vitro studies of the diffusion of mercury compounds across collodion mem-

branes show that: Acids, as represented by $N/100$ HCl, increased the diffusion of inorganic Hg compounds, while bases, as represented by $N/100$ NaOH, increased the diffusion of organic Hg compounds. KI had the effect of greatly increasing the diffusion rate of all the compounds of Hg studied except K mercuritetraiodide. Chloride showed no specific action on the diffusion of Hg compounds due to the Cl ion, but acted in the same way as HCl but to a lesser extent. NH_4Cl greatly increased the diffusibility of the double salt of Na oxymercuri-o-chlorophen-oxyl acetate with diethyl barbituric acid ("novasurol") and the Na salt of Hg salicylallylamide-o-acetate ("salyrgan"). NH_4Cl acted with the other compounds studied, as an acid precursor in the same manner and degree as $CaCl_2$. The inorganic compounds of HCl represented by $HgCl_2$, K-mercuri-tetraiodide and metallic Hg showed a considerable amount of diffusion into blood serum, while the organic compounds "novasurol" and "salyrgan" showed only a small amount in the same time. Hg succinimide occupied an intermediate position. A table of solubilities of water insoluble Hg compounds in blood serum is given.—*Authors' summary.*

16270. **TEMPLETON, H. J., B. M. RIX, and ROBERT THOMSON. Absorption rate of bismuth compounds.** *Arch. Dermatol. and Syphilol.* 21 (5): 739-755. 1930.—X-ray studies were made of the absorption rate of 17 different Bi preparations in 114 patients. The absorption rate of 15 of these was also determined in 15 rabbits. The absorption rate in the rabbit was frequently so much slower than in man that the authors conclude that absorption studies should be made on patients, not on experimental animals.

16271. **THAYSEN, TH. E. HESS. Clinical investigations into the effect of intravenous injection of insulin. III. The blood sugar curve in diabetics.** *Acta Med. Scandinavica* 73 (5): 408-424. 1930.—In 21 diabetics the blood sugar curve is examined after intraven. injection of 12 units of insulin. In the mildest cases the form of the blood sugar curve is normal; the more severe the case, the more abnormal the curve, as both the assimilation line and the restoration line are flattened and presenting certain irregularities in their course. The flattening of the assimilation line is due to the lowest blood sugar value coming later in diabetics than in normal individuals, this delay increasing with the severity of the case. Thus the assimilation takes longer in diabetics than in normal individuals, even when the initial blood sugar value in the diabetic is normal. Only the mildest cases of diabetes show a definite distinction between the primary rise and the secondary rise of the restoration line. The assimilation index varied from 2.1 to 0.3. It is independent of the initial blood sugar value and of the presence or absence of acidosis, and is not influenced by 3 days' fasting (+300 gm. vegetables). The lower the assimilation index, the more severe the case seems to be. In dividing the material in 3 groups it is found that patients with assimilation index 2.1—1.1 were able to assimilate an adequately carbohydrate-rich and calorific diet without insulin. In this group were 5 cases of adiposity which called for a lower supply of calories than usual. On a similar diet, patients with assimilation index 1.0—0.7 required a moderate supply of insulin to keep the morning urine free of sugar and acetone, while patients with assimilation index 0.7—0.3 required a considerable amount of insulin. Within each of these groups there are individual variations in the relation between assimilation index and tolerance. The corresponding features of the blood sugar curve in normal individuals are illustrated by the findings in 60 examinations on 50 non diabetic individuals.—*Author's summary.*

16272. **TOMMASELLI, ANTONIO. Ricerche sull'azione del colato di sodio sulla funzione motoria dell'utero. [Action of Na cholate on the motor function of uterus.]** *Riv. Patol. Sperim.* 5 (6): 522-526. 2 fig. 1930.—Na cholate exerts a very toxic action on uterine smooth muscle, in which complete paralysis is produced even by very dilute solutions (1:30,000) of cholate.—*M. Comel.*

16273. **TRAINA, S. Importanza dei riflessi naso-faringo-laringei sulla inibizione respiratoria e cardiaca. Condizioni che possono favorire la morte improvvisa all'inizio della narcosi cloroformica. [The importance of the naso-pharyngo-laryngeal reflexes in respiratory and cardiac inhibition. Factors which may favor sudden death in the initial stages of chloroform narcosis.]** *Arch. Fisiol.* 28 (3): 503-536. 20 fig. 1930.—The reflexes obtained by local stimulation of the mucous membrane of the nose, pharynx, larynx, trachea and bronchi were systematically studied using as a stimulus chloroform administration. Cardiac inhibition is more certainly obtained if the chloroform vapors act simultaneously on the nose and larynx: the nasal mucosa elicits more intense reflexes. Those elicited from the pharynx are very weak; weaker yet are those from the trachea. If chloroform vapors act in strong concentration on the nasal mucosa the gravity of the respiratory and heart reflexes arising is increased and sometimes is such as to lead to the death of the animal (rabbit). In bilaterally sympathectomised rabbits if electrical stimulation of the vagi is accompanied by chloroform inhalation death often follows. Intravenous injections of strong doses of adrenalin elicit frequently fibrillation of the auricles and then administration of chloroform is followed by death. When the spinal cord is cut below the point where the phrenic nerve originates, the rise of pressure commonly caused by chloroform inhalation is not produced. The author was not able to demonstrate any fact to corroborate the view of a functional antagonism between the upper respiratory tract (nose and pharynx) and the lower part (trachea and bonchi).—*M. Comel.*

16274. **TROISE, EMILIO. Estudio farmacológico sobre la ponzoña de la araña Latrodectus mactans. II. [Pharmacology of spider venom. II.]** *Rev. Soc. Argentina Biol.* 5 (8-9): 605-615. 1929.—**Especificidad del suero contra la araña Latrodectus mactans. [Anti-latrodectus Serum.]** *Rev. Soc. Argentina Biol.* 5 (8-9): 616-620. 1929.—This venom is highly toxic for the guinea-pig, almost non toxic for the toad. It is destroyed by potassium permanganate, by heating between 70°-100° C.; attenuated at 50° C. It dialyzes slowly, does not raise blood-pressure as previous samples did, produces hyperglycemia, polyglobulia while diminishing the white cell count. It does not contract isolated uterus, intestine nor the bronchi in situ. Applied locally it produces convulsions in striated muscle. It produces marked symptoms of central nervous origin. The convulsive tremor is due to the spinal cord and increases on decapitation; it does not occur in pithed animals (frogs and dogs). The serum of immunized rabbits protects against injection of fatal doses in the proportion of 0.01 cc. serum for 1 mgm. venom, and direct spider bites. This action is specific for this venom and does not affect that of other species such as *C. nigriventer.* Reciprocally antinigriventer serum is inactive for *L. mactans* venom. The precipitin value of the serum was low, not more than 1%.—*J. T. Lewis.*

16275. **TSKIMANAURI, G. Zur Pharmakologie des Plasmochins.** *Arch. Schiffs- u. Tropen-Hyg.* 35 (2): 89-97. 1931.—Plasmochin may be classed as a paralyzing toxin, which primarily affects the central nervous system, particularly the medulla. In therapeutic doses (0.3 mgm. per kgm.) the blood pressure increases and breathing accelerates and deepens. With increase of dosage the blood pressure falls, and breathing becomes labored. The heart is relatively resistant to the drug. In therapeutic doses it is not harmful.—*E. C. Faust.*

16276. **URCHS, O. The treatment of amoebic dysentery with acridin dyes.** *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 512-516. 1927[1928].—From experimental results it was concluded that: 2-ethoxy-6-9-diaminoacridinlactate was clinically and experimentally proved a specific against *Entamoeba histolytica* and diseases caused by this parasite. This compound is a very powerful anti-spasmodic, useful in related symptoms of the intestines.—*Author's conclusions.*

16277. VALENTI, A. Sulla farmacologia della chinazoline. [Pharmacological studies on chinazolins.] *Biochim. e Terapia Sperim.* 17(2): 84-96. 1930.—6-methyl-3-tolyl-3, 4-dihydrochinazolin, and its compounds with the methyl, ethyl, propyl, allyl and β-oxyethyl groups are stable basic substances, scarcely soluble in water even as chlorine salts. They have similar chemical and pharmacological properties; are scarcely toxic even when administered subcutaneously or intravenously. 0.035 gm. per kgm. intravenously produces hemolysis and forms methemoglobin. Toxic symptoms arise chiefly from the nervous system, whose centers they depress, causing localised muscular contractions and tremor. The heart rate slows and the arterial pressure falls.—*M. Comel.*

16278. VELICOGNA, A. Sull-azione dell'Adonis vernalis sul sistema organo-vegetativo. [Action of Adonis vernalis on the autonomic system.] *Gazz. Ospedali e Cliniche* 51(49): 1556-1560. 1930.—The action of *A. vernalis*, studied by the method of Eppinger and Hess in 6 cases, consisted of a slight bradycardia which probably was not due to an exciting action of the parasympathetic.

16279. VELLARD, J. Propriétés des sécrétions cutanées de quelques rainettes des environs de Rio de Janeiro. *Compt. Rend. Acad. Sci.* [*Paris*] 188(16): 1064-1066. 1929.—The cutaneous secretions of *Hyla faber, H. albomarginata, H. crospedopsila, Trachycephalus nigromaculatus,* and of the skin and parotid glands of *Phyllomedusa burmeisteri* were studied to determine their toxic properties. Those of *H. faber* and *H. crospedopsila* were completely atoxic; that of *H. albomarginata* had a faint toxic reaction, but was not fatal to pigeons, while those of the other 2 species, though differing from each other, were decidedly toxic. Their properties are described.

16280. VIALE, G., e T. COMBES. Colina e ghiandola surrenale. [Choline and suprarenal glands.] *Arch. di Fisiol.* 28(1): 25-32. 1930.—Following injection of a sympathicotropic drug, as adrenalin, the organism reacts by emission into the blood of an antagonistic, i.e., vagotonic substance, such as cholin. This cholin comes from the suprarenal glands. Vagotomy, above the diaphragm, does not exercise any action on the choline content of the cortex of suprarenal gland.—*M. Comel.*

16281. [VORONTSOV, V. N., and V. ÏŪ. LESHCHINSKIĬ.] ВОРОНЦОВ, В. Н., и В. Ю. ЛЕЩИНСКИЙ. Изменение величины зрачков у животных под влиянием наркоза. III. Морфийно-хлороформный наркоз собак, кошек и кроликов. [Change in the size of the pupils of narcotized animals. III. Morphine chloroform narcosis in dogs, cats and rabbits.] Труды Научно Исследовательского Института при Воронежском Государственном Университете (*Trav. Inst. Rech. Sci. Univ. d'État, Voronèje, U.S.S.R.*) 1929(3): 111-120. 1929.—The reactions of the pupils of various animals to combined morphine-chloroform narcosis are not the same. In dogs, dilatation of the pupil is rare. Almost invariably there is a steady contraction. In cats there is almost invariably a steady dilatation of the pupil. The degree of this dilatation in combined morphine-chloroform narcosis is somewhat less than in chloroform. Apparently the combination of morphine with chloroform does not increase the narcosis reaction of the pupil in the cat. In rabbits dilatation is most common; a scarcely noticeable contraction sometimes occurs. Dilatation in the rabbit eye is as a rule not constant; fluctuations occur, contrasting with the regular dilatation observed in chloroform narcosis. The amplitude of the dilatation of the rabbit pupil under combined morphine-chloroform narcosis is somewhat greater than in the ordinary chloroform narcosis.—*Authors' summary (transl.).*

16282. WADA, HIRATAKE. Klinische und experimentelle Untersuchung über die durch Giftraupe, Dendrolimus spectabilis, verursachte Dermatitis. V. Untersuchung über die pharmakologische Wirkung des Stichhaargiftes. *Chiba Igaku Kwai Zasshi* (*Mitteil. Ges. Chiga*) 6: 373-389. 1928.—The toxin, not yet obtained pure is grayish-white or yellowish in color, hygroscopic, not bitter to the taste, easily dissolves in water, scarcely soluble in absolute alcohol, ether, chloroform, benzol, and amylalcohol. It did not show an alkaloid or N reaction, and did not reduce Fehling's sol. The lethal dose for mice per 10 gm. body wt. was 0.005 gm. in subcut., 0.004 gm. in intraperitoneal, and 0.002 gm. in intraven. injection. In somewhat larger doses it produced only a transient rise in blood pressure of the rabbit. In Laewen-Trendelenburg preparations it contracted the vessels and caused increased action of the isolated heart.

16283. WATKINS, O., and GEORGE VAN S. SMITH. Biochemical studies on the effect of adrenalin upon the nitrogen metabolism of rabbits. *Amer. Jour. Physiol.* 96(1): 28-34. 1931.—The usual dose was 1 cc. of 1:1000 sol. of adrenalin chloride, 128 injections being given in all, 55 subcut. (blood sugar rises in every instance, blood urea rises in 12 exps. in which determinations were made), 69 intra-abdominal (blood sugar rises in 49 instances, blood urea increases in 12 rabbits in which results were followed for 6 or more hrs.); similar results from intramuscular injection. There was no retention by the kidneys, as shown by urine analyses during prolonged exps. in which repeated injections of adrenalin were given. There was, in fact, some indication of an increased excretion of urea. It is concluded, therefore, that the rise in blood urea is a result of some catabolic action of adrenalin upon protein metabolism. The intraven. administration of glucose after injection of adrenalin does not affect the rise in urea. The administration of glucose and insulin after adrenalin exaggerates and prolongs the urea rise.

16284. WALSH, E. L., and A. C. IVY. Gall bladder visualization and jaundice. *Proc. Soc. Exp. Biol. & Med.* 28(4): 382-383. 1931.—Tetra-iodophenolphthalein persists in the gall bladder (dog), after ligation of the common bile duct, for at least 2 weeks; this confirms Copher's findings. Prior (60-96 hrs.) ligation of the common bile duct (dog) delayed the visualization of the gall bladder. Ingestion of meals did not cause disappearance, or decrease density, of the shadow.

16285. WEBER, LEONARD F. A list of cutaneous irritants. *Arch. Dermatol. and Syphilol.* 21(5): 761-770. 1930.

16286. WEISS, ST., und B. PAUL. Vegetatives Nervensystem und Lipoide. *Zeitschr. Ges. Exp. Med.* 60 (5/6): 702-708. 3 fig. 1928.—The authors studied the response to adrenalin injection in animals before and after cholesterol feeding. They used an oil suspension of Merck cholesterol, administered in some instances intramuscularly and in others per os in 14 human beings. This was followed by the administration of .02 mgm. of adrenalin. Blood pressure was measured every 15 sec. A depression of the adrenalin effect in the individuals receiving cholesterol either intramuscularly or per os was noted. It was concluded that the tonus of the vegetative nervous system can be influenced by the administration of a lipid.—*D. Perla.*

16287. WENNER, W. F., and E. W. BLANCHARD. Effect of intravenous injections of alkali on physiological action of curare. *Proc. Soc. Exp. Biol. & Med.* 26 (3): 182-183. 1928.—Preliminary paper. Intravenous injection in dogs of 3.0 gm. $NaHCO_3$, 8-10 min. after intravenous injection of 5.7 mgm. per kgm. body weight of curare, led to complete recovery within 15 min.

16288. WENNER, W. F., and E. W. BLANCHARD. Effect of intravenous injection of alkali on the action of curare. *Amer. Jour. Physiol.* 91(2): 563-566. 1930.—Exps. on 19 dogs indicate that alkali intraven. decreases the action of curare. Dogs completely recovered from the effects of curare after receiving intraven. injections of $NaHCO_3$. Acids augment the action of this drug. At the 1st appearance of paralysis the pH and CO_2 capacity of the blood begin to fall. Introduction of $NaHCO_3$ not only corrects anoxemia but also neutralizes the curare effect at the myoneural junction. The levels of serum Ca and P are not affected by curare. Sufficient quanti-

ties of Ca intraven. also inhibit the action of curare. The results of these experiments are in agreement with Burridge in regard to the effect of H ion concentration and calcification of the synapses upon the excitability of the nervous system.

16289. WILDE, B. de VOS-de. Mouvements rhythmiques spontanés du canal stomaco-intestinal de l'Eledone moschata Lam. *Arch. Néerland. Phys. Homme et Animaux.* III. C. 15(1): 97-113. 8 fig. 1930.—When suspended in aerated sea water isolated segments of the 3 parts of the gastro-intestinal tract of *E. moschata* show spontaneous rhythmic movements which are more distinct with the stomach and esophagus than with the terminal intestine. With filling of the stomach the movements are increased with increased tension on the walls and may continue for several days. Movements of the intestine are more pronounced when it is empty. Phenol stimulates movements of the esophagus, stomach and intestine, although only in the intestine can an increase in tonus be demonstrated. Nicotine causes movements of the esophagus and intestine to cease; those of the stomach reappear after an initial inhibition. The tonus is increased only in the intestine; this increase is transient, lasting not more than 20 min. Pilocarpine excites only the esophagus and stomach, although there is a small increase in tonus in all sections. Very low concentrations of atropine strongly stimulate the esophagus, stomach and intestine but only in the stomach is a slight increase in tonus demonstrable. The effects of atropine and pilocarpine are not antagonistic as has been frequently stated. Their action is not cumulative and when one adds a solution of pilocarpine to one of atropine there is an augumentation of tonus equivalent only to that with pilocarpine alone. Adrenaline exerts a stimulating effect only in the stomach. The tonus increases but slightly. $BaCl_2$ has an exciting effect on the stomach. The tonus gradually increases so as to make rhythmic contractions impossible. There is only a partial analogy between action of drugs on the intestines of *Eledone* and of vertebrates.—*Author's summary (transl. by C. S. Robinson).*

16290. WILDER, ROBERT L., and F. W. SCHLUTZ. The action of atropine and adrenaline on gastric tonus and hypermotility induced by insulin hypoglycemia. *Amer. Jour. Physiol.* 96(1): 54-58. 1931.—Hypermotility produced in the stomach of a fasting gastric-fistula dog by the subcutaneous injection of insulin was inhibited, and the increased tonus was lowered by giving atropine in physiologic dosage. This effect was not accompanied by any increase in the blood sugar. Adrenaline hydrochloride, injected intravenously during gastric hypermotility accompanying hypoglycemia, caused a lowering of tonus and inhibition of the active stomach contractions. This effect was not due to increase in blood sugar. The experimental results suggest the possibility that the hypertonicity of the starving infant may be due to an increased central nervous irritability caused to some extent by an existing hypoglycemia.

16291. WOOD, W. A. Experiments on the treatment of parasitic gastritis in sheep and lambs. *Jour. Agric. Sci.* [*Cambridge*] 20(2): 186-205. 1930.—The experiments have failed to reveal a reliable treatment for parasitic gastritis of sheep other than that caused by H. contortus, but confirm the experiments of other workers in that there are several drugs available which are more or less effective against this worm. Carbon tetrachloride, given in 12 c.c. doses would seem to be effective against Haemonchus. Tetrachlorethylene (Nema) given in capsules containing 5 c.c. gave, in most cases, good results against Haemonchus. Bunostomum trigonocephalum were found in 3 animals after the administration of this drug, which does not appear, therefore, to be effective for hookworm in sheep. The results so far obtained with petroleum ether seem promising but further trials are necessary before any definite conclusion can be arrived at. Turpentine, chloroform and linseed-oil mixture, chloramine T., sodium pentasulphide, arsenic and monsol do not appear to be effective. A proprietary Cu and As mixture, and Cu with As and HCl would not appear to have any advantage over Cu alone. Gow's tobacco powder (which is said to be composed of tobacco with 33% of S) gave promising results, but tobacco alone, S alone, and tobacco and S in the same doses and in the same proportions as in Gow's powder, did not produce any decrease in the egg count. The poor results obtained from drugs mixed with the food are disappointing, as this method of administration would be extremely useful in the treatment of large flocks of sheep.—*From author's summary.*

16292. ZAGAMI, V. Contributi alla conoscenza dell'azione dell'insulina, con particolare riguardo alla sindrome ipoglicemica. [Studies on the action of insulin, and especially on the hypoglycemic syndrome.] *Arch. Fisiol.* 28(3): 339-371. 1930.—Insulin acting on the sensory and motor regions of the cortex (in dogs and rabbits) does not elicit any noticeable motor or sensory response, nor does the threshold of excitability vary. When acting on the 4th ventricle (posterior surface of its base) no motor or sensory responses are elicited. The blood sugar content showed in this case a gradual decrease. When acting on the posterior surface of the lumbar enlargement of the cord in pigeons, insulin did not elicit any motor response but a temporary depression of touch and pain sensation was observed; the plantar reflex was also weakened. Following subdural injection of insulin in amounts not sufficient to elicit convulsions if administered subc. no motor or sensory response resulted. The glycemic curve was not different from that after subc. administration.—*M. Comel.*

16293. ZIEGLER, EDWIN E. The specific effect of bile salts on pneumococci and on pneumococcus pneumonia. *Arch. Internal Med.* 46(4): 644-656. 1930.—Na taurocholate in NaCl sol. produced lysis of pneumococci (Neufeld's phenomenon) in vitro within 2 hrs. in solutions as low as 1:25,000; in serum the bile salts acted more slowly than in NaCl sol. The bile salts were about ½ as lytic for erythrocytes as for pneumococci. No interference with antibody action of specific serums on pneumococci was evident. Used intraven. in 3 cases of lobar pneumonia, the bile salts produced no toxic symptoms, bradycardia or hemoglobinuria; they seemed to exert a specific action on the pneumonia, but tended to damage and obliterate the veins and to produce slight anemia.

16294. ZIPF, K., und E. WAGENFELD. Über die pharmakologische Wirkung des frisch defibrinierten Blutes. I. Mitteilung. II. Mitteilung: Darstellung und Wirkung des wirksamen Prinzipes. *Arch. Exp. Path. u. Pharmakol.* 150(1/2): 70-90; 91-105. 1930.—(I.) Doses of 1-3 cc. freshly defibrinated rabbit blood more or less lowered blood-pressure. Parallel with its action on the blood-pressure, a dilatation of the vessels supplying the cutaneous muscles, a contraction of the vessels in the splanchnic region, and an increase in lung volume were found. Small doses of defibrinated blood increased the heart amplitude, increased the volume of the right ventricle, decreased the volume of the left ventricle, but had no appreciable effect on the frequency of the heart beat. Small doses of defibrinated blood had no appreciable effect on the respiration; large doses paralyzed the respiratory center. Freshly defibrinated blood acted as a capillary poison. Neither atropin nor bilateral vagotomy prevented defibrinated blood from lowering blood-pressure. Suprarenin and the pressor substance of the hypophysis either inhibited the blood-pressure lowering action of defibrinated blood or increased blood-pressure. Histamin did not influence the action of freshly defibrinated blood. The action of defibrinated blood on blood-pressure probably was due to its effect on blood flow through the lungs. The active principle of freshly defibrinated blood was not histamin but a histamin-like substance.—(II.) The active principle of freshly defibrinated rabbit blood was prepared by 3 methods of deproteination, namely:—precipitation with $Fe(OH)_3$ dialysate; precipitation with Congo-red

and HCl; and ultra-filtration. The filtrate prepared by each of these methods had the same action on blood-pressure and a similar action on the entire circulation as had defibrinated blood. The active principle was water soluble, but insoluble in absolute alcohol and ether. After heating it was soluble-neutral, strongly alkaline, or strongly acid: long heating at above 70° C. destroyed it. The active principle was neither cholin nor histamin but a cholin-ester. Apparently its activity was due to an imidazol or a pyrrol ring.

16296. AKAIWA, HACHIRO, and MITSUZO TAKESHIMA. The reaction of lymphoid tissue to roentgen radiation. *Amer. Jour. Roentgenol.* 24(1): 42-46. 12 fig. 1930.—Rabbits weighing about 2 kgm. each were used; one knee of each was irradiated and the other used as a control. Four series of exposures were made: 1 with ¼ S.U.D. [skin unit dose]; 1 with ½ S.U.D.; 1 with 1 S.U.D.; and 1 with 2 S.U.D. The animals were killed at various periods of from 30 min. to as long as 3 wks. after irradiation. In another series the effect of continuous irradiation was studied: a knee on one side was exposed to ½ S.U.D. once a day for 5 days and in another series once a day for 10 days. Results indicate that reaction of lymphoid tissue of the rabbit to radiation can be divided into 3 periods: an early period consisting of the 1st 12 hrs., a middle period extending from 12 hrs. to 5 days, and a late period following the 5th day. In the early period are noted: increase in size of the lymph node, nuclear disintegration and decomposition of the germinal centers. Accompanying this some of the phenomena of inflammation are seen; cellular infiltration, congestion and exudation. Mitoses are seen during this period only when a small dose of x-rays is used. This evidence of regeneration is not present when the large dose is used. The middle interval is devoted mainly to phagocytosis and the clearing up of cellular débris. At the late stage there is fibrosis of the lymph node. The degree and rapidity of these above-mentioned phenomena are in proportion to the dose used. On the control side the reaction is much less and much slower than on the irradiated side, although otherwise it is the same.

16297. ALBANESE, A. Sulla dolicostenomelia. *Arch. Ortopedia.* 47(2): 539-573. 14 fig. 1931.—"Dolichostenomelia," observed by x-ray in a girl of 13, consisted of supernumerary cartilaginous zones of growth in the first metacarpals, the first metatarsals, and certain phalanges. Operation on the feet made possible histologic study. Many things indicated alterations in the germ plasm affecting exclusively the tissues of mesenchymal origin; the findings sustain the concept of "hyperchondroplasia" advanced by Mery and Babonneix.

16298. ALLEN, F. M. B., and H. I. McCLURE. A method of study of intracranial haemorrhage in the newborn infant. *Arch. Dis. Childhood* 6(32): 37-100. 3 fig. 1931.—Injection of "Röntyum (Kahlbaum)" into the cerebral vessels at necropsy gives radiograms with the finest possible detail.

16299. ALVAREZ, RAFAEL GONZÁLEZ. Acerca de la estructura curiosa de dos tumores quísticos de la cerda. [Curious structure of two cystic tumors of the sow.] *Rev. Hig. y Sanidad Pecuarias* 20(4): 317-321. 3 fig. 1930.—Two animals killed in the abattoir, previously castrated, presented neoplasms in the abdominal cavity, about the seat of operation, adherent to the muscle wall on the left side. They weighed about 500 gm., were cystic and surrounded by a layer of white tissue similar to all cavity linings. Section showed the tumors to be multilocular cysts, filled with a viscous liquid, and varying in diameter from 2 to 6 cm. None was entirely isolated from the others. Histologically, the cysts were lined with stratified epithelium. Small cavities contained papillary processes. In the wall of some of the cavities were large cellular nests of a yellow color, arranged in masses or cords, forming irregular spaces, most of which were empty, though some contained red blood corpuscles. These cells were large, cuboid, with a round nucleus containing powder-like chromatin and some large granules. Sudan III revealed fatty inclusions in some cells. Some of the cells, also, were bi-nuclear, and tended to form a syncytium. The author failed to find any reference in the literature to similar tumors. He considers the possibility of ovarian origin, or that they may be rests of the germinative epithelium of the Wolffian bodies (disembriomas).—*A. E. Taft.*

16300. BARONE, V. Mielosi eleucemica eosinofila. [A myeloid aleukemic eosinophilia.] *Haematologica 1. Arch.* 11(6): 437-448. 1930.—The case was characterized by tumefaction of lymph nodes, spleen and liver, the respective organs showing myeloid infiltrations. A secondary anemia obtained. While the white cell count was normal, the leucocytic formula comprised many immature white and red cells and an extremely high ratio of eosinophils (40-19%). The majority of eosinophils were mature forms, only 3-4% being myelocytes. At autopsy the eosinophilia was found to be generalized. No evidence was forthcoming that the case was due to constitutional inheritance, to dermatitis or to worm infection. The author accordingly interprets the eosinophilia as a peculiar form of myelopoiesis.—*N. A. Michels.*

16301. BELL, E. T., and B. J. CLAWSON. Experimental glomerulonephritis in a monkey. *Amer. Jour. Path.* 7(1): 57-62. 2 pl. 1931.—A form of chronic diffuse glomerulonephritis, produced in a monkey by repeated intravenous injections of streptococci over a period of 4 yrs., is characterized by marked increase in capillary endothelium and increase in the thickness and number of layers of the capillary basement membrane; it resembles human "lipoid nephrosis of mixed type," except that no fat is present.—*Authors' summary.*

16302. BENEDICT, JOHANN. Histologische Unterschiede der durch Endokarditis und Lues verunstalteten Aortenklappen. *Virchow's Arch. Path. Anat. u. Physiol.* 281(3): 780-796. 6 fig. 1931.—Study of valves from 17 luetic cases indicates that in valvular syphilis the aortic changes may reach the valves going either up through the sinus of Valsalva (invariably settling in the aortic valve layers and decreasing toward the free edge) or down through the valvular commissure (settling either in the aortic or in the endocardial valvular layers, and

the proliferations of the aortic intima overlapping the free edge of the valve). All these changes are histologically recognizable as inflammatory. In the earliest stages of luetic aortitis there is an enlargement of the aortic valves in all directions, together with hyperplasia of the 2nd layer, which, however, is not distinctive for syphilis. Examination of 28 cases of endocarditis shows that the changes are invariably localized in the endocardial layers of the valves, originate from a thrombus organization, and are therefore most marked at the line of closure. The chief histologic difference between aortic valves deformed by inflammation and by syphilis lies (besides the different localization) in the behavior of the elastic fibers. Only in ascending syphilis does the elastic layer coming down on the valve from the aorta undergo a change—not in descending lues and endocarditis. The endocardial elastica increases in both ascending and descending lues; in endocarditis it is ruptured and destroyed.

16303. **BIANCHINI, M. LEVI.** Virilismo prosopopilare e androfania nella donna alienata. [Masculine beard and voice in insane women.] *Arch. Gen. Neurol., Psichiatr. e Psicoanal.* 11(2): 121-133. 5 pl. 1930.—Observations in 8 cases and hypothesis that virilism of this nature is due, not necessarily to endocrine disturbance, but to the persistence or the reactivation of heterosexual chromosomes present in the embryo.

16304. **BING, ROB., et BERN. WALTHARD.** Quelques aspects anatomo-pathologiques de la myélite herpétique expérimentale. *Schweizer Arch. Neurol. u. Psychiat.* 22 (1): 3-12. 8 fig. 1928.—Guinea pigs inoculated on the sole of the hind foot, after section of the sciatic showed local eruption but no infection of the central nervous system, which always occurred if the sciatic was intact, thus being similar to rabies and tetanus. After the formation of an herpetic vesicle, the virus is propagated along the nerve to the corresponding spinal ganglion; thence to the posterior surface of the lumbo-sacral cord, where inflammatory lesions are characterized by infiltration by lymphocytes and macrophages, and by proliferation of the cells of the sheath of Schwann. Degenerative changes follow, with focal swelling of the axis cylinder. The process in the spinal ganglion is discrete and confined to the surrounding connective tissue. Lesions reach a maximum in the lumbar enlargement and decrease in ascending with infiltration of meninges and perivascular foci of degeneration in the posterior columns, with cell alterations in the posterior horns. The anterior horns are but little affected. Later, there are proliferations of interstitial tissue in both the white and gray substance affected, with loss of myelin in the posterior columns. After the 7th day, the acute lesions regress rapidly, and at the end of a month, the Marchi stain shows very little. It is concluded that herpetic myelitis may result in lesions which are essentially reversible. This explains, in part, the regression of the paralysis in the third period of acute infantile poliomyelitis.—*A. E. Taft.*

16305. **BODECHTEL, GUSTAV.** Zur Frage der Pelizaeus-Merzbacherschen Krankheit. *Zeitschr. Ges. Neurol. u. Psychiatr.* 121(3/4): 487-507. 4 fig. 1929.—Two sisters developed at the age of about 5 a neurological syndrome characterized by gross tremor of the head, ataxia, choreiform movements, speech disturbance, spasticity of the extremities, and progressive dementia. The brain of one of the sisters showed, after her death (due to a lung abscess at the age of 16), an advanced process of demyelinization involving the whole brain, but leaving strip-like perivascular aisles unaffected. The "U"-like fibers of Meynert which are claimed by Merzbacher, to be preserved in Pelizaeus-Merzbacher's disease were considerably involved also. The microscopical picture suggests a slow degeneration and not an aplastic or inflammatory condition. The case stands in between the non-inflammatory form of diffuse sclerosis and Pelizaeus-Merzbacher's disease, and seems to speak for the degenerative ideology of the latter.—*E. Lindemann.*

16306. **BRODRIBB, ARTHUR W., and P. LAZARUS-BARLOW.** A case of aleukaemic leukaemia. *Lancet* 220(5607): 347. 1931.—The differential count showed: polymorphonuclear cells 0; eosinophils, 0; large mononuclears, 6; large lymphocytes, 71; small lymphocytes, 23. Twenty-two nucleated red cells were seen per 100 leucocytes. Stained films from the spleen pulp showed enormous numbers of large lymphocytes. The blood picture (100% mononuclears) with the condition of the glands suggests aleukemic leukemia.

16307. **BRUNNER, HANS.** Der mikroskopische Befund bei einseitigem Fehlen von Mittel- und Innenohr, nebst Bemerkungen zur Ausheilung der otogenen Facialislähmung und zur Myringitis chronica ulcerosa. *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 352-376. 9 fig. 1931.

16308. **CAROSSINI, GIOVANNI.** Su di un raro caso di neuroma plessiforme del bicipite brachiale. [A rare case of plexiform neuroma of the brachial biceps.] *Arch. Ital. Chir.* 23(2): 172-184. 3 fig. 1929.—The author reviews the various theories on the morphologic and histogenetic interpretation of tumors arising from nerves, concluding that there may be: neuroma myelinicum; neuroma amyelinicum; neuroblastic or cellular neuroma. He then reports a case, from a complete gross and microscopic study of which he concludes: that although trauma cannot be said to be the cause of the tumor, it may certainly have an untoward influence on its course; that the nerves of the brachial plexus are the most frequent sites of tumors (as in this case); that the diagnosis must consider the acinous feel on palpation, the spontaneous pain and provoked tenderness, and the slow course.—*A. M. Sala.*

16309. **CRILE, GEORGE W., MARIA TELKES, and AMY F. ROWLAND.** The nature of living cells with special reference to the nature of cancer cells and of fatty degeneration. *Arch. Surg.* 23(4): 703-714. 8 fig. 1931.

16310. **DAVISON, CHARLES.** Subacute combined degeneration of the cord. Changes following liver therapy; a histopathologic study. *Arch. Neurol. and Psychiatr.* 26(6): 1195-1219. 14 fig. 1931.—Of 17 cases of pernicious anemia complicated by subacute combined degeneration, 7 had undergone liver therapy. All the treated but none of the untreated cases showed glial proliferation at autopsy. The myelin sheaths and axis cylinders were not influenced by the liver therapy.

16311. **ERDHEIM, J.** Über Wirbelsäulenveränderungen bei Akromegalie. *Virchow's Arch. Path. Anat. u. Physiol.* 281(1): 197-296. 28 fig. 1931.—This is a continuation of a monograph on acromegalic changes in the cartilage of ribs and joints. Changes take place both in the bony structure and in the intervertebral cartilages. These can be seen with the x-ray, as well as by gross and microscopical examinations. In the bone, there are alterations in the marrow, bone tissue and periosteum. The greatest amount of new growth arises from the periosteum, and a distinct line of demarcation can be seen between this and the bone proper. This is the principal distinguishing difference between acromegalic processes and spondylitis deformans. The chief function of the intervertebral cartilages is their cushion-effect; this is destroyed by loss of their turgor in degenerative processes. Calcification of cartilage always depends upon the relative pressure between it and the adjacent bone. Where there is increased stress, a proportionate amount of Ca flows from bone to cartilage, and in the opposite direction when the condition is reversed. The microscopic picture of the cartilage changes in acromegaly is chiefly granular albuminoid degeneration with vacuolization. This is a chemical change due to the solution of a fraction of the chondroitin sulphuric acid-albumin combination. There are also non-visible changes of fermentative origin. Cartilage cells persist for some time after other processes have reached a more extreme degree. At a certain point the center of the lesion may undergo mucoid degeneration. Repair takes place by growth of new cartilage cells where there are breaks or cavities in the tissue; also by fibrous replacement, and

by new bone growth. The etiology of acromegaly is unknown. The process is due not to injury, but to hyperpituitarism, the cause of which has not been determined. It is also unknown what causes the process to terminate. There is a great deal of detail in this article. A short bibliography is included.—*A. E Taft.*

16312. **FEEMSTER, ROY F. Spontaneous rupture of the heart.** *Amer. Jour. Path.* 7(3): 223-228. 9 fig. 1931.—This case bears out the claim made by Beresford and Earl that rupture usually occurs in an infarcted area, frequently the result of coronary disease and precipitated by coronary thrombosis or embolism.—*From author's summary.*

16313. **FELDMANN, GRIGORY. Die apikale Paradentitis im Lichte des Experimentes. [Experimental considerations of apical paradentitis.]** 227p. 65 fig. Hermann Meusser: Berlin, 1931. Pr. 18.80 M.—Apical paradentitis is discussed in 14 chapters. After a critical review of problems concerning the treatment of teeth with inflamed or putrid pulp, the author gives a brief summary of anatomy, histology and physiology of the paradentium. The effect of arsenic acid and cobalt on the paradentium and the alterations of this tissue after extirpation of the destroyed and not destroyed pulp are treated. Comparative clinical and pathohistological study over devitalization and anesthesia of the pulp show that both methods are imperfect. The material shows that there is no difference between the periapical alterations of teeth with good or bad fillings. The histological alterations of the paradental tissue after treatment and filling with formalin and tricresolformalin show the latter is better. Howe's silver method and other metallic fillings are not suitable for treatment of the nerve-duct, because they are resorbed. The relations of apical paradentitis and oral sepsis are treated, followed by a comparative discussion of the effects of the different drugs on the paradentium. The experiments were performed on 85 dogs.—*M. Silberberg.*

16314. **FERGUSON, JOHN A. Erythroblastosis with jaundice and edema in the newly born.** *Amer. Jour. Path.* 7(3): 277-298. 10 fig. 1931.—In the 6 cases reported, the outstanding feature was abnormal extramedullary hematopoiesis in full term non-syphilitic infants, all dead at birth or soon after. In each there was a persistence of the fetal mode and site of hematopoiesis without a corresponding retardation in general embryological development. Of 3 cases showing marked jaundice at birth, in 1 bile stasis was present in the liver, perhaps due to excessive hemolysis of imperfectly differentiated erythrocytes loading the liver cells with bile pigment more rapidly than it could be taken care of by the bile-excreting apparatus; 1 case was complicated by an infection, apparently not related to abnormal hematopoietic activity or to the jaundice. Marked edema (hydrops congenitus) was present at birth in 2 cases. One case showed neither jaundice nor edema. All cases showed a marked enlargement of the spleen and liver.—*From author's summary.*

16315. **FOIX, CHARLES et I. NICOLESCO. Anatomie cérébrale. Les noyaux gris centraux et la région mesencéphalo-sous-optique suivi d'un appendice sur l'anatomie pathologique de la maladie de Parkinson.** 582p. 356 drawings, 6 col. pl. Masson et Cie: Paris, 1926. Pr. 100 fr.—Whatever their embryonic origin and their situation in the organization of the central nervous system, the nuclei of the corpora striata, hypothalamus, the tuber cinereum, and of the mesencephalon, together with their connections make a whole system not only topographically but also anatomo-physiologically. In this monograph the authors have added to classical descriptions the recently acquired facts, with the results of their own studies on these formations. In part I there is a brief description of the elementary notions of anatomy necessary for the understanding of the following part. An alphabetic index gives precise definitions of the nuclei and the connecting bundles, followed by a brief abstract of embryology. Part II is a topographic study of series of cuts in the 3 planes: verticofrontal, horizontal, and sagittal. This study contains 2 parts: Part 1 is given to the study of the cuts colored by the myelinic methods and provides the necessary elements for the topographic representation of the divers nervous bundles. Part 2 is devoted to the study of cuts in the same planes, colored by cellular methods. This chapter brings elements which are useful for the comprehension of the whole complex disposition of the many cellular groups of the region. Part II of the book aims to give the reader the necessary notions for the study of Part III and to present model cuts from which the anatomical pathologist can study and recognize his own cuts. Part III of the monograph contains detailed study of the striate bodies, the thalamus, Luys' body, the zona incerta, the nuclei of Forel's field, the internal capsule, the innominate substance of Reichert, the white formations of the sublenticular region, the amigdaloid nucleus, the infundibulo-tuberian region, the corpus mamillaris, the red nucleus of Stilling, the black substance of Soemmering and the commissurae of the brain stem. This study unites in the synthesized descriptions everything known about the formations described: cytoarchitectonics, myeloarchitectonics, connections, comparative anatomy, embryology, myelogenesis and blood vessels. The plates and drawings which illustrate the text are nearly all made from original preparations. The final part of the monograph is dedicated to the histo-pathologic study of Parkinson's disease. To sum up, Parkinson's disease means an early senescence of the nervous centers, which begins in the extrapyramidal and vegetative formations and which is continued by diffuse alterative processes expanding progressively in other endoneuraxial formations. The principal lesions occupy the globus pallidus and the locus niger; the predominating alterations involve the nerve cells which present lesions of the abiotrophic type. Parkinson's disease with the diffuse alterations of the senile type which accompany it, appears as an abnormal localization of the process of cerebral senile decay, or as a process resembling senility brought about by an unknown adjacent or determinative factor, although it is definitely known that this factor is often infectious. So considered, Parkinson's disease loses its individuality. Perhaps there are no absolute limits between Parkinson's disease and the parkinsonian syndromes found in infectious diseases as, e.g., epidemic encephalitis. There are no absolute limits between Parkinson's disease and the pseudo-bulbar parkinsonism of the aged. The anatomic pathological definition of Parkinson's disease is above all a question of localization of the lesions. Therefore it is thought that some symptoms observed sometimes in the aged, as rigidity or isolated or limited trembling, which manifest themselves without Parkinsonian syndrome can be attributed to their true nature which is Parkinsonian.—*C. Foix.*

16316. **HAACK, KARL, und GERHARD KREYENBERG. Vergleichende kapillarmikroskopische Untersuchungen an früher sogenannten "puellae publicae" und dem Durchschnittsmaterial einer dermatologischvenerologischen Abteilung.** *Dermatol. Zeitschr.* 59(2): 95-103. 4 fig. 1930.—The authors undertook to study in 100 prostitutes the theory that frequent infantile capillary development in such classes denotes a psychic inferiority. They found 22% of capillaries of immature forms, which is a percentage no higher than the general average of patients in the venereologic division. Of 21 physically and mentally sound nurses and attendants, 10% presented immature capillary forms. The authors conclude that, while capillary microscopy may furnish instructive clues, it is not sufficient in itself to establish the fact of feeble-mindedness.—*From authors' conclusions (by Z. Cooper).*

16317. **HALKIN. Note sur les réactions du stroma conjonctif dans les épithéliomas cutanés.** *Bull. Acad. Roy. Méd. Belgique* 10(7): 385-391. 4 fig. 1930.—Study of excised specimens (on the basis of Bierich's theory of exposed forces in the production of cancer) has convinced the author that the production of elastic fibers is

the most constant defensive reaction in cutaneous epitheliomata. This reaction is particularly striking and effective in localized slowly developing and non-metastasizing basal cell epitheliomata, but gives way before epithelial invasion. The same defensive reaction occurs in spinal cell epitheliomata, but is there rapidly broken down. In both forms it appears as an intense defensive effort in the hedge of papillae of healthy skin, where it appears before any cellular infiltration.

16318. HALL, ERNEST M., and EATON M. MacKAY. Experimental hepatic pigmentation and cirrhosis. I. Does copper poisoning produce pigmentation and cirrhosis of the liver? II. The effect of heavy carrot-feeding on the rabbit's liver. *Amer. Jour. Path.* 7(4): 327-342, 343-350. 9 fig. 1931.—A litter-mate control of the same sex was fed a special control diet for each rabbit that received Cu. A diet containing 2 mgm. of normal Cu acetate in each gm. of food (alfalfa and barley) was fed to 21 rabbits for 21-105 days. Of the Cu-fed animals 17 showed pigmentation of the liver, mostly as hemofuscin stored in Kupffer giant cells; 9 showed cirrhosis of the liver; 5 which failed to show cirrhosis showed varying degrees of liver cell necrosis. Na acetate, substituted for the Cu salt in the diet of 3 rabbits produced no changes in the livers.—*From authors' summary.*—II. A high percentage of carrots was fed for 32-50 days to 22 rabbits (with litter-mate controls) divided into 3 groups on 3 different diets; 3 developed Kupffer giant cells containing a moderate amount of hemofuscin; 1 developed a definite early cirrhosis; 2 others showed slight connective tissue proliferation in the livers. Many rabbits showed clear, vacuolated cytoplasm in the liver cells probably due to excess glycogen storage. Other changes included parenchymatous degeneration, fatty infiltration and early nuclear degenerative changes. These conditions may be dependent upon diet-deficiency due to the almost exclusive diet of carrots.

16319. HAMPERL, HERWIG. Über erworbene Heterotopien ortsfremden Epithels im Magen-Darmtrakt. *Beitr. Path. Anat. u. Allg. Path.* 80(2): 307-335. 10 fig. 1928.—The author reviews a number of cases of epithelial heterotopy in the digestive tract of man, citing various instances of ectopic stratified, ciliated, intestinal and pseudopyloric or mucoid epithelia. These cases of acquired heterotopy are frequently associated with definite pathological states—carcinoma, tuberculosis, etc.—or are found after operative interference, such as anus praeternaturalis and gastroenterostomy. The abnormal or altered physico-chemical conditions to which the tissues are exposed may be an important factor in the abnormal differentiations encountered. There is a discussion of the relation of epithelial heterotopy to physiological regeneration, restorative regeneration, dedifferentiation followed by abnormal differentiation, pluripotentiality and the relative degree of differentiation of the epithelia of the various levels of the digestive tract.—*A. B. Dawson.*

16320. HINTON, J. WILLIAM. Normal thyroid in relation to the classification of goiters. Histologic studies. *Arch. Surg.* 23(2): 191-200. 11 fig. 1931.—Since in 80 cases of accidental death (0-89 yrs), the author was unable to find a relatively constant picture of the thyroid for different ages, it was difficult to conclude what was normal. In 16 cases due to acute and 11 due to chronic diseases, the sections showed no definite changes. Conflict between clinical and pathologic features is reported in 4 cases of various thyroid disturbances. The author suggests that the previously so-called various types of goiter may be merely stages of one continuous disease.

16321. HUEPER, W. C., G. E. WOODWARD, and E. G. FRY. Interrelations between histologic structure and blood chemical findings in cancer. *Amer. Jour. Cancer* 15(4): 2666-2674. 1931.—The malignancy indices and the blood pH of 34 cases of carcinoma were correlated and a preponderance of histologically highly malignant tumors was found in patients with an alkalosis, while tumors of histologically low malignancy predominated in patients with a normal blood pH. The alkalosis of the blood in cancer patients varies not only with the extent of the disease, but also with the degree of malignancy and maturity of the tumor. The degree of cellular irregularity of cancerous tissue is increased in patients with an alkaline pH of the blood as compared with patients with a blood pH of normal range. In about ⅓ of the cancer patients with a hyperglycemia (present in 78.3% of the cases) a high number of mitoses was found, while this phenomenon was absent in cancers with normal blood sugar.—*Authors' summary.*

16322. HÜNERMANN, TH. Über histopathologische Untersuchungen an der Luftröhrenschleimhaut unter besonderer Berüchsichtigung toxischer und infektiöser Gewebsschädigungen. *Beitr. Anat. Ohres, Nase u. Halses* 29(1/2): 79-99. 4 fig. 1931.—In 9 cases of grippe, the tracheal mucosa showed symptoms of diffuse inflammation microscopically, but the extensive toxico-degenerative signs in the mucous glands described by Wätjen for the grippe epidemic, 1918/19, were absent. Apparently these symptoms depend on the character of the epidemic. Both mucosa and glands showed distinct signs of toxic lesions in 3 cases of diphtheria. In whooping cough, too, a toxic effect was seen in the relatively slight inflammatory defense reaction of the tissue. For comparison, tracheas which had undergone only postmortem changes without any previous inflammatory process were examined. In one case, 9 yrs. after mustard gas poisoning, the epithelium of larynx and of trachea showed marked metaplastic alteration; finally a carcinoma formed. In 2 subjects who died of pulmonary tuberculosis the trachea remained free of tuberculosis; on the other hand, in a case of tuberculous meningitis in which the lungs were free of active tuberculosis there was a caseated tubercle in one gland lobule. It is assumed that the infection of the glands resulted from the excretory duct.—*From author's summary (transl.).*

16323. IFF, W. Über angeborene Verkalkungen, besonders der Arterien. *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 377-395. 1 fig. 1931.—In a new-born ♂ infant, dying a few minutes after birth, multiple calcification was found especially in the inner layers of the media, in part also in the intima and in the adventitia of the arteries, particularly the large and medium sized, more seldom in the smaller arteries. Calcifications also occurred in the interlobular connective tissue of the thyroid, in the glomerular capsules and the glomeruli of the kidneys, also in the interstitial connective tissue, in the retroperitoneal fatty tissue, in the cerebral pia mater, in the umbilical vein, and in the placenta. The Ca was deposited in the chromotropic fundamental substance of the arteries and other organs. A marked increase of chromotropic ground substance over the normal was present in the superior femoral vein, with no indication of disorganization. The calcification is attributed to incomplete development of the fundamental substance, congenital or produced by the hydramnion.—*Author's summary (transl.).*

16324. ITCHIKAWA [ICHIKAWA], K., T. YAMAHO, and J. FUJIMORI. On the standard weight of the spleen, the liver and the kidney of the horse, and on the variation of weight of these organs in the case of the different diseases. [In Japanese.] *Jour. Soc. Agric. and Forestry Sapporo, Japan* 20(91): 149-172. 1929.

16325. JACOBSEN, VICTOR C., and KIYOSHI HOSOI. The morphologic changes in animal tissues due to heating by an ultrahigh frequency oscillator. *Arch. Path.* 11(5): 744-759. 2 fig. 1931.—Exposure of 23 dogs, 27 adult white rats, and 3 guinea pigs in the electrostatic field of a high frequency oscillator produced marked hyperthermia, the amount of temp. increase being controllable by altering either the voltage or the distance between the plate electrodes. The morphologic changes were congestion of the organs, peripheral hyperemia, cloudy swelling, fatty degeneration, dehydration, glycogen depletion, focal hemorrhages, especially in the gastro-intestinal tract, epithelial hyperplasia in the parenchymatous organs and stimulation of the bonemarrow.

Following prolonged periods of heating, degenerative lesions occurred in the ♂ germinal epithelium. Morphologically the alterations differed but little from the effects of fever produced by various other methods.

16326. **JORSTAD, LOUIS H., and CLINTON W. LANE. Gross and microscopic changes in the skin produced by x-rays and by lipoid solvents.** *Arch. Dermatol. and Syphilol.* 19(6): 954-967. 2 fig. 1929.—An area of skin 1 cm. in diameter on the back of adult white rats was painted with different lipoid solvents or given varying dosages of x-ray. The gross and microscopical changes resulting were studied. Active precancerous lesions were produced by the repeated painting with a diluted tar preparation. The same type of lesions was produced by a single exposure of unfiltered x-ray or by combining the 2 procedures. Relatively small doses of x-ray produced the most marked changes, in that larger doses cause a necrosis of the epidermis and glandular structures as well. In the more extensive burns the derm on the edges shows the hyperplasia of skin and glandular structures as was seen throughout the lesions in the less extensive burn. Observation of these histological changes at different intervals led the authors to conclude that coal tar and allied substances, such as mazola oil, paraffin oil and neat's foot oil, and x-ray, act similarly in inducing a malignant condition. They act as lipoid solvents. The differences in the degree of change produced by each may be attributed to the different nature or "drasticity" of the lipoid solvent used.—*L. H. Jorstad and C. W. Lane.*

16327. **KEY, J. ALBERT. Experimental arthritis: The changes in joints produced by creating defects in the articular cartilage.** *Jour. Bone and Joint Surg.* 13(4): 725-739. 7 fig. 1931.—In experiments on 20 rabbits many of the changes associated with hypertrophic arthritis were produced by creating a defect in the cartilage.

16328. **KODAMA, MAKOTO, und KENSABURO TAKAHASHI. Zur histodiagnostischen Bedeutung der Gehirnveränderung beim fleckfieberinfizierten Meerschweinchen. II. Experimentelle Studien über das Fleckfieber.** *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 32-36. 1931.—In febrile guinea pigs with typhus infected with virus from 77th passage, the brains [133 examined, 155 rabbits inoculated] showed the so-called typhus nodules, most frequently in the middle portion of the cerebral cortex, 3-14 days after appearance of fever. In unquestionable typhus infection of guinea pigs, the 4 diagnostic signs (fever, decrease in body weight, transitional monocytosis, and nodular foci in the brain) were always present.—*Author's summary (transl.).*

16329. **KÖHLER, RUTH. Beiträge zur Kenntnis der thyreosuprarenalen Erkrankung (M. B. Schmidt).** *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 466-482. 1931.—In 2 cases clinically recognized as Addison's disease, necropsy showed high grade atrophy of the adrenals. The thyroid in one also was atrophic, in the other apparently normal, suggesting that the thyroid atrophy frequently seen in Addison's disease is due to constitutional weakness of the organ. This conclusion was supported experimentally. In 20 guinea pigs 1 adrenal was removed, and in 11 of these the other adrenal was later crushed, without effect on the thyroid. Thyroxin and insulin injected each into 6 guinea pigs had no effect on the adrenals.

16330. **KÖNO, MICHIO. Über die Blutmonozytose bei fleckfieberinfizierten Meerschweinchen. III. Experimentelle Studien über das Fleckfieber.** *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 37-39. 1931.—In 9 guinea pigs not infected with typhus no significant leucocytic changes appeared; in 15 with unquestioned infection an intra-infection neutrophil leucocytosis and a postinfection lymphocytosis were often observed and, without exception, a more or less evident transitional monocytosis.

16331. **KUFS, H. Die histochemischen Grundlagen der Darstellung der Spirochaete pallida im Gefrierschnitt nach Kanzler und eine brauchbare Modifikation dieser Methode.** *Zeitschr. Ges. Neurol. u. Psychiat.* 118(4): 516-525. 2 fig. 1929.—The author discusses the chemical reasons for the success of Kanzler's staining method of staining spirochaetes in tissue. He places special stress on the combination between uranium, silver and spirochaetes in the reduction process brought about by formalin solutions. He also discusses the relative value of $Ag(NH_3)_2NO_3$ solution, $Ag(NH_3)_2OH$ and NH_3AgCO_3 in these staining methods. In his modification he uses the first of these because it forms the most stabile compound, reacts least with light, is slowly reduced and combines most powerfully with the tissue. Frozen sections are placed in bromium ammonium formalin solution for 10 min., in pyridin for 10 min., and in ammonium nitrate 5% solution 10 min., between each change being washed thoroughly with distilled water. They are brought into 1½% silver nitrate solution and stained for 10-20 min. in an oven at 50°C. The sections are washed quickly in water and reduced by the modification of Kanzler's method (.5 part soda, 20 parts distilled water, 10% formalin solution) or after Kuf's method. (Silver ammonium nitrate solution is prepared by adding ammonium hydroxide drop by drop to 5 cc. of 10% $AgNO_3$ until a precipitate forms and redissolves, and 50% formalin solution.) Each section must be individually reduced.—*C. J. Bucher.*

16332. **LADAME, CHARLES, et FERDINAND MOREL. Contribution à la topographie des lésions histologiques du cerveau sénile.** *Schweizer Arch. Neurol. u. Psychiat.* 27(2): 301-310. 8 fig. 1931.—The method consisted in rigorous comparison of the senile plaques, the neuroglia, the ganglion cells and the blood vessels of symmetrical cortical areas. In both hemispheres marked similarity in number, morphology and cortical distribution of the senile plaques was noted. No constant relationship was noted between the senile plaques and the degree of cerebral atrophy. The least symmetrically arranged of the glia cells were the macroglia with best developed fibers which give these astrocytes a strikingly cicatricial character. The astrocytes attached to blood vessels were much more symmetrically arranged, but the contrary was true of the microglia. Ganglion cells of the Alzheimer type were present in circumscribed areas of the cortex which were, in general, symmetrical. There is striking symmetry of the vascular changes. Whereas vascular sclerosis (la fibrose artério-capillaire) is too diffusely distributed for the comparison of its extent in symmetrical areas, foci of softening (l'état lacunaire et l'état criblé) have a symmetrical distribution. The same may be said for the arteries radiating from the white matter.—*J. R. Cash.*

16333. **LAMBERTINI, GASTONE, e PIETRO MAINOLDI. Ricerche sperimentali intorno agli effetti delle radiazioni Röntgen sulla neurorete del Donaggio nei mammiferi neonati. [Some of the effects of x-rays on the neuroreticulum of Donaggio in new-born mammals.]** [Summaries in French, English, and German.] *Riv. Radiol. e Fis. Med.* 1(4): (3-17). 9 col. fig. 1929.—The neuroreticulum of Donaggio in the spinal nerve cells of new-born but not of adult dogs, is extremely sensitive to x-rays. The lesions which appeared in these researches are characterized by woolliness of the fibrils, and by breaking up of the neuroreticulum with the appearance of granulosity and of large vacuoles in its midst. The lysis and the consequent disappearance of the neuroreticulum is made evident in small groups of elements variously distributed. The vulnerability to x-rays of Donaggio's neuroreticulum in adult mammals as reported by Mondini, has been observed only when refrigeration was added to the action of the x-rays. The present studies indicate the vulnerability of the neuroreticulum under the isolated influence of the x-rays: evidently this demonstration depends on the special conditions of the experiment, that is, the extreme youth of the animals exposed to the irradiation. While the lysis of the neuroreticulum in adult animals occurs only through the stage of conglutination of the neuroreticulum itself and by means of the combined use of the x-rays and refrigeration, in these present studies the use of the x-rays led directly to the lysis of the neuroreticulum without pass-

ing through the phase of conglutination.—*Author's summary.*

16334. **LAZZARINI, LANFRANCO.** Osservazioni sul cancro gelatinoso della mammella. [Gelatinous mammary cancer.] *Arch. Ital. Anat. e Istol. Patol.* 1(3): 367-382. 6 fig. 1930.—On the basis of 3 cases of so-called gelatinous cancer, 2 of tubular and 1 of cysto-adenomatous type, the author rejects the theory of origin from mucous secretion and concludes that the tissue represents the total or partial gelatinous metamorphosis of a pre-existing tumor.

16335. **LOTMAR, F.** Histopathologische Befunde in Gehirnen von kongenitalem Myxödem (Thyreoaplasie). *Zeitschr. Ges. Neurol. u. Psychiatr.* 119(4): 491-513. 10 fig. 1929.—The author reports 2 cases of congenital thyreoaplasia and discusses the histopathologic findings. In case 1, he found a reduction in the number of cells in the second and third layers of the frontal and parietal lobes; in case 2 the main changes referred to a disturbance in the architecture of the cerebellum. In both cases, a developmental disturbance must be assumed. Jakob found similar changes in mongolism. Besides this reduction in cell content an edema of the upper layers of the frontal and parietal lobes is common to the thyreoaplasias and the mongoloid conditions. In addition, there are involutional changes in the brain, exemplified by a marked fat content of the ganglion cells and by regressive transformation of the glia. The condition must be considered as a chronic toxic metabolic disturbance. Experimental evidence of thyroidectomized animals tends to support this view. Calcifications have been reported in the pallidum. Such changes must also be interpreted as involutional processes. The fact that it is mainly the cortex, both of the cerebrum and of the cerebellum, that is involved merely emphasizes the greater vulnerability of the neopallium, as contrasted with the greater resistance of the older brain structures. —*A. A. Low.*

16336. **McCARTHY, LEE.** Histopathology of skin diseases. 513p. 54 col. pl., 197 halftones. C. V. Mosby Co.: St. Louis, Missouri, 1931. Pr. $25.00.

16337. **MacCARTHY, WM. CARPENTER.** The malignant cell. *Jour. Cancer Res.* 13(2): 167-172. 3 fig. 1929. —All malignant cells arise from regenerative cells of normal tissue and in the opinion of the author even single malignant cells can be recognized by certain characteristics in fresh unfixed and unstained material, using an oil immersion lens.—*G. L. Rohdenburg.*

16338. **MACCHIARULO, O., und J. TANNENBERG.** Über oxyphile Zellen. *Zeitschr. Immunitätsforsch.* 63 (1/2): 56-66. 1 pl. 1929.—The work is based on the question whether special cells of the blood or of the connective tissue have the ability to form a series of other types of cells such as are seen in inflammatory reactions. In 8 experiments made by injecting a suspension of a 24-hr. culture of *Staphylococcus aureus* into the peritoneal cavity, pleural cavity, subcutaneous tissue and striated muscle of guinea pigs, the animals were killed at intervals from immediately after injection to 6 hrs. Histologic studies of smears of the exudates and sections of adjacent tissue were made. The oxyphil cells which di Renzo believed to be transition forms between endothelial cells and leucocytes were considered to be merely degenerating cells, although the authors' findings agreed in general with di Renzo's. They call attention to the necessity for differentiating between the oxyphil cell whose cytoplasm stains solid red with eosin and the true eosinophil, whose cytoplasm contains pink staining granules.—*H. A. Davenport.*

16339. **MANICATIDE, M., et I. NICOLAU.** Seize cas de nouveau-nés vaccinés par le B.C.G. et morts de maladies intercurrentes. Etude histopathologique. [Histopathological study of 16 cases of new-born, vaccinated with B.C.G., who died of intercurrent diseases.] *Arch. Roumaines Path. Exp. et Microbiol.* 2(1): 81-104. 4 pl. 1929.

16340. **MORITZ, ALAN RICHARDS.** Interacinar epithelium of the thyroid gland. *Amer. Jour. Path.* 7(1): 37-46. 2 pl., 3 fig. 1931.—Histologic studies (no. of subjects not stated) indicate that in normal thyroids of fetuses, children and adults, in pathological glands the seat of hypertrophy and hyperplasia, in nodular goiter, and in adenomas of the thyroid, the mechanics of hyperplasia are essentially similar. New follicles are formed by intra- and extra-follicular proliferation of epithelium and the secondary follicles may lose their parent connection and become isolated units. In the scattered foci of hyperplasia in normal thyroid glands, as well as in glands that are the seat of pathological hypertrophy and hyperplasia, labyrinthine intercommunication of acini exists and is probably limited to the connection of primary with secondary acini. Solid masses of undifferentiated interfollicular epithelium are found in both normal and pathological glands, but such masses are readily accounted for as detached extra-follicular buds. Evidence contrary to certain observations by Rienhoff concerning the mechanics of hyperplasia in the thyroid gland is presented.

16341. **NICHOLSON, G. W.** An embryonic tumour of the kidney in a foetus. *Jour. Path. and Bact.* 34(6): 711-730. 2 pl. 1931.—Both parts of the developing kidney are represented in the tumor. Union between its ureteric and metanephrogenic parts has failed. Differentiation of its tissues is physiological in type, though defective in varying degree: e.g., the collecting tubules have retained their functions as "organizers" of Spemann; differentiation of the Malpighian corpuscles corresponds with that of those of the kidneys. The tumor represents the present stage of development of a kidney anlage after abnormal stimulation. It is a malformation and has acquired no new, "un-biological" characters.—*G. W. Nicholson.*

16342. **PUCCINELLI, ENRICO.** Su di un caso di cancro primitivo del fegato con metastasi multiple ossee in attiva secrezione biliare. [A primary hepatic carcinoma with multiple bone metastases actively secreting bile.] *Arch. Ital. Anat. e Istol. Patol.* 1(5): 781-795. 2 fig. 1930.—The primary tumor and all the metastases (all the latter located in the skeletal system) had an identical structure, being composed of cells similar to those of the liver, and all contained biliary pigment.

16343. **REITANO, RICCARDO.** Le alterazioni del sistema nervoso centrale e periferico nelle avitaminosi sperimentali. Ricerche su colombi e cavie e considerazioni patogenetiche. [Changes in the central and peripheral nervous system in experimental avitaminosis of pigeons and guinea pigs.] *Arch. Ital. Anat. e Istol. Patol.* 2(2): 239-292. 8 pl. (2 col.) 1931.—In the cerebrum in 16 pigeons with beriberi induced by a diet of polished rice, the only noteworthy phenomenon was tigrolysis, which the author interprets as a transitory and reversible disturbance in the nerve cell. No fatty degeneration or glial reaction was observed. Results of examination of the spinal cord and other portions of the nervous system were negative. Following Di Mattei, the author found that a diet of polished rice mixed with sunflower seeds produced an avitaminosis picture limited to paralysis of the limbs, a phenomenon always reversible by addition of brewer's yeast to the diet. The author concludes that the pathologic anatomy of beriberi in pigeons is essentially that characteristic of inanition.

16344. **REUTER, MAURICE J.** Histopathology of the skin in myxedema. *Arch. Dermatol. and Syphilol.* 24 (1): 55-71. 6 fig. 1931.—Specimens from 12 myxedema patients showed fairly uniform hyperkeratosis of the epidermis, with hyperkeratotic plugging of the hair follicles and sweat ducts; irregular, scattered atrophy of the epidermis, with degenerative changes in the epidermal cells; pronounced edematous changes in the corium, and in consequence a spreading apart of the collagen and elastic fibers associated with mild degenerative changes; a sparse cellular infiltrate about the vessels in the upper part of the cutis, and in a few cases about the hair follicles and sweat glands; and the constant presence of a mucinous staining material in considerable quantities. The characteristic appearance of patients is, in all

probability, the result of edema and the presence of the excess of mucin in the corium. In 10 cases in which the basal metabolic rates were low but myxedema not present, the cutaneous histologic picture was similar to that in myxedema, except for the absence of marked edematous changes. Mucin is probably a normal constituent of the skin.

16345. **RIX, ERICH. Die Melanose der Kälber.** *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 396-411. 4 fig. 1931.—In 2 calves with high grade melanosis, the greater part of the pigment was deposited in mesenchymal cells—apparently tissue histocytes and adventitial cells. A heavy deposit of pigment in the mucosa of the soft palate and the nose occurred in the epithelial cover cells and epithelial cells of the excretory ducts—a finding contradictory to the present conception that pigmentation is confined to derivatives of the mesoderm, and to Jäger's view that pigment is deposited only in the cover cells of the lymph vessels and (in the liver) in the stellate cells. The distribution of pigment corresponds to Weidenreich's scheme, which confines the deposit to 4 (or 2) layers.—*Author's summary (transl.).*

16346. **SCAGLIA, GIUSEPPE. Sulla sarcosporidiosi cardiaca con speciale riguardo alla patologia del fascio di His.** [Cardiac sarcosporidiosis, with special reference to the pathology of the bundle of His.] *Arch. Ital. Anat. e Istol. Patol.* 1(2): 156-182. 1 pl. (col.), 4 fig. 1930.—In the hearts of about 100 cattle and many sheep, all apparently in good general condition, taken at random from a slaughter house, sarcocysts were "constantly" found in the myocardium and particularly in the bundle of His, the nerves however being spared. To explain the fact that the animals had apparently suffered no injury from this heavy myocardial infestation, the theory is advanced that the function of the bundle of His is exercised through the nerves. In the reported human cases of fatal cardiac paralysis, the continuity of the entire bundle of His was apparently interrupted.

16347. **SCHAUMANN, J. Localisation dans la moelle des os au cours du lupus pernio type Hutchinson. Contribution à l'étude de la lymphogranulomatose metascrofuleuse et du lupus érythémateux.** [Localization in the bone marrow during pernicious lupus, type Hutchinson.] *Haematologica 1. Arch.* 11(6): 449-464. 6 fig. 1930.—The case was characterized by tumefaction of the nose and ears and by digital deformation. Cutaneous and marrow lesions were identical with those found in erythematous lupus. To distinguish the case from benign lymphogranuloma the author characterizes it with the term metascrofulous lymphogranulomatosis.—*N. A. Michels.*

16348. **SEULBERGER, P., W. SCHMIDT, und F. KRÖNING. Röntgenbiologische Untersuchungen an Carcinomen. I. Mitteilung. Cytologische Studien an oberflächlichen und tiefgreifenden menschlichen Carcinomen.** *Strahlentherapie* 31(3): 467-494. 37 fig. 1929.—A cytological examination of 5 superficial and 4 deep carcinomata showed that the number and quality of the mitoses varied widely, even before radiation. After radiation a quantitative as well as qualitative change in the karyokinesis of each tumor was observed, and the time of this change was variable. The resting cells of the tumor also showed changes. Many of the cells, especially those of deep seated tumors, showed processes of dissolution after the radiation which, perhaps, indicated a fermentative change. Increased round cell infiltration and proliferation of connective tissue in and around the tumors was probably a reaction of the organism, especially noticeable after radiation.—*O. Glasser.*

16349. **SJÖVALL, ALF, und HELGE SJÖVALL. Experimentelle Studien über die Sekundärknötchen in den Kniekehllenlymphknoten des Kaninchens bei Bacillus pyocyaneus-Infektion.** *Virchow's Arch. Path. Anat. u. Physiol.* 278(2): 258-283. 37 fig. 1930.—To ascertain whether or not formation of new secondary nodules is produced in the lymph nodes of the popliteal space of rabbits after an injection of a virulent culture of *Bacillus pyocyaneus* in the region of the lymph vessels, an accurate method for determining the various tissue components of lymph nodes was worked out, by which the lymph nodes of 11 normal and 22 experimental animals were studied. From 5 to 7 days after the injection the infected rabbits showed a significant formation of new secondary lymph nodes (s.l.n.), which after approximately 10-20 days reached their maximum, surpassing the lymph nodes of the other side as well as those of the normal animals by hundreds. After a month the s.l.n. subsided. These facts seem to support Hellman's theory that s.l.n. represent reaction centers against the bacteria, etc. In these experiments the swelling of the lymphatic tissues was noted. It was shown that under normal conditions the difference in weight of the popliteal lymph nodes of 49 animals amounted at most to 1 cgm. The condition of the experimental animals was quite different. In the first days of the experiment the lymph nodes of the infected side were very much swollen, and surpassed those of the other side by many cgm. These decreased during the course of the experiment. The swelling did not take place at the same time as the formation of new s.l.n., for the swelling had already subsided when the new formations reached their height—after 10-20 days. Generally speaking, the average size of the s.l.n. was much larger in the infected side; however, in this particular, no definite reaction can be pointed out. Also nothing specific can be said concerning the relative amounts of cortex and medulla. Accurate microscopical examinations have shown that in these inoculation experiments no demonstrable general reaction was present in the lymphatic system. The reaction seemed to be much more strongly localized in the lymph nodes of the infected side. Only here may the various types of changes be seen.—*Authors' summary (transl. by H. Jackson, Jr.).*

16350. **STEWART, FRED W. Primary liposarcoma of bone.** *Amer. Jour. Path.* 7(2): 87-93. 3 pl. 1931.—A probable diagnosis of liposarcoma in 3 cases was based on the resemblance of the tumor cells to fat cells, the presence of large fat droplets in 1 case, the general resemblance to fat cells in another although no specific fat stains were available, and the xanthomatous droplets in the second case; the peculiar clinical course, namely, a suggestion at least of multiplicity of bone lesions in all 3 instances which recalls the behavior of certain of the liposarcomas observed in the soft parts; lack of evidence of primary epithelial origin; and an appearance inconsistent with primary bone tumors of known types. All 3 tumors were either multiple in bone or else showed a marked tendency to metastasize to other bones. Of the 2 cases treated by irradiation both proved radiosensitive, a behavior inconsistent with any primary osteogenic bone tumor of comparable structure, or with a metastatic adenocarcinoma, but not inconsistent with certain liposarcomas observed in the soft tissues.

16351. **STRUWE, FRIEDRICH. Histopathologische Untersuchungen über Entstehung und Wesen der senilen Plaques.** *Zeitschr. Ges. Neurol. u. Psychiatr.* 122(1/2): 291-307. 5 fig. 1929.—The plaques are found in a great variety of conditions; in presenile, senile and arteriosclerotic dementia, but also in general paresis and in brains without clinical or pathological evidence of disease. The plaques are products of abnormal metabolism, and it is uncertain whether they are formed locally by the brain or transported there metastatically through the blood stream. But whether they are local or hematogenous products, they must be considered as "foreign bodies" which provoke reactions on the part of the surrounding tissue; in this respect they differ from the corpora amylacea, which produce no reactive changes. On this basis, the author disposes of the theory of various authors that the plaques are formed by microglia, oligodendroglia, or astrocytes. These latter cells do not produce the plaques but merely react to them as scavengers (microglia) or as supportive cells (astrocytes). Neither the plaques nor the feltwork that usually forms their radiating outer layer is necessarily connected with blood vessels. They may be totally independent of vascular structures. But in the majority of instances they are

perivascular. Ganglion cells or glia cells are unable to form plaques. The "nucleus" of the plaque usually contains lipoids.—*A. A. Low.*

16352. **TOWNE, EDWARD BANCROFT, and FREDERICK LEET REICHERT. Compression of the lumbosacral roots of the spinal cord by thickened ligamenta flava.** *Ann. Surg.* 94(3): 327-336. 13 fig. 1931.—A new cause of compression of the spinal cord is reported, with 2 illustrative case histories. The condition is a proliferation of the ligamenta flava between laminae of the lumbar spine, which eventually causes a block in the cerebrospinal fluid circulation and compression of the cauda equina; the etiology is unknown.—*From author's summary.*

16353. **WALLBACH, GÜNTER. Untersuchungen über die unterschiedliche Wirkung einiger leukocytenvermindernder Substanzen.** *Zeitschr. Ges. Exp. Med.* 68(5/6): 621-655. 7 fig. 1929.—In rabbits benzol destroys the follicles of the lymph nodes and spleen and inhibits new growth of the granular leucocytes without stimulating differentiation. In the peripheral blood there is a relative increase in the number of young forms. The bone marrow becomes aplastic, with the persistence of a small lymphoid cell with a heavily stained nucleus in the parenchyma and occasionally in the peripheral blood. There is no histological evidence of cell destruction. Thorium x produces an aplasia of the bone marrow with inhibition of new growth but there is some stimulation to differentiation, so that the peripheral blood shows older forms with no histologic evidence of destruction of leucocytes. The pouring out of lymphocytes results in a decrease in size of the follicles in the lymph nodes and spleen. 200 R of roentgen-ray produces very little change in the lymph follicles and does not reduce the leucocyte count. There is an increase in the number of eosinophils and mast cells in the blood and bone marrow. With 600 R there is a mild decrease in the number of leucocytes with some destruction of the lymph follicles and bone marrow. Granulopoiesis is stimulated by general irradiation, with increase in the number of young forms in the blood stream. The number of eosinophils and mast cells is not increased as much as with weaker doses. The response in the rabbit is apparently different from that in leukemia of man.—*R. Isaacs.*

16354. **WERTHEMANN, A. Experimentelle Röntgenschädigungen des Herzmuskels.** *Strahlentherapie* 38 (4): 702-709. 6 fig. 1930.—In 2 series of experiments on 11 rabbits, the observed x-ray injuries to the heart muscle may be summarized as follows:—(a) Injuries to parenchyma: (1) simple cloudy swelling with loss of cross striations; (2) fine-grained up to coarse nodular, occasionally waxy degeneration, with the fibrillar striations sometimes preserved and sometimes lost; (3) atrophy of muscle fibers, up to complete obliteration, leaving only the empty sarcolemma; simple atrophy of the nucleus, with more marked effects in the degenerated portions. (b) Changes in the interstitial connective tissue: (1) perivascular and extensive diffuse inflammatory infiltration; (2) miliary callus formation, which may lead to actual sclerosis.—*Author's summary (transl. by E. H. Quimby).*

16355. **WILLIS, RUPERT A. Metastatic tumours in the thyreoid gland.** *Amer. Jour. Path.* 7(3): 187-206. 12 fig. 1931.—From evidence in 10 cases observed and 47 previously recorded, the author concludes that different types of tumors possess different intrinsic capacities for establishing metastases in the thyroid; that melanoma and lung carcinoma are the most potent in this respect; that adenomatous and other abnormal areas of thyroid tissue are predisposed to the establishment of metastatic neoplasms, and that this predisposition depends on chemical or metabolic rather than on vascular changes in the altered tissues. In those neoplasms which display a maximum propensity for metastasizing to the thyroid (melanoma and lung cancer), notable association of the metastases with other abnormalities of the gland are observed only infrequently. Conversely, thyroid metastases from growths of low thyroid-colonizing tendency exhibit remarkably frequent association with pre-existing abnormalities of the organ.

16356. **WIŠKOVSKÝ, B. Über die durch Tonsillenreizung experimentell erzeugten Veränderungen des weissen Blutbildes.** *Acta Oto-Laryngol.* 15(2/4): 172-198. 2 fig. 1931.—Cauterization of the tonsils produced in 31 subjects (7 with normal tonsils) changes in the white blood picture like those produced in 4 subjects (3 with normal tonsils) by massage, and observed by Viggo Schmidt after tonsil massage in his own subjects. The leukopenia in the peripheral blood, however, was apparently not dependent on the condition of the tonsils alone, for it occurred both in normal subjects and in those with chronic tonsillitis; the author regards it as due to a restriction of the delivery of lymphocytes to the bloodstream, occasioned by a functional disturbance of the lymphadenoid system through irritation of the tonsils. The tonsils thus appear to be "feelers" of the lymphadenoid system, which under physiologically normal conditions can react to tonsillar irritation by influence on the white blood picture.

Tuberk.* 75(1/2): 313-320. 1930.—From a study of 363 patients Alexander concludes that the endocrine processes which govern menstruation, rather than menstruation itself, exercise an important influence on the course of tuberculosis in women.

16359. **ALVAREZ, WALTER C. Nervous indigestion.** 300p. Paul B. Hoeber, Inc.: New York, 1930. Pr. $3.75. —Although functional types of indigestion are common, they are poorly understood and poorly treated and medical students are graduating without sufficient experience in regard to them. This book has been written with the hope of repairing this defect in medical education. Some of the chapters deal with the physiologic aspects of the problem while others cover the psychologic, sociologic and therapeutic aspects. Detailed instructions are given for the handling of the nervous patient and for the treatment of the various symptoms which may arise. The book is written simply and interestingly enough so that it may be read also by intelligent laymen.—*W. C. Alvarez.*

16360. AMBROGIO, A. Ricerche biologiche in alcuni casi di lebbra. (Nota preventiva.) [Biologic studies on some cases of leprosy. (Preliminary note.)] *Gior. Ital. Derm. e Sifil.* 71(4): 1292-1301. 1930.—Results of serum flocculation and precipitation tests by 12 different methods, erythrocyte sedimentation tests, various tests of the cerebrospinal fluid and urine, etc., on 11 lepers and 50-250 normal controls.

16361. BARELLI, L. Die Wirkung des bestrahlten Ergosterins (antirachitischen Vitamins) auf den Mäusekrebs. *Zeitschr. Krebsforsch.* 29(4): 376-388. 1 fig. 1929.—The administration of irradiated ergosterol to mice inoculated with the Ehrlich carcinoma resulted in a certain degree of inhibition of tumor growth, an effect which the writer attributes to the known restraining effect of Ca on neoplastic growth, and the effect of this vitamin on Ca deposition.—*H. E. Eggers.*

16362. BASTOS, M., und L. MAZO. Ca-Gehalt des Blutes und chronischer Gelenkrheumatismus. *Arch. Klin. Chir.* 161(1/2): 222-232. 1930.—The authors examined the Ca content of blood from 30 clinically recovered individuals from 18-31 years of age. In all these cases, as in pathological ones to be reported later, the Ca determinations were always made in duplicate. Extreme values were: maximum 10.88, minimum 10.03, with a mean value of 10.31 mgm. % in blood serum. The authors have the impression that the normal Ca content is much more constant than earlier figures indicate. They determined the Ca content in patients having chronic articular rheumatism of distinct forms. The figures are as follows: 1) Ankylosed polyarthritis. In 12 patients belonging to this group the Ca value varied between 9.99 and 13.72, the mean value 11.35 mgm. %, a little higher than normal. 2) Monarticular arthritis deformans. In 10 patients the Ca value lay between 10.21 and 13.56 mgm. %, with the mean value 11.53. The Ca content of the blood was above normal and indeed somewhat higher than in group 1. 3) Progressive but not ankylosed polyarthritis deformans. In this group only 2 were examined; the Ca value lay between 10.88 and 12.70, mean value 11.79 mgm. %; above normal and higher than both of the first groups mentioned. 4) Rheumatism or post-infectious secondary arthritis without deforming bone lesions (8 cases). The Ca values were 9.57 and 11.17 mgm. % with a mean value of 10.31, a normal figure. In general it may be said that the Ca value in chronic articular rheumatism is variable while for completely recovered individuals it is constant. Variability corresponds to the rate of the bone change which belongs to the picture of rheumatic disease and it is concluded that the unstable Ca values are not the cause but the result of the disease process. The high Ca content in the blood in this malady is accounted for on the supposition that the lime of the blood is in transit from one point which decalcifies to another which ossifies. —*Authors' summary (transl. by J. C. Bugher).*

16363. BENEDICT, ETHEL M., and KENNETH B. TURNER. The serum calcium in polycythemia vera. *Jour. Clin. Investigation* 9(2): 263-264. 1930.—From a study of 9 cases Benedict and Turner conclude that there is no significant variation in the serum Ca in polycythemia vera.

16364. BERNOCCHI, FILIPPO. Il bilancio tossico e la reazione nera nei neurastenici. [The toxic equilibrium and the black reaction in neurasthenics.] *Cervello* 9(5): 266-277. 1930.—The "toxic equilibrium" (Condorelli's concept of a general formula expressing the degree of intoxication and of the resistance of the organism expressed in terms of the urinary total cholesterol: fatty acid ratio) was subnormal in 11 out of 15 cases of neurasthenia. Buscaino's "black reaction" (black precipitate from urine boiled with $AgNO_3$) was positive in only 2 cases. This "black reaction" expresses a special type of intoxication with substances of the amine group, while the Condorelli toxic equilibrium is of general application, based on the theory that cholesterol is antitoxic and antihemolytic, while the fatty acids are hemolytic and cytotoxic. The cholesterol rises and falls with the defensive reserves of the organism while increase of the fatty acids represents a toxic alteration in metabolism. Hence the apparent discrepancy between the results of the 2 tests is not a real contradiction; it merely shows that a general toxic condition is present in neurasthenia, but not the special kind indicated by the Buscaino test.

Electrical energy, light energy.] 657-1095p., 207 fig. Julius Springer: Berlin, 1928. RM. 48.

16366. BULGER, HAROLD A., HENRY H. DIXON, and DAVID P. BARR, (with the technical assistance of OLIVE SCHREGARDUS). The functional pathology of hyperparathyroidism. *Jour. Clin. Investigation* 9(1): 143-190. 1930.—A study of 3 cases of hyperparathyroidism, 2 with osteitis fibrosa cystica and the other with multiple myeloma, has presented certain abnormalities of Ca and P metabolism. Most characteristic of these were a high serum Ca, possibly accounting for many of the clinical features, and an excessive excretion of Ca by the kidneys, apparently explaining the urinary tract complications. The increase of Ca in the urine was sufficient to cause a negative Ca balance, although 2 patients showed, in addition, an excessive output in the stools. Low serum P was repeatedly found except in 1 patient with marked kidney insufficiency. Altered P metabolism was encountered but no specific abnormality presented. There was no indication that the total N metabolism or creatinine metabolism is abnormal in hyperparathyroidism. Although there were marked changes in Ca and P other serum electrolytes were normal. By the administration of orthophosphate it was possible to cause an increase in the serum phosphate, a decrease in serum Ca, a reduction of Ca in the urine to normal and establish a positive Ca balance. It appears, however, that a continuation of this procedure resulted in an excessive output of Ca in the stools. Following parathyroidectomy in 2 patients the disturbances of Ca and P metabolism were reversed. The Ca almost disappeared from the urine and large amounts of Ca and P were retained in the proportion in which they occur in bone. One patient reverted to tetany which was almost fatal. It was controlled with difficulty by the administration of large amounts of parathormone and Ca. The metabolism of hyperparathyroidism differs almost completely from that of osteomalacia. In the literature, however, great confusion exists in nomenclature. Cases have been called osteomalacia which probably were examples of hyperparathyroidism. This state is perhaps most often seen with von Recklinghausen's disease of bones, but accompanies hyperplasia of the parathyroid from a variety of causes which include multiple myeloma, extensive carcinoma of bone and possibly other destructive bone processes. These studies indicate that improvement in the clinical state of hyperparathyroidism may be accomplished by the administration of orthophosphate. The possible dangers of such a procedure have been made evident. It would appear that the only effective method of treatment is the removal of parathyroid tissue.—*Authors' summary.*

16367. BURGHI, SALVADOR E. L'acidose de la première enfance. Contribution à l'étude clinique de sa pathogénie. *Rev. Française Péd.* 6(3): 335-354. 1930.—In 45 cases (infants aged 1-14 mos.) acidosis occurred exclusively among dystrophic, dehydrated infants, almost always artificially fed, at least in part. Dystrophy, though essential to acidosis, was not sufficient of itself, even when severe, to produce it. In all cases of acute, intense dehydration, however, acidosis appeared.

16368. CASPARI, W. Rohkost und Krebskrankheit. *Zeitschr. Volksernähr. u. Diätkost* 6(3): 38-41. 1931.—From a review of the literature the author believes it

not impossible that a relation exists between the increase in spread of cancer and the constant increase in the use of raw foods as constituents of the daily diet.

16369. **CASTELLINO, PIETRO G. La creatina e creatinina nelle dermatosi. [Creatin and creatinin in dermatoses.]** *Gior. Ital. Derm. e Sifil.* 71(2): 442-448. 1930.—In 19 cases of dermatosis presence of creatin and increase in creatinin content of the urine were observed only in extensive or acute dermatoses, and then not so regularly as to establish a clear relation between the condition of the skin and endogenous metabolism.—*Author's summary (transl.).*

16370. **CASTLE, WILLIAM B., WILMOT C. TOWNSEND, and CLARKE W. HEATH. Further observations on the aetiological relationship of achylia gastrica to pernicious anaemia.** *Lancet* 218(5568): 1062-1063. 1930.

16371. **CHAPIN, HENRY DWIGHT, and LAWRENCE THOMAS ROYSTER. Diseases of infants and children.** 6th rev. ed. 675p. 15 col. pl., 184 fig. Wm. Wood & Co.: New York, 1929. Pr. $7.50.—This volume on clinical pediatrics not only incorporates what is usually found in text-books, but also draws on the authors' clinical experience and their familiarity with the newer knowledge on the subject. Most of the illustrations are original. There is no bibliography.—*L. W. Sauer.*

16372. **CORDS, RICHARD. Zur Pathologie der Führungsbewegungen.** *Graefe's Arch. Ophthalmol.* 123(2): 173-218. 12 fig. 1929.—The author investigated the associated eye movements (nystagmus) in a large series of nerve cases, finding in these the symptom "Sakkadierung" (nystagmus) to which the author called attention in 1925. The patient is unable to follow slowly moving objects evenly, distinctly intermittent movements being noted. Pure "Sakkadierung" without other associated nervous disturbances was found only after epidemic encephalitis (cogwheel phenomena). With directional viewing he found combined "Sakkadierung" in cases of brain stem affections, as well as in encephalitis and multiple sclerosis. In cerebral involvement "Sakkadierung" from right to left points to lesion in the right hemisphere, from left to right in the left hemisphere. "Sakkadierung" from right to left is mostly accompanied by failure of the optico-kinetic eye movement to the right. The author sets up the hypothesis that the associated eye movements are controlled over separate cortical pathways, excitation of movement by one and inhibition of movement by another. The movement from right to left is controlled through the optic motor cortex in the vicinity of the calcarine fissure. Destruction of this portion of the cortex or blocking of the pathway from this area leads to the development of the above symptoms. This is conceivably of importance in cerebral localization.—*R. Cords (transl. by W. F. Jacobs).*

16373. **CRISTOL, PAUL. Interprétation des valeurs de la réserve alcaline du plasma sanguin au cours des céto-acidoses.** *Compt. Rend. Acad. Sci. [Paris]* 188(22): 1451-1452. 1929.—Normal or increased alkaline reserve findings in cases of ketosis, frequently encountered in diabetics, must be interpreted as errors in technique due to the accumulation of diacetic acid in the blood.

16374. **CROSTI, A. Su alcune caratteristiche biochimiche del sangue e degli essudati cutanei in dermatosi. II. Osservazioni comparative nel pemfigo su cute clinicamente normale o alterata. [Some biochemical characteristics of the blood and cutaneous exudate in dermatosis. II. Comparative observations of the clinically normal and altered skin in pemphigus.].** *Gior. Ital. Derm. e Sifil.* 71(4): 1031-1053. 1930.—Studies on 7 patients with pemphigus and Duhring's disease showed no important modifications in the blood, but emphasized some interesting constitutional differences between plasma and cutaneous exudate. Some crystalloid substances, especially Na, are contained in these exudates generally in higher concentration than in plasma, with a perceptible increase in Cl; this high concentration generally corresponds to a rather high refractive index and relatively high protein values (though always lower than those of plasma), and also increase of residual N and of H ion concentration. The vesicular contents in Duhring's disease (except for a slightly higher Ca-content) are almost identical with those in true pemphigus. No significant difference was seen between the exudates from spontaneous and those from artificially produced vesicles. More noteworthy differences were observed between vesicles produced on normal skin and skin clearly undergoing acantholysis, which latter were almost always higher in crystalloids and colloids than the former exudates, even though the index of inflammatory reaction was proportionately no higher. This, Crosti suggests, may be due to the cellular degeneration of the epidermis, producing a local accumulation of comparatively acid protein split products, and thence a state of local hyper-ionization, attracting particularly hydrophil electrolytes and thus tending to increase the protein-salt content of the exudates formed directly over the altered cellular elements.

16375. **DAS, K. K. A note on blood changes in filariasis.** *Indian Jour. Med. Res.* 18(3): 813-816. 1931.—The variation in the percentage of hemoglobin is between 62 and 84, average 74, in the positive cases, and 62 and 80, average 68, in the negative cases. The normal mean hemoglobin value in the adults of Gaya district varies between 72 and 75% (Korke, 1927). It appears therefore that there is no marked fall in the hemoglobin percentage from the standard. The mean value of the red blood cells per c.mm. is normal in the positive (5,440,000) and negative (5,198,000) cases of filariasis. Similarly the mean value of the white blood cells per c.mm. (day and night counts) is nearly normal (positive cases, average, 6,743; negative cases, average, 6,675). There appears to be no appreciable difference between the differential leucocytic count made during the identical hours of day and night, except for the fact that the eosinophil cells show a tendency to rise and polymorphonuclear cells to fall, both in the positive and negative cases of filariasis. This change appears to be due to filariasis, as the presence of helminthic ova found in the cases appears to be negligible. The number of microfilariae in the peripheral blood does not seem to influence the normal value of the red cells; but there is a suggestion in the case of white cells which are below normal (vide cases 4, 5 and 12, Table I).—*Author's summary.*

16376. **DIETHELM, O. Disturbance of vision and consciousness in Petit-Mal attacks.** *Human Biol.* 2(4): 547-554. 1930.—With hypnotic technic petit-mal attacks of various epileptic patients were investigated. The rehearsal of these attacks in deep hypnosis revealed characteristic changes in consciousness, vision and bodily sensations. Consciousness was found to be very fluctuating. At times it was clear, at others appreciation of surrounding objects was vague, passing at some points into a complete loss of external perception. In all attacks there were sensations of tightness, tenseness and numbness, most frequently in throat and face. They appeared from a few minutes to 2 hrs. before the attack and lasted for a varying period up to 10 minutes after the attack. The patients did not experience those sensations in their conscious state, and the variation in intensity was not correlated with any variation in consciousness. There was a definite concentric constriction of the field of vision on entering the attack and a similar concentric enlargement on coming out. There was further restriction of attention to the central objects, loss of the sense of the situation and location, and disturbance of fusion. Similar findings were observed in a patient who did not lose consciousness during his attacks.—*O. Diethelm.*

16377. **DODDS, E. C., and J. D. ROBERTSON. The relation of aceto-acetic acid to diabetic coma and the cause of death.** *Lancet* 218(5564): 852-854. 1930.—The alkali reserve of the blood was estimated by the Van Slyke method, great care being taken to insure uniformity in the determinations. Saturation of the specimen with CO_2 was performed by a gas mixture containing 5.5% CO_2 in air in a cylinder. The acetone bodies

in the blood were estimated by the method of Behre Benedict in the form of volatile and non-volatile acetone bodies. Since the blood contains little or no acetone these estimations correspond respectively to aceto-acetic acid in β-hydroxybutyric acid. A study of (a) the aceto-acetic acid and (b) the alkali reserve content of the blood in patients in diabetic coma failed to support the theories of ketosis and acidosis respectively as a cause of this condition. Thus, in many cases non-comatose diabetic patients were found to have a higher aceto-acetic acid content than the comatose patients, and it was found impossible to correlate the blood analyses with the clinical condition of the patient. On recovery from coma the aceto-acetic acid content rose, thereby further indicating that the enol theory of diabetic coma is improbable. In the fatal cases death was preceded by a persistently falling blood pressure, and the importance of circulatory failure is indicated. The occurrence of leucocytosis in coma is confirmed.—*Authors' summary.*

16378. Du BOIS. Cancers de la face avec granulômes à cellules géantes et corps étrangers. [In French, with English summary.] *Acta Dermato-Venereol.* 11(3): 268-276. 3 fig. 1930.—In 2 cases basocellular growths developed in the immediate neighborhood of foreign bodies, 1 of these being the sting of an insect that had been lodged for 5 yrs. in the skin at the point where the tumor made its appearance, the other a spine, probably of vegetable origin, of the date of whose lodgment nothing positive could be learned. Good microphotographs show both these foreign bodies surrounded by giant-cell granulomata in the immediate neighborhood of the 1st manifestations of a cancer. The author therefore holds that spontaneous cancer of the face should be given an important place side by side with those conditions which develop from the classical precancerous affections, and that to the list of etiological causes there should be added that of "insidious penetration into the skin of various foreign bodies." Other observations still in progress seem to show that a similar rôle can be played by foreign bodies of endogenous origin.

16379. EAVES, ELIZABETH COWPER. Diabetes insipidus. *Brain* 53(1): 47-55. 1 pl. 1930.—Report of 4 cases of diabetes insipidus, 1 associated with infantilism, 1 post-encephalitis, 1 transitory post-encephalitic, 1 transitory without nervous disease. The author states that diabetes insipidus may be due to a transient affection of the pituitary, which may recover its function completely; or it may be present as a permanent condition as, for instance, a congenital defect; that neither hyperplasia of the pars intermedia nor the pars tuberalis causes this condition but that a relatively mild lesion in the hypothalamic region of the brain may cause diabetes insipidus. This may be due to a stimulation of an inhibitory center or tract—to the pituitary, thus causing inhibition of secretion of the posterior lobe hormone. A severe lesion in the hypothalamus in contradistinction to a milder one does not bring about diabetes insipidus. —*H. J. John.*

16380. ECKSTEIN, H. C., and UDO J. WILE. Lipid studies in xanthoma. *Jour. Biol. Chem.* 87(2): 311-317. 1930.—The nature of the lipids in a xanthomatous tumor has been determined and compared with that of the lipids in the tissue adhering to the tumor and with those in normal subcutaneous fat. The fatty acid make-up of the lipids in the tumor differs markedly from that of those in normal subcutaneous fat and the lipids in the tissues adhering to the tumor. On the other hand, the nature of the fatty acids in the adhering fat is like that of normal subcutaneous fat. The percentage of cholesterol and phospholipids in the total lipids of the tumor was 48.81 and 8.1% respectively, 200 times the amounts previously found for normal human subcutaneous fat. The percentage of cholesterol in this tumor is considerably higher than the amount previously reported for other xanthomata. In accordance with our previous findings, however, no parallelism between the nature of the blood lipids and those of the tumor could be demonstrated. The nature of the lipids in xanthoma may be more dependent on the activity of the tissue than on the nature of the blood lipids.—*Authors' summary.*

16381. EDMUNDS, CHARLES W., and FRANKLIN D. JOHNSTON. The relation of the adrenals to the circulatory collapse of diphtheria. *Amer. Heart Jour.* 4 (1): 16-20. 1928.—In 4 diphtheritic dogs there was a marked diminution in the amount of epinephrine in the adrenal glands. This decrease in epinephrine was probably not the cause of the circulatory collapse.

16382. FLATAU, EDWARD. Sur l'épidémie d'inflammation disséminée du système nerveux en Pologne durant l'année 1928 et sur ses rapports avec l'encephalite lethargique, les atteintes du système nerveux au cours de certaines maladies infectieuses et les cas aigus de sclérose en plaques. *Encéphale* 24(7): 619-660. 1 pl. 1929.—Seventeen cases, most of them children and young adults occurring in first half of 1928 in Poland, are reported. In patients previously well, there is sudden onset of paralysis in one or more limbs and peculiar paraesthesia of bizarre distribution. Transitory peripheral facial palsies and clouding of vision were noted. More rarely during period of invasion diplopia and in 1 case dysphagia and hoarseness; in a few splenic disorders. In most of the cases there was no fever during onset and constitutional symptoms were usually minimal. After a few days the subjective sensory phenomena regressed, rarely being stubborn and persistent. The motor paralysis became more definite with pyramidal tract signs; the frequency of a positive even bilateral Ressolimo in the absence of the Balruski's sign is considered worthy of special mention (in 13 of 17 cases). In 2 cases tendon reflexes in the lower limbs were absent; the abdominal reflexes, especially the lower, were often lost. The pupils reacted well to light and accommodation; disorder of conjugate movement of the eye was observed, especially limitation upward; occasional diplopia and ocular palsy and in 3 cases nystagmus. In 3 cases sympathetic phenomena were recorded: narrowed palpebral fissure with miosis in one, a narrowed fissure only in one and a shiny facies in the last. There were no significant findings in the spinal fluid. Injection of it into guinea pigs was negative. Pathologically only 1 case was studied and it showed infiltration of the central ganglia, spinal cord and peripheral nerve. There was a definite neuroglial response with tendency of the glia cells to accumulate around the blood vessels. Infiltration of the leptomeninges especially at the base of the pons was recorded. Since the epidemic of encephalitis of 1918-1920 there has been a significant increase in the number of atypical reports of inflammatory diseases of the nervous system. Some of these are definitely "low forms" of encephalitis epidemica. There have also been more cases of acute and even chronic multiple sclerosis, increased frequency of central nervous system complications of acute infections, diseases like scarlet fever, measles, varicella; all these infections may be due to the same filtrable virus.—*N. Savitsky.*

16383. FLEISCHER, BRUNO. Zur Ätiologie des Keratokonus. *Arch. Augenheilk.* 100/101: 247-267. 1929.—Three cases of keratoconus arising from different causes are described in detail. Cases from the literature are discussed. It is concluded that there are many disorders both general and local which may produce keratoconus. It may arise from hereditary causes, nervous conditions, glandular disturbances, local injuries and as a result of such ocular diseases as juvenile cataract and retinitis pigmentosa.—*C. E. Keeler.*

16384. FONTANA, G. La circolazione arteriosa del rene idronefrotico. [Arterial circulation of the hydronephrotic kidney.] *Ateneo Parmense* 2(4): 312-328. 8 pl. 1930.—In experiments on 19 rabbits, the arterial renal circulation was profoundly and progressively influenced by the changes of hydronephrosis. As shown by x-rays of the injected arterial tree, the inter-arterial spaces were progressively dilated while the caliber of the vessels contracted and the terminal arborescence finally disappeared altogether.

16385. **FREUND, HELMUTH.** Darier-ähnliche Atypie eines Keratoma senile mit Blasenbildung. [A senile keratoma with atypical resemblance to Darier's disease and vesicle formation.] *Arch. Dermatol. u. Syph.* 162 (3): 733-738. 3 fig. 1931.

16386. **FUJINO, SANAE.** Über Blutzucker bei Hautkrankheiten. [In Japanese, with German summary.] *Acta Dermatol.* 16(6): 552-567. 1930.—The blood-sugar was studied by the Hagedorn-Jensen micromethod in 87 cases of various skin diseases (21 cases of vitiligo vulgaris, 11 of acne, 10 of sycosis vulgaris, 5 of lupoid sycosis, 8 of alopecia areata, 5 of urticaria, 3 of psoriasis, 5 parapsoriasis, 5 of keratodermia tylodes palmaris progressiva Dohi, 4 of chronic eczema and 1 each of various other diseases). When the blood-sugar was determined in the morning fasting and every 30 min. for 2 hrs. after a Sakaguchi test breakfast, a more or less marked rise was observed in 37% of the cases. After ingestion of 100 gm. levulose there was a rather protracted rise in 47% of the cases. After injection of epinephrine (1 mgm. in men and 0.7 mgm. in women) there was a marked hyperglycemia in 51% of cases. These results tend to sustain the theory of a latent and intermittently patent carbohydrate disturbance in various skin diseases, which may rise to the point of a pathologic hyperglycemia and sugar intolerance.—*From author's summary (transl.).*

16387. **GADE, F. G.** Further investigations on the cancerous diseases in Norway (1912-1926). *Skrifter Norske Videnskaps-Akad. Oslo, I. Math.-Naturv. Kl.* 1929 (paper 10): 1-24. 2 maps. 1930.—During the period 1912-26 the general mortality in Norway declined from 13.5 to 10.8 pro mille; but at the same time the deaths from malignant tumors increased from 103.5 to 118.7 pro 100,000 living inhabitants. The reported numbers of cancer-deaths may be augmented by ca. 15%, as 1.7% of all deaths are not reported by physicians, and at least 12% cancer-deaths are "hidden" under other diagnoses (acute intercurrent diseases, accidents etc.). The period 1919-23 being exactly investigated proves, that of the cancer-tumors 51.67% are localized in the stomach, 66.52% in the alimentary organs as a whole (liver and pancreas included), and 12.07% in the female generative organs (uterus 6.19%, ovaries 0.94%, mammae 4.94%), or 23% of all cancers in women. A striking phenomenon is the nearly identical age-curves for cancer in these organs, themselves so different as to histological and physiological qualities, all of them having an early maximum death-rate about the age of 50-55 years, the menopause, their local and functional senility; a fact which may be considered as a manifestation of a biological law. There is a slight preponderance for cancer with women (109.2 per 100,000, against 105.9 with men), particularly noticeable in the earlier periods of life, 20-60 years, and here to some degree caused by the early "female cancer," which also perhaps may be responsible for the smaller number of cancer ventriculi with women than with men, the cancer-disposed women having mostly succumbed before the 60th year, the maximum for c. ventriculi. In the very homogenous Norwegian population some racial influence may be presumed, as the relatively greatest number of cancer deaths occur in those parts of the country where the dolichocephalics are in majority.—*F. G. Gade.*

16388. **GLANZMANN, E. Röteln und Drüsenfieber (Benigne Lymphoblastosen).** *Schweizer. Med. Wochenschr.* 59(17): 445-454. 1929.—Some cases of German measles pass without fever. After fever develops it may decrease rapidly or it may increase. In the prodromal stage the symptoms are catarrhal conditions, conjunctivitis, sneezing and often severe headache. An intense reddening on the face is often the first symptom. A red eruption forms behind the ears and on the forehead and nose, and spreads rapidly. The number of leukocytes decreases. Eosinophiles do not disappear. 5 types are distinguished: septic, membranous angina, pharyngeal, abdominal, and subfebrile.—*P. G. Heineman.*

16389. **GOLDBLOOM, ALTON, and RUDOLF GOTTLIEB.** Icterus neonatorum. III. The oxygen capacity and saturation of the mother and foetus. *Jour. Clin. Investigation* 9(1): 139-142. 1930.—From a study of 25 cases the authors conclude that fetal arterial blood (umbilical vein) possesses an increased O capacity and a diminished O saturation. This diminution in O saturation of the blood in the umbilical vein is to be accounted for by the deficient respiratory function of the placenta. Maternal blood from the radial artery shows values for capacity and saturation which are within normal limits. Further evidence is thus adduced in support of the theory that the polycythemia in the newborn infant is the result of O unsaturation of the fetus in utero.

16390. **GRABFIELD, G. P.** Studies on the nitrogen and sulphur metabolism in "Bright's disease." I. The retention of nitrogen and sulphur in "nephrosis." *Jour. Clin. Investigation* 9(2): 311-318. 1930.—The N and S excretion of 5 patients exhibiting the nephrosis syndrome was studied while these patients were on a diet constant as to N, S, P, calories and water. As in other studies a large retention of N occurred. The retention of S was greater than that of N regardless of the level of dietary N. The N:S ratio in the urine was high. The N:S ratio of the "retained protein" was low.—*Author's summary.*

16391. **GREEN, M. F., and M. M. KUNDE.** The acidity of the gastric contents of normal, cretin and hyperthyroid rabbits. *Amer. Jour. Physiol.* 95(3): 626-629. 1930.—The concentration of HCl of the gastric contents (normal and histamine induced) of cretin rabbits, with severe anemia and cachexia, is the same as in normal rabbits. The HCl of the gastric contents of rabbits with experimental hyperthyroidism is depressed but not absent. The total HCl of the gastric contents of normal and cretin rabbits ranges from 0.2 to 0.56%.—*Authors' summary.*

16392. **HARDY, T. L.** The rôle of hydrochloric acid in the causation of gastric pain. *Lancet* 1(5510): 711-713. 1929.—HCl in concentrations of 0.5% will reproduce typical gastric pain, independently of any gastric or duodenal disease, in certain susceptible individuals suffering from painful disturbances of gastric function. HCl, in Hardy's opinion, plays no essential part in ordinary pain production.—*From author's conclusions.*

16393. **HEINEMANN, H.** Untersuchungen über den Liquor cerebrospinalis. V. *Arch. Schiffs- und Tropen-Hyg.* 32(10): 500-505. 1928.—In syphilis, the Chinese give a distinct positive gold reaction more frequently than the Javanese. This also holds true for leucocytosis and the Wassermann test. These serological findings bring support to the clinical experience that Chinese workmen are more predisposed to syphilis of the central nervous system than are the Javanese.—*S. Katzenelbogen.*

16394. **HEWITT, L. F.** Bence-Jones proteins. *Biochem. Jour.* 23(5): 1147-1152. 1 fig. 1929.—Bence-Jones proteins from 5 cases of myelomatosis were examined and found to differ in their properties. The most marked variation occurred with 2 specimens that did not redissolve in boiling salt solutions. In the presence of 40% alcohol, all the Bence-Jones proteins coagulated when warmed and redissolved when boiled. Serum proteins, however, behaved similarly in the presence of 40% alcohol. The author believes this effect is due to a shift in the apparent isoelectric point with the resulting formation of more soluble salts, rather than due to a solvent action of the alcohol.—*F. C. Bing.*

16395. **HUBBARD, ROGER S.** The excretion of chloride in Achlorhydria. *Jour. Biol. Chem.* 88(1): 361-366. 1930.—In a series of cases of achlorhydria a low rate of excretion of NaCl during the hour following the morning meal can be clearly demonstrated. A relatively high rate of chloride excretion immediately after awakening can also be shown in such subjects. These variations seem to be independent of variations in the rate of water excretion.—*Author's summary.*

16396. **HUBBARD, ROGER S.** The association of

renal and gastric disorders with constancy of the urinary reaction. *Jour. Clin. Investigation* 9(1): 37-41. 1930.—Of 296 patients on whom determinations were made, 173 failed to show an alkaline tide as defined by Munford and Hubbard. From consideration of clinical histories and laboratory findings in these 173 patients Hubbard concludes that: (1) relative constancy in reaction of the morning urine is often associated with an absence of HCl from the gastric juice; (2) constancy in the reaction of the morning urine frequently occurs when no impairment of renal function and no signs of kidney disease can be demonstrated; (3) although there is some evidence that an absence of the early morning period of alkalinity may be associated with diseases of the kidneys the relationship is not an essential one.

16397. **IWATA, MOTOE.** On the occurrence of lysolecithin in polished rice. *Proc. Imp. Acad.* [*Tokyo*] 6 (5): 212-215. 1930.—Lyso-lecithin ("a toxin formed from lecithin through the action of lecithinase of cobra venom") was isolated from polished rice. Its relation, if any, to beriberi is undetermined.

16398. **JOHNSON, SCOTT, and WALTER J. SIEBERT.** Experimental myocarditic lesions in the rabbit. Their effect on myocardial abscess from intravenous injection of staphylococci. *Arch. Path.* 6(1): 54-66. 3 fig. 1928.—Injection of caffeine and epinephrine was made slowly into the ear veins of rabbits: 0.2 cc. of 1:1000 epinephrine chloride solution was used and 0.025 gm. caffeine dissolved in 1 cc. of water. The drugs stimulated the capillary endothelium. Newly formed blind pockets sprouted from the capillaries. After drug injection, 2 strains of *Staphylococcus aureus,* one of high virulence and the other of low, were injected into the rabbits intravenously. The virulence of the *Staphylococcus* was increased by drug injection. In 90 out of 100 rabbits definite myocarditis had been produced by the drugs. The drug lesions had a tendency to concentrate in the left ventricle. Myocarditic lesions may be sufficiently severe to interfere with ventricular contraction at the site of the lesion. Even a *S. aureus* culture of low virulence produced abscesses in drug-treated rabbits. In control rabbits virulent cultures of *S. aureus* generally produced lesions. Frequency of cardiac decompensation from the drugs was increased by injection of *S. aureus.* The authors were unable to demonstrate any direct relationship between the acute vegetations of the heart and a lesion of the valves produced by caffeine or epinephrine injections. The presence of a myocarditic lesion may indirectly favor the production of a fibrinous pericarditis and of pneumonia. There was, however, no evidence that these drugs lowered the resistance of the pericardium to bacteria.

16399. **KATSUYA, SH.** The reticulo-endothelial system in obstetrics and gynecology. *Japanese Jour. Obstetr. & Gynecol.* 13(4): 356-426. 19 fig. 1930.—A review of experimental work done on this subject, with comment on its relation to toxemia of pregnancy.

16400. **KOKITA, HARUO.** Experimental studies on transplantable sarcomatoid newgrowths in rats (VIIIth report), especially on the experimental development and formation of the transplantable sarcoma in that animal. With some remarks on the pathology of the future. *Acta Dermatol.* 16(2): 194-212. 1930.—By feeding albino rats infested with *Cysticercus fasciolaris* on rice mixed with an aqueous extract of coal tar, Kokita was able to transform the wall of the parasitic cyst into transplantable sarcoma tissue. The spleen of a rat fed on the rice-coal tar extract diet, though presenting only inflammatory, not neoplastic changes, developed into sarcoma when subcutaneously transplanted into a normal rat. In both clinical cases and animal experiment the author claims to have discovered an "inflammatory-tumorous" tissue change—a gradual change of inflammatory into neoplastic tissue. In the rats this "inflammatory-tumorous" change developed in those fed on coal-tar extract; such tissue, subcutaneously implanted into normal rats, developed sarcomatoid characteristics.

16401. **KRABBE, KNUD H., et OLINE CHRISTENSEN.** Recherches des helminthes dans la sclérose en plaques. *Acta Phychiatr. et Neurol.* 5(4): 509-514. 1930. —Negative findings in the feces in 19 cases.

16403. **LINDER, G. C., J. MAXWELL, and F. H. K. GREEN.** A clinical, pathological and biochemical study of amyloid nephrosis. *Arch. Dis. Childhood* 2(4): 220-230. 2 col. pl. 1927.—The paper contains a clinical, histological and biochemical study of a case of "amyloid nephrosis" in its later stages. The patient was an undersized and deformed boy of 13 yr., with a definite history of edema recurring repeatedly from the age of 4 yr. until death. In the combination of a well marked tendency to edema with a complete absence of hypertension and cardiac hypertrophy the case complied with the requirements for the diagnosis of "nephrosis." It was therefore an example of that condition in the terminal stage which is so rarely seen. On admission (Oct. '25) to the hospital the plasma contained 0.33% cholesterol and by December this had increased to 0.55%. From this time the cholesterol rose steadily, reaching a maximum of 0.92% in May, 1926. This steady rise was interrupted twice; 1st by a fall to 0.40 following a mastoid operation, and 2nd by an irregular depression occupying 7 wks. of uremia and acidosis. With the fall of the blood urea the cholesterol rose rapidly and attained the level which it would have reached if its former rate of increase had not been interrupted. A fat-free diet caused a fall in cholesterol, and the possibility arises that excessive cholesterol may be capable of reduction by such a diet. The occurrence of tetany and of symptoms of salt deprivation is reported.

16404. **McCARRISON, R.** Further researches on lymph-adenoid goitre in rats. IV. *Indian Jour. Med. Res.* 18 (2): 577-597. 4 pl., 1 fig. 1930.—The experimental production of lymph-adenoid goitre in rats, by means of a diet composed of white bread and dried yeast, is confirmed. The average urinary excretion of I by rats fed on this diet was 57γ per litre. Rats fed on this diet are more likely to develop lymph-adenoid goitre during the spring and summer than during the autumn and winter. It is considered that the seasonal incidence of the condition is not determined by the action of temperature per se on the thyroid gland. The addition of slaked lime to the diet of white bread and yeast had no influence on the incidence of the goitres caused by this diet, though it appeared to augment the size of those occurring during the summer months; its addition to the diet during the winter months did not cause an increase in size of the thyroid gland. The addition of I to this diet appeared to increase the incidence of lymph-adenoid goitre in the spring and summer, but not in the autumn and winter, experiments. This condition was most common in rats to whose diet I was added and whose urinary excretion of iodine averaged 122γ per litre. A description of 4 representative specimens of experimentally-produced lymph-adenoid goitre in rats is provided by Williamson and Pearse, who originally described this condition in man. The experimentally-produced lymph-adenoid goitre is identical with that occurring in man. The faults common to the diets hitherto used in the experimental-production of lymph-adenoid goitre are: (a) deficiency of fat-soluble vitamins (A and D); and (b) deficiency of vitamin C. Rats fed on synthetic diets deficient in vitamin C, but complete in other respects, did not develop lymph-adenoid, or other, goitre. Lymph-adenoid goitre occurred in 2 out of 18 rats fed on a diet having the above faults although they were exposed daily to the direct rays of the sun, and were, presumably, acquiring a sufficiency of vitamin D in this way. The average urinary excretion of iodine by rats so treated was 96γ per litre. By a process of exclusion of other vitamins, vitamin A-deficiency would appear to be the chief dietetic factor concerned in causing lymph-adenoid

goitre in rats; but further experimentation is necessary before the relative importance of the fat-soluble vitamins (A and D) can be finally determined. It is pointed out that while vitamin-deficiency appears to be the main dietetic factor concerned in causing lymph-adenoid goitre in rats—without which it has not up to the present been observed to arise—the possibility has to be borne in mind that some unknown positive agency may be associated with the negative one of vitamin-deficiency in the causation of this type of goitre. It would appear from the results of these experiments that in the absence of a sufficiency of fat-soluble vitamins in the diet the thyroid gland is unable to deal with I in a normal way; and, that its administration in these circumstances may actually favor goitre-production. It seems possible that the varying results of I prophylaxis in different individuals may be related to the varying amounts of these vitamins in the diets.—*Author's summary.*

16405. **McCARRISON, R. Further researches on stone. VIII.** *Indian Jour. Med. Res.* 18(3): 903-934. 1 pl. 1931.—Well-fed albino rats living under hygienic conditions are normally free from stone; they develop the disease only when fed on deficient diets. The dietetic factors so far found to be concerned in stone-production in albino rats are of 2 orders: negative and positive. The negative factors are deficiency of fat-soluble vitamins and of phosphates; the positive factors are excess of Ca and an unknown agent present in varying amounts in cereal grains. The positive factors appear to be innocuous unless the negative ones are operative. Malnutrition of the urinary tract was an important underlying cause of the calculous disease occurring in rats in these experiments. Superimposed infection may have contributed to its occurrence; it was not essential to it. In a number of cases cystitis and pyonephrosis occurred without stone, in a number of others stone occurred without cystitis or pyonephrosis. Incrusted cystitis was observed in 8 cases. Although an excess of vitamin D in the diet is known to cause stone in albino rats, the daily exposure of these animals to the direct rays of the sun did not increase the incidence of the disease when they were fed on a stone-producing diet. The incidence of urinary calculus in rats fed on a basal diet of white bread and yeast was 14.6%. The calculi so produced were of the ammonium-magnesium phosphate variety. The addition of slaked lime to the basal diet of white bread and yeast greatly increased the incidence of urinary calculus and of urinary tract infections. It also altered the physical and chemical characters of the calculi, which were no longer well formed nor composed of ammonium-magnesium-phosphate but were ill formed and composed of $CaCO_3$, $Ca(OH)_2$ or both. More lime was deposited in the urinary tract during the winter than during the summer months. The stone-producing potency of this diet (white bread, yeast and lime) was further enhanced by the addition to it of a vitamin-poor vegetable oil; inflammatory states of the urinary tract were also more frequent and more severe, due probably to the greater relative deficiency of fat-soluble vitamins brought about by the presence of this oil in the diet. The further addition of radiostoleum (approximately 0.06 of a drop per rat per day) to this diet caused a great reduction in the incidence of urinary calculus and of urinary tract infections. The stone-preventing potency of this amount of radiostoleum appeared to be related to the concentration of Ca in the diet: the more Ca the less potent the radiostoleum. Radiostoleum did not prevent the deposition of Ca in the urinary tract by limiting the amount of Ca absorbed or passing through the kidneys. Whether it prevented the deposition of Ca solely by maintaining the nutrition and functional integrity of the tissues of the tract and their freedom from infection, or by altering the physical state of the Ca-salts passing through the tract, remains to be determined. A balanced adjustment between the Ca and the radiostoleum was found necessary not only for the prevention of calculous disease but for normal growth of the rats. Vesical calculus was produced in otherwise healthy and well-nourished rats by feeding them for 75 days on a diet of high stone-producing potency and thereafter for 173 days on a diet of which the stone-producing potency was low or nil. Experimentally-produced $CaCO_3$ stones in rats have practically the same composition as urinary calculi in cattle; an observation which may have an important bearing on the etiology of cattle-stone.—*Author's summary.*

16406. **McINTOSH, RUSTIN, LASLO KAJDI, and DOROTHY MEEKER. Blood volume and plasma electrolyte changes in the dehydration of infants.** *Jour. Clin. Investigation* 9(2): 333-357. 1930.—Infants (11) suffering from dehydration associated with diarrhea were subjected to simultaneous determination of total blood volume and serum electrolyte concentration, both during dehydration and after recovery. In acute dehydration some patients showed no essential change in total blood volume, while others showed a 20% diminution of the recovery value. When this reduction was marked, it involved principally the plasma fraction, in 1 instance to the extent of 30%. There was no close parallelism between the diminution of plasma volume and (1) the degree of dehydration of the subcutaneous tissues as determined by clinical criteria or (2) the severity of toxic symptoms. Most of the patients showed during dehydration a decrease in the serum concentration of total fixed base, chloride, and bicarbonate; but the degree of acidosis, as measured by the serum bicarbonate concentration, could not be correlated with changes in blood or plasma volume, since the patient whose plasma loss was greatest for the whole series had a higher bicarbonate concentration on admission than after recovery. Before treatment had been given, the lowering of the total plasma electrolyte content was sometimes even greater than the loss of plasma water, when measured as percentage deviations from the presumably normal values found after recovery. Protein was often included among the electrolytes lost from the plasma during dehydration, so that the composition of the fluid leaving the circulation was comparable to that of plasma of normal protein and bicarbonate content but concentrated in respect to fixed base and chloride. As a check on the assumption that the 2nd set of determinations, made after recovery from dehydration but not always at a time of complete clinical recovery, represented normal values for the individual studied, the figures obtained during dehydration were compared with normal values obtained by applying the same technical procedures to healthy infants. This comparison substantiated the results already expressed.—*From authors' summary.*

16407. **MANDELSTAMM, MAXIMILIAN. Weitere Untersuchungen über die Farbenspeicherung im Zentralnervensystem. III. Mitteilung.** *Zeitschr. Ges. Exp. Med.* 62(3/4): 471-491. 1 fig. 1928.—Trypan blue, injected either intraventricularly or intracerebrally into rabbits, is taken up actively by the mesodermal perivascular cells but poorly by the normal ectodermal elements. Glia cells "activated" by trauma, however, stain well. Failure of generalized staining of the central nervous system on injection into the blood or cerebrospinal fluid can be attributed not to the existence of diffusion barriers between blood and brain, or between cerebrospinal fluid and brain, but to physico-chemical relations (electric charge, adsorption selectivity) between dye and cells.—*V. E. Hall.*

16408. **NEUDA, PAUL. Über Blutfettänderungen beim Luetiker.** *Wiener Arch. Inn. Med.* 21(3): 455-460. 1931.—The increased I tolerance of luetics is traced to changes in blood fats (3 control patients, 5 luetics); chemical analysis showed absolute and relative increase in phosphatides (based on lecithin) in the total fat, sometimes an increase in total fat. The I index in luetics pointed to increased unsaturated fatty acids.

16409. **PURJESZ, B. Zur Frage des Fiebers bei blutenden Magen- und Duodenalgeschwüren und bei Blutverlust.** *Wiener Arch. Inn. Med.* 21(3): 413-426. 1931.—In 84 of 115 patients with bleeding gastric and duodenal

ulcer, fever above 37° axilla occurred. Three dogs were bled ⅓-½ the total volume of blood from the jugular vein; temperature rose; erythrocytes returned to initial value before Hb. Two dogs were given 30 cgm. phenylhydrazine daily; temperature rose, erythrocytes and Hb decreased abruptly. Clinical experience has shown that donors often have rise in temperature together with general malaise. Thus hemorrhage and pronounced decrease in erythrocytes and Hb respectively may produce a rise in temperature which is not caused by resorption from the intestine.

16410. **PUTSCHAR, W., und F. HOLTZ. Erzeugung von Hautkrebsen bei Ratten durch langdauernde Ultravioletbestrahlung.** *Zeitschr. Krebsforsch.* 33(3): 219-260. 1 fig. 1930.—The writers were successful with great regularity in producing skin cancers of the ears, and less frequently of the backs, of rats, by ultra-violet irradiation, without the adjuvant action of chemical agents. The earliest appearance of the cancers was after 27 weeks of irradiation. After 37 weeks cancer was observed in all of 6 animals. There was no certain association between color and cancer susceptibility. Addition to the diet of irradiated ergosterol was without effect. Alterations of the elastic tissues seen were purely degenerative in character, had no relation to cancerization, and were a manifestation of the dermatitis. As a specific effect of the irradiation there was observed periodical regeneration of the hair, with pronounced overgrowth of wool hairs and the formation of giant hairs. There is a close histological connection between the precancerous light dermatoses of the human and sunlight cancers, and these experiments demonstrate the etiological importance in this connection of the ultraviolet rays. There was little evidence that these experimental cancers originated in embryonal cell types; the process appeared to be one of chronic irritation with long-continued katabiotic processes.—*H. E. Eggers.*

16411. [RABUKHIN, I. E.] РАБУХИН, И. Е. Об углеводном обмене при ТБК легких. [Exchange of carbohydrates in pulmonary tuberculosis.] [French summary.] Вопросы Туберкулеза [*Voprosy Tuberkuleza*] 7(8): 935-944. 1929.—Blood sugar in tuberculous patients (empty stomach) was usually normal. Only in diffuse nodose and exudative forms was there a tendency towards hypoglycemia. Blood sugar in Tb. varies with the process. Glucose per os and per venam showed that in all forms of extended pulmonary tuberculosis the normal sugar regulation is disturbed. In cirrhotic processes hyperglycemia was very marked; in exudative and nodular ones, there is also a retarded combustion of glucose. This disturbance does not depend on intestinal and assimilatory processes. No hyperfunction of pancreas was observed; there is rather a hypofunction of the suprarenal and thyroid glands. This assumption is supported by the tonus of the sympathetic nervous system. In benign forms there is either normal- or hypersympathicotonia; in grave, diffuse processes—hyposympathicotonia. The glycopoietic and assimilatory function of the liver plays a large part in the disturbed carbohydrate metabolism. On the whole, carbohydrate exchange in tuberculosis was lowered, justifying insulin therapy of certain forms of Tb.—*B. Van Rosen.*

16412. **ROFFO, A. H. Durch Tabak beim Kaninchen entwickeltes Carcinom.** *Zeitschr. Krebsforsch.* 33(4): 321-332. 1 fig. 1931.—Report of the production of a squamous cell carcinoma of the rabbit's ear by application of a watery solution of the combustion products of tobacco, in one of 10 animals. The applications were made daily, and 8 mos. were required. Parallel experiments with a solution of nicotin, and with a distillate from the residue after nicotin extraction, resulted negatively. The possibly active substances contained in the cancerogenic preparation were essential oils, pyridine, empyreumatic substances, along with potassium carbonate, bicarbonate and nitrate.—*H. E. Eggers.*

16413. **RUSSETZKI, J. J. Untersuchungen über den Kniesehnenreflex beim Menschen. II. Über den Kniesehnenreflex bei cerebraler Hemiparese und Parkinsonismus.** *Arch. Psychiatr. u. Nervenkrankh.* 86(5): 694-723. 1929.—Reflexometric examination, according to the method of the author (Arch. f. Psych. u. Nervenkrankh. 86, 1928), was made in 16 cases of cerebral hemiparesis and 10 of postencephalitic parkinsonism. The cases of cerebral hemiplegia, by the removal of inhibitory processes, showed an increase in the amplitude of the reflex movements (particularly return movements), an increase in the number of these movements and an inversion of the reflex formula (−+). Flexion at the knee produced the same reflex formula, −+. The parkinsonian patients presented variations analogous to the normal, but less in amplitude. Extension at the knee resulted in the same reflex formula, −+, in the cerebral hemiplegic and the parkinsonian with an amplitude analogous to the reflex movements.—*J. J. Russetzki (transl. by N. Savitsky).*

16414. **RUSSETZKI, J. J. Untersuchungen über den Kniesehnenreflex beim Menschen. III. Über den Kniesehnenreflex bei spinalen Störungen und bei einigen Störungen des Grosshirns.** *Arch. Psychiatr. u. Nervenkrankh.* 89(3/4): 644-669. 1930.—In 15 cases of spinal paraplegia of varied etiology, findings were analogous to those in cerebral hemiplegia. Certain groups of normal subjects (with amplitude of reflex of 16 to 25 degrees) showed at times evidence of functional deficiency of the pyramidal tract similar to those seen in hemiplegics and paraplegics. In 3 cases of tabes dorsalis (initial stage: before the disappearance of the tendon reflexes) posterior movements (pendular type of reflex) were readily elicited. Amyotrophic lateral sclerosis (4 cases) showed a tonic type of patellar reflex concealing the return movement (flexion). Cases with cerebellar lesions showed reflex movements of the pendular type. Chorea was characterized by the marked variability of reflex movements on repeated examinations.—*J. J. Russetzki (transl. by N. Savitsky).*

16415. **SCRIVER, W. de M., and H. OERTEL. Necrotic sequestration of the kidneys in pregnancy.** *Jour. Path. and Bact.* 33(4): 1071-1094. 5 pl. 1930.—In 2 cases following parturition anuria continued for 9 and 5 days respectively; necropsy showed bilateral necrosis of the renal cortex. In a 3rd case, oliguria continued for 6 days but was followed by diuresis and recovery. "These renal vascular disturbances seem to be related to a general abnormal state of vasomotor irritability of pregnancy (hypertension) which locally is functionally and anatomically revealed in the skin and in parenchymatous organs, notably the brain, liver, and kidneys (edema, exudation, hemorrhages, necrosis). From these and similar anatomical observations elsewhere (uremic ulcers, eclamptic livers, spleen and brain lesions) and from experimental evidence as regards irritative circulatory changes in the living warm-blooded animal, it seems that the assumption of a paralytic, terminal, segmentary, circulatory downfall (peristasis, prestasis, stasis) is in better harmony with these findings than the idea of vascular spasm and ischemia. It furnishes, moreover, a more definite mechanical conception of these lesions than the various rather hazy theories of primary toxic cell degenerations."

16416. [SHIPACHEV, V.] ШИПАЧЕВ, В. О зобе в Сибири. [Goiter in Siberia.] [German summary.] Сборник Трудов Иркутского Государственного Университета (*Studies Irkutsk State Univ.*) 17: 61-112. 4 maps, 4 pl. 1930.—Examination of 5211 thyroid patients in various endemic goiter regions of Siberia showed the predominance of the disease among women. Arthritis, arrested bone growth, dryness and desquamation of the skin, mongolism and cretinism were characteristic of the endemic goiter which the author classified as hypothyroidism.

16417. **SHORR, EPHRAIM, ROBERT O. LOEBEL, and HENRY B. RICHARDSON. Tissue metabolism. I. The nature of phlorhizin diabetes.** *Jour. Biol. Chem.* 86(2): 529-549. 1930.—The authors conducted experiments on excised renal and testicular tissues of rats,

studying the effect of phlorhizin on the oxidation of carbohydrates by studying the respiratory quotients by means of Barcroft-Warburg apparatus. The quotients showed that excised tissues utilized food-stuffs in the same proportions as did the intact animal. The excised renal tissue responded to the presence of glucose by an increase in O consumption and a corresponding rise in R.Q. The excised renal and testicular tissue of phlorhizinized rats, with and without phlorhizin in the medium, responded to the presence of glucose in the same way as normal tissue by increases in O consumption and rise of R.Q. Increasing phlorhizin showed no depression of the R.Q.; average of quotients was 0.850, indicating that carbohydrate was furnishing about 50% of the energy. The authors conclude that phlorhizin does not interfere directly with the oxidation of carbohydrate by the cells in general.—*H. J. John.*

16418. **SIKL, H. Über den Lungenkrebs der Bergleute in Joachimstal (Tschechoslowakei).** *Zeitschr. Krebsforsch.* 32(6): 609-613. 1930.—S. reports the results of autopsy findings in 10 miners, with a death rate from pulmonary cancer of at least 50%,—an incidence very close to what has been found in the Schneeberg. The author does not believe that pneumokoniosis is responsible, since this was not especially marked. Chemical analysis of a portion of one of the diseased lungs failed to reveal any agency which could be assumed with probability as the important factor,—of Pb, Bi, As, Co, Ni or uranium there were no traces. Tests for radioactivity were negative, but S. is inclined to suspect that the abundance of radio-emanative material in the mine shafts may be the factor involved.—*H. E. Eggers.*

16419. **SPILLMAN, L., M. VERAIN, et L. J. SEGALL. Considérations sur les variations du déséquilibre acido-basique du sang au cours de la syphilis evolutive.** *Compt. Rend. Soc. Biol.* 106(10): 824-826. 1931.—The pH was determined electrometrically with one hydrogen and one antimony electrode. During secondary syphilis, there is a disturbance in the pH towards alkalinity in most cases (50 observed). Anti-syphilitic treatment diminishes the divergence as it diminishes the positivity of the Bordet-Wassermann reaction. The curve which follows the pH changes under the influence of anti-syphilitic treatment only is parallel to the curves which follow the Bordet-Wassermann and the Kahn reactions.—*E. Weiner.*

16420. **STEARNS, GENEVIEVE, and JULIAN D. BOYD. The healing of rickets coincident with low serum inorganic phosphorus.** *Jour. Clin. Investigation* 10(3): 591-602. 2 fig. 1931.—The clinical healing of late rickets coincident with a persistently low level of serum inorganic P has been observed in 2 children. The retention of Ca and P observed in each child was considered amply sufficient for the building of bone. The data reported do not offer evidence substantiating any of the prevalent theories of bone calcification; moreover, it is difficult to reconcile certain of these theories with the findings.—*Author's summary.*

16421. **STIEFEL, FRITZ. Über einen neuen Abbaureflex bei Delirium tremens.** *Monatsschr. Psychiatr. u. Neurol.* 74(5/6): 369-380. 1930.—In all 5 cases of delirium tremens a rapid dorsal flexion of the foot (football reflex), was elicited shortly after the attack and continued until the final sleep or a few days thereafter; it could not be elicited in any other alcoholic disturbance, in pyramidal or extrapyramidal lesions. The author attributes it to degeneration in the tegmental or suprategmental region.

16422. **STORM van LEEUWEN, W., und P. LARSEN. Über die Atmung der Asthmatiker während leichter Arbeit.** *Zeitschr. Ges. Exp. Med.* 65(3/4): 320-325. 10 fig. 1929.—25 patients and 10 normal individuals were subjected to the slight work of ascending and descending a flight of 18 stairs 7 times. 9 patients were unable to complete the 7 trips because of dyspnea. The alveolar O and CO_2 were determined before the experiment and after each trip. The authors found no essential difference in the alveolar O or CO_2 between the patients and the normal controls. They concluded that the inability of functional emphysematics to carry out work was not dependent on lack of O or excess of CO_2 in the blood.—*H. L. Gruehl.*

16423. **SÜMEGI, ST., und L. FINDEISEN. Über Veränderungen der Rückenmarksflüssigkeit nach dem Tode.** *Frankfurter Zeitschr. Path.* 41(3): 431-434. 1931.—In 50 cadavers with no organic disease of the central nervous system (3 meningitic), spinal fluid was obtained 3-50 hrs. after death. The colloid reactions gave a normal curve until about 9 hrs. after death; later a pronounced left shift in the zone of precipitation. A few hours after death, albumin and rest N had risen considerably. The albumin-globulin quotient was below normal. Sugar disappeared after a few hours; pH shifted toward acid shortly after death.

16424. **[VAKULENKO, I. L., and S. A. ADAMOV.]** ВАКУЛЕНКО, И. Л., и С. А. АДАМОВ. К вопросу о стойкости эритроцитов из крови человека при различных заболеваниях. [**Stability of erythrocytes from human blood in various diseases.**] Известия Томского Государственного Университета (*Trans. Tomsk State Univ.*) 78: 84-93. 1926.—Erythrocyte resistance (E.R.) was tested by Simmel's method on 7 patients with cancer ventriculi, 5 with other gastric diseases, 4 with hepatic diseases, 9 with pulmonary tuberculosis, and 3 with scorbutus, morbus Banti, and endocarditis lenta. Tyrode fluid taken as 1.0, hypotonic solutions of 0.7, 0.6, 0.5, 0.4, 0.3, and sometimes 0.2 were used, which made it possible to distinguish 5-6 groups of erythrocytes in respect to their resistance. In cancer, uterus, and tuberculosis, E.R. was similar. In 0.7 and 0.6 solutions, as a rule, the number of destroyed erythrocytes was within the norm. In 0.5 solution almost always E.R. was normal. Most characteristic for these diseases was the sharp increase in number of erythrocytes resistant to 0.4 solution. In 0.3 solution, however, this number was seldom above normal. In non-cancerous gastric diseases E.R. was different. In 0.5 solution it was often below the norm, while in 0.4 and 0.3 solution it remained normal. In scorbutus and endocarditis erythrocytes with minimal resistance (0.7 and 0.6 solution) decreased sharply.

16425. **VARELA, B., J. DUOMARCO, et A. MUNILLA. Modifications du glutathion réduit du sang et des organes dans l'anémie expérimentale produite par des saignées répétées chez le chien et le lapin.** *Compt. Rend. Soc. Biol.* 106(10): 837-839. 1931.—The blood of 4 dogs and 3 rabbits was studied while the hemoglobin was reduced to 50% of its original value by bleeding. After a varying period, the animal was killed and the amount of glutathione in the liver, kidneys, spleen and myocardium was determined by a modification of the method of Tunicliffe and Dixon. In the dog, the glutathione of the corpuscles and that in the tissues is increased, the latter increasing with increasing anemia. In the rabbit, this increase is still greater. As the number of red cells decreases, their glutathione increases.—*E. Weiner.*

16426. **VOGT-MØLLER, P. Ist Avitaminosis B_1 eine Intoxikation mit Methylglyoxal?** *Biochem. Zeitschr.* 233 (4/6): 248-250. 1931.—In a preliminary report the author suggests that the signs of avitaminosis B_1 intoxication (A.B_1 I.) are caused partly or entirely by methylglyoxal. He was able to demonstrate its presence in A.B_1 I., but not in liver-ferment system plus hexosephosphate of fasting or normal mice. Methylglyoxal intoxication resembles experimental beri-beri in many ways.

16427. **WITTMAACK, K. Über Schallschädigung durch Knochenleitung.** *Arch. Ohren-, Nasen- u. Kehlkopfheilk.* 123(1/2): 49-62. 1929.—The author's reply to criticisms of his work on the injury of the inner ear through bone conduction, with a report of additional experiments in which it was found that control mice exposed to certain sound waves received only by air conduction showed no demonstrable changes in the inner ear, while others receiving the same sound waves both by air conduction and bone conduction developed changes previously de-

scribed by the author as characteristic, in location and nature, of injury resulting by bone conduction.—*J. B. Youmans.*

16428. [ZHODZISHSKIĬ, B. IA.] ЖОДЗИШСКИЙ, Б. Я. К вопросу о влиянии рапных и грязевых ванн на креатининовый обмен у ревматиков. [Effect of saline and mud baths on creatinin metabolism in rheumatics.] Известия Томского Государственного Университета (*Trans. Tomsk State Univ.*) 78: 283-303. 1926.—Experiments were made on 30 patients. Creatinine content in the urine of chronic rheumatics was only ¼ or ⅓ that in normal subjects. After 8-10 saline baths, 30% to 50% increase of creatinine in urine was observed. After 10-12 mud baths the increase was 100 to 150%.

16429. **ADAMSTONE, F. B. The effects of vitamin-E deficiency on the development of the chick.** *Jour. Morph. and Physiol.* 52(1): 47-80. 4 pl., 1 fig. 1931.—In an investigation of the hatchability of eggs from hens fed on a diet deficient in vitamin E, Card found that all embryos from these eggs died during development. Study of these chicks showed that a variety of conditions were responsible: During early development the rate of growth and differentiation was definitely slower than under normal conditions, but malformations were rare. Some embryos died during the first 2 days, due to disintegration of the circulatory system or its failure to become established. At the end of the 4th day there was a definite critical period which few specimens survived, and by this time distinct pathological conditions had arisen in extra-embryonic structures. These involved wiping out of the vitelline circulation by establishment of a lethal ring in the blastoderm. This structure was produced by intensive cell proliferation in the mesoderm, which resulted in choking out vitelline blood vessels and in their subsequent degeneration. It also caused obliteration of the exocoele, with consequent failure of the allantois to expand. In addition, many embryos showed profuse hemorrhage into the exocoele. The source of bleeding was most frequently in the atrium of the heart, and at actual rupture peculiar cells occurred, which were probably histiocytic mesenchyme cells. Although death was due directly to causes enumerated above, the ultimate responsibility rests on conditions set up by them, viz.: starvation, asphyxiation, and loss of the medium (blood) by which to carry on metabolic exchange.—*Author (courtesy Wistar Bibl. Serv.).*

16430. **ALEKSA, K. Raguočiu tuberkulĩozo klausĩmu anketos davinĩai. [Cattle tuberculosis in Lithuania.]** *Žemės Ūkio Akad. Metraštis [Lithuania]* 1929/1930: 156-174. 1931.—According to special investigation made in 1930, there is in Lithuania no well-planned control of cattle tuberculosis. Registration of infected animals as now done is far from perfect. The number of infected cattle probably does not exceed 5%. The number of infected pigs continually increases.—*K. Aleksa.*

16431. **BAKER, S. L. Transplantation of a teratomatous ovarian tumour in the fowl. Production of a sex hormone by the cells of the transplants.** *Lancet* 220(5614): 742-751. 5 fig. 1931.—A teratomatous tumor of the ovary in fowls was successfully transplanted to the 1st generation of hosts. The predominating cells in the original tumor and in the transplants resembled those in the theca interna of the ovarian follicles; lipoid-containing cells were a prominent feature. In addition, there were sparsely scattered groups of columnar-celled tubules and keratinizing epithelial masses. The original tumor-bearing fowl showed a fully developed oviduct but an undeveloped immature ovary. Young birds bearing tumor transplants showed a precocious development of the oviduct, the cloacal orifice of which became perforate. The ovaries of these birds remained immature.—*Author's summary.*

16432. **BENNETT, GRANVILLE A., and WALTER BAUER. A systematic study of the degeneration of articular cartilage in bovine joints.** *Amer. Jour. Path.* 7(4): 399-414. 24 fig. 1931.—Constant differences in the synovial fluid of the carpometacarpal and astragalotibial articulations of cows were described previously. The finding of areas of degeneration in the articular cartilages of the carpometacarpal articulations of all cattle over 2 yrs. old would appear to be an adequate explanation of the synovial fluid differences observed. These areas of progressive degeneration have been studied systematically. Development of the carpometacarpal articulations was studied in bovine embryos and calves. The vascular articular cartilages of embryos and calves became avascular before the animals were 2 yrs. old. Pronounced rearrangement of the subchondral bone trabeculae resulted in a relatively deficient bony support of the medial articular cartilage where the degenerative lesions occur. Such cartilage lesions are probably due to repeated trauma in weakly constructed articulations, with deficient subchondral bone support as an important predisposing factor. The type of cartilage lesion described is not wholly similar to any of the joint lesions described in human arthritis.—*Author's summary.*

16433. **BLOUNT, W. P. Urinary calculi.** *Vet. Jour.* 87(12): 561-575. 1931.—A general summary of urinary calculi as seen in domestic animals.—*I. E. Newsom.*

16434. **BURNSIDE, C. E. Fungous diseases of the honeybee.** *U. S. Dept. Agric. Tech. Bull.* 149. 1-43. 6 pl., 5 fig. 1930.—Honeybees, both larval and adult, are attacked by certain fungi; those used in these studies were collected from widely scattered apiaries. The fungi most frequently observed are of the green and blue mold groups. The blue molds tested (*Penicillium* spp.) are apparently incapable of parasitism in nature, their growth is saprophytic on or in the bodies of bees after death. The green molds in particular caused death of bees, following artificial feeding. Several members of the genus *Aspergillus* including *flavus* (series), *fumigatus, nidulans, niger, glaucus,* and *ochraceus* were found injurious. Alcohol, ether and chloroform extracts from the media employed in culturing these organisms were nontoxic; the formulas of media used are given. None of the black molds (*Mucors*) attacked bees, except *M. hiemalis,* under certain conditions. Several other filamentous fungi tested also gave negative pathogenic results. Yeasts (*Saccharomyces ellipsoideus* and *S. cerevisiae* in particular) caused but slight dysentery when fed wholesale. The yeasts, however, produced death after inoculation into the blood. No outward abnormal symptoms were discernible in the dead bees.—*G. H. Vansell.*

16435. **CASH, J. R., and C. A. DOAN. Spontaneous and experimental infection of pigeons with B. aertrycke.** *Amer. Jour. Path.* 7(4): 373-398. 22 fig. (14 col.) 1931. —The apparently spontaneous development of a fatal disease in undernourished pigeons is reported. It is characterized by anemia, marked myeloid hyperplasia of bone marrow, striking increase of myeloid elements of blood, and extensive infiltration of liver and kidneys

with myeloid tissue. In addition, large, nodular, often necrotic masses of mononuclear phagocytic cells are frequently scattered throughout liver, spleen, kidneys, and bone marrow. *B. aertrycke* was regularly recovered in pure culture from blood, liver, kidney, spleen and bone marrow. The bacteria occur in the foci of mononuclear cells, not within the collections of myelocytes. The disease has been produced experimentally in normal pigeons by intraperitoneal injection of liver emulsion from naturally infected birds, intraperitoneal injection of *B. aertrycke* from the same source, and by oral administration of single large doses of broth cultures. Bacteria-free filtrates of broth cultures had no demonstrable effect on normal pigeons when injected or administered orally in single large doses. Frequently pathological changes occur in the tissues of apparently normal birds. —*Author's summary.*

16436. **CASTRO, A. MARTINS de. Tinhas dos animaes domesticos em São Paulo. Microsporia: Microsporon felineum C. Fox e F. Blaxall, 1896, e Microsporon canis Bodin-Almy, 1897 = Microsporon lanosum Sabouraud, 1907.** [Tinea in domestic animals of São Paulo.] *Arch. Inst. Biol. [São Paulo]* 1: 201-216. 7 pl. 1928.—In studying cutaneous mycoses, foreign and local types of tinea in animals were considered. Clinical, microscopic, and cultural examinations were made on Brazilian domestic animals. The findings were correlated with those in 320 case of human tinea. *Microsporon felineum, M. lanosum, Trichophyton gypseum asteroides* and *T. granulosum* are regarded as of undoubted animal origin; and *T. lacticolor, T. rosaceum* and *T. cerebriforme,* of probable animal origin. Tinea is by far more common in man at São Paulo than Microsporiae, and the cases are generally of *M. felineum* infection. Microsporia produced by *M. felineum* were observed in 5 cats and in 1 dog; 1 case of *M. lanosum* infection was seen in a dog. —*B. Bickel.*

16437. **GIRARD, G. Immunité du hérisson et du tanrec à la peste expérimentale.** *Compt. Rend. Soc. Biol.* 106 (12): 1078-1080. 1931.—Hedgehogs (*Ericulus setosus*) and tenrecs (*Centetes ecaudatus*) when artificially infected with cultures of the plague bacillus or tissues containing the organism, failed to develop the disease or to carry the organism. From these observations the author concludes that these animals are not reservoirs of plague infection.—*From abstract by E. Weiner.*

16438. **HABACHER, F. Beiträge zum sogenannten Hufkrebs.** *Wiener Tierärztl. Monatsschr.* 18 (14/16): 417-432. 2 pl., 4 fig. 1931.—In this study of canker and dermatitis of the hoof and fetlock regions in horses, the following conditions were noted: papilloma, condyloma, fibroma, atonic ulcer, pododermatitis, and chronic eczematose dermatitis. Histologic sections revealed streptococci, staphylococci, *B. necrophorus, B. coli* and various spirochaetes in the lesions. The rôle played by these microorganisms in the various diseased conditions was not determined. Histopathological studies showed that each disease was progressive and produced inflammatory, hypertrophic and hyperplasic effects on various tissues of the hoof and fetlock regions.—*C. S. Gibbs.*

16439. **HADLEY, F. B. Streptococcus epidemicus infection in the cow and its relation to milk-borne infections in man.** *North Amer. Vet.* 12 (9): 29-31. 1931.—*Strep. epidemicus* belongs to the β-hemolytic group and reveals a well-marked capsule with India ink. It can be positively identified only by bacteriologic methods. Spontaneous cases of infection are not uncommon in cows, from the milk of which *Strep. epidemicus* can be recovered. An epidemic in which 250 persons were affected, 5 of which died, was traced to 1 cow and proved to be milk-borne. Certain cows exposed at the teat orifices to strains of the organism of both bovine and human origin developed mastitis within 48 hrs. Chronic infections usually end in permanent destruction of function in involved quarters; temporary infections are apparently caused by less virulent strains or result from individual immunity.—*F. B. Hadley.*

16440. **HAGER, G. Zur Frage der Ursache der Dürener Rinderkrankheit.** *Fortschr. Landwirtschaft* 2 (11): 360-362. 1927.—It has recently been shown by Bleyer and Mayer that rats fed on a vitamin-free diet would not gain in weight when an extracted soy bean meal was added to the regimen, as they would when unextracted meal was used or when extracted meal to which the fat had been restored, was added. Meal extracted with benzine or with trichlorethylene proved deficient. The author warns that these results should not lead to the assumption that Dürener cattle disease results from vitamin deficiency. He points out that it has occurred on a variety of rations, usually adequate in themselves, but always when soy bean meal from which the fat had been extracted, was fed. He emphasizes particularly the fact that the disease has not occurred when soy bean meal has been extracted with benzine, but always when done with trichlorethylene. He concludes that the disease results from poisoning by an unknown product left in the defatted meal after extraction with trichlorethylene.—*W. A. Hagan.*

16441. **HALLMAN, E. T., L. B. SHOLL, and A. L. DELEZ. Observations on the pathology of Bacterium abortus infections.** *Michigan Agric. Exp. Sta. Tech. Bull.* 93. 1-19. 17 pl. 1928.—Lesions associated with *Bact. abortus* infection in experimentally infected guinea pigs, in naturally infected fetal membranes and udders of cows, and in aborted calves are discussed. Human, porcine and bovine strains of the organism were used. The primary lesion in guinea pigs consists of reticulo-endothelial cells, small round cells and fibroblasts. Necrosis may or may not occur, followed in some instances by abscessation. Studies of *Bact. abortus*-infected fetal membranes indicate that necrotic placentitis and necrotic chorionitis are the predominating lesions of bovine fetal membranes. Extensive necrosis of the placenta, per se, is thought to have no influence on development of placental areas during subsequent pregnancies. Fetal pneumonia is a frequent condition in aborted calves and may have some relation to calf pneumonia. Histological studies of the bovine udder indicate that *Bact. abortus* infection is associated with subacute or chronic interstitial mastitis, with some degeneration of the parenchyma and with some exudation into the acini in more acute processes.—*E. T. Hallman.*

16442. **HAYDEN, C. E. Sugar, guanidine, and cholesterol in the blood of the cow in milk fever.** *Rept. New York State Vet. Coll. Cornell Univ.* 1928/1929: 143-152. 1930.—By Benedict's method the sugar content of normal milk cows was determined to average 41.15 mgm. per 100 cc. of blood. Samples from cases of milk fever before udder inflation gave a glucose average of 63.19 mgm. The test for guanidine bases gave an average higher after inflation than before. The average cholesterol readings for the period before inflation were lower than those of normal milk cows. On recovery, the cholesterol readings were slightly lower than those of samples before inflation.—*F. Volkmar.*

16443. **HEELSBERGEN, T. von. Infectiöse Cloacitis bei Hühnern.** *Deutsche Tierärztl. Wochenschr.* 39 (18): 274-275. 1931.—Dissemination of cloacitis occurs only when a rooster runs with diseased and healthy hens, but the male in such cases is not regarded as merely a mechanical carrier. A rooster placed in the pen with healthy hens infected them. The circumstance that the male had for some time been associated with pullorum-diseased hens suggested the possibility that *S. pullorum* was involved; but it was not demonstrated. The etiology of the disease remains obscure.—*H. Bunyea.*

16444. **HENDERSON, WILLIAM. The relationship of pica in cattle to trypanosomiasis.** *Vet. Jour.* [*London*] 87 (11): 518-529. 1931.—It is concluded that: Pica in Northern Nigeria bears a close relationship to trypanosomiasis of cattle. Infection by trypanosomes causes an acidosis, with consequent upset of the "alkali reserve" of the blood. Excessive excretion of Na and Ca during an acidosis can not be compensated for by the amount of these elements in the herbage normally grazed. The uncompensated loss of Na and Ca leads to a craving

for salts containing these elements, and it is expressed by the showing of pica symptoms.—*I. E. Newsom.*

16446. **JACOTOT, H. La pasteurellose des boeufs et des buffles en Indochine.** [Pasteurellosis of cattle and buffaloes in Indo-China.] *Arch. Inst. Pasteur Indochine* 5/6. 5-92. 1 fig. 1927.

16447. **JÜRGENS, AXEL. On the mutual relation of calf diplococci and pneumococci.** *Acta Pathol. et Microbiol. Scandinavica Suppl.* 3: 199-208. 1930.—Certain diplococci (calf diplococci) causing in calves a septicemia accompanied by special pathological changes in the spleen and intestinal canal were closely related to pneumococci. By simple agglutination, some of the calf-diplococcus cultures and their sera proved completely identical with pneumococci types I and II and their sera, but no strain was identical with type III. Agglutination with absorption showed complete agreement with simple agglutination. The fermentation character of the calf diplococci was the same as that of the pneumococci. Protective tests carried out on mice revealed no dissimilarities between the calf strains falling into the human type I and II groups and the human types I and II.—*A. Jürgens.*

16448. **KADLETZ, MAXIMILIAN. Ist der Spat des Pferdes mit dem Plattfusse des Menschen grundsätzlich** vergleichbar? *Münchener Tierärztl. Wochenschr.* 82(16): 189-193. 2 fig. 1931.—From musculature and morphological studies it is concluded that equine spavins and human flat-foot are homologous diseases and should yield to similar treatments.—*From abstract by M. Kadletz (transl.).*

16449. **LINTON, R. G. Transit fever.** *Scottish Jour. Agric.* 14(4): 391-401. 1931.—The writer calls attention to this serious disease of cattle shipped by steamer to England and Scotland. The advisability of investigating its nature is considered.—*From abstract by R. G. Linton.*

16450. **McCARRISON, ROBERT. A goitre survey in albino rats.** *Brit. Med. Jour.* 1(3621): 989-992. 1 fig. 1930.—A survey was made of 2,651 rats in a locality (Coonoor) where goiter is not endemic; 148 were found at post-mortem examination to have goiter. Temp. conditions of spring and summer months in Coonoor appeared more favorable to development of goiters than those of the colder months. Incidence of goiter was higher in ♀♀ than in ♂♂. Goiter was most frequent in rats at the age of sexual maturity. Associated diseases did not appear to have exercised appreciable influence on goiter incidence. The goiters are not due to endemic influences. The rats had no hereditary predisposition, nor were they subjected to insanitary conditions. Well-fed rats (393), living under sanitary conditions, did not develop goiter; but 6.8% of ill-fed rats (2,168) living under sanitary conditions had goiter. Faulty food, deficient in vitamins, was the cause of the goiters. Administration of iodine to deficiently-fed rats was definitely favorable to goiter production; its administration to rats fed on physiologically complete diets was not. Urinary excretion of iodine by rats fed on deficient diets with composition favorable to goiter production, was in some experiments as low as 33 γ per liter and in others as high as 200,000 γ per liter. The histological appearances of 79 of the 148 goiters are briefly described; 44.3% were lymphadenoid, 25.3% were hypertrophic, and others intermediate, goiters. Based on their findings and the work of others it is concluded that standards of normal thyroid weights for albino rats in one part of the world may not be applicable to those in another part.—*Author's summary.*

16451. **MAKKAWEJSKY, W. N., J. A. KARKADINOWSKY, und N. J. MICHEJEW. Über die Ansteckung der Meerschweinchen und Kaninchen mit Brucella-melitensis-abortus durch die unverletzte Haut.** *Deutsche Tierärztl. Wochenschr.* 39(33): 518-519. 1931.—25% of a series of guinea pigs and 60% of rabbits infected with *Br. abortus* through the unbroken skin gave positive agglutination reactions. With *Br. melitensis*, 10% of the guinea pigs and 20% of the rabbits reacted. 60% of the guinea pigs and 90% of the rabbits reacted following conjunctival introduction of these bacteria.—*Authors' conclusions (transl. by J. B. Nelson).*

16452. **MAYER, MARTIN, WERNER BORCHARDT, und WALTER KIKUTH. Die durch Milzexstirpation auslösbare infektiöse Rattenanämie.** [Infectious rat anemia dispelled by splenectomy.] *Arch. Schiffs- u. Tropen-Hyg.* 31(Beih. 4): 5-27. 3 pl. 1927.

16453. **MEDLAR, E. M. Avian tuberculosis in normal and vaccinated rabbits.** *Amer. Jour. Path.* 7(5): 475-490. 5 pl. 1931.—Comparison of 8 non-vaccinated and 4 vaccinated rabbits intravenously inoculated with virulent avian tubercle bacilli showed a significant difference, not merely in length of life and in presence and extent of lesions, but also in gross- and histopathology and in leucocytic response. Tubercle bacilli were more numerous in the non-vaccinated, but typical tubercles (representing a regressive phase of infection and increased resistance of host) were common in vaccinated animals but not seen in non-vaccinated animals dying in 3-4 wks. The leucocytic response in vaccinated rabbits gradually became that of a septic reaction, closely resembling that in human progressive tuberculosis; it is attributed to the damaged tissue in the lesions. The megakaryocyte played an important part, of as yet unknown significance, in these acute infections with avian tuberculosis.

16454. **MINETT, F. C., and A. W. STABLEFORTH. Studies on bovine mastitis. IV. The occurrence in mastitis of haemolytic streptococci showing group similarity to Streptococcus pyogenes of man.** *Jour. Comp. Path. & Therap.* 44(2): 114-125. 1931.—In a series of 113 cases of mastitis, previously reported and unselected except that they were showing pronounced clinical symptoms, 52 were found due to beta-hemolytic streptococci. In 39 they were of the kind commonly met with in mastitis; in the remaining 13, they were distinct from the usual udder streptococci and indistinguishable as a group, by bacteriological and serological tests, from *Strep. pyogenes* of direct human origin. The evidence therefore strongly suggests, though it can not be held to prove, that in these cases the streptococci had been implanted in the udder by the milker. In 7 of the 13 cases, the organisms were present in large and predominating numbers, indicating that they were the cause of the mastitis. Notable features of these strains were their strong hemolytic properties and their high virulence for mice and rabbits. One strain produced small amounts of soluble toxin. In the more severe cases of streptococcus mastitis, strains with the characters described do not appear to be uncommon. Inquiry of the veterinary surgeons in attendance elicited the following information: All except 4 cases occurred on different farms and in widely separated districts. All the cows had been milked by hand and most of them had recently calved. There was no definite history of illness among the milkers or other persons in contact.—*F. C. Minett.*

16455. **MIRONE, GIUSEPPE. Présence de corpuscules endoglobulaires dans le sang des lézards.** *Ann. Inst. Pasteur [Paris]* 45(2): 243-246. 1 col. fig. 1930.—In 6 of 102 specimens of Piedmont lizards, (*Lacerta muralis, L. vivipara, L. viridis*), the author found numerous rounded, refractive, immobile, finely granular, intracellular bodies, 1.5-3 μ in diam., paranuclear and near the periphery of the erythrocyte. Such bodies free in the plasma of the circulating blood have not been found. The nature of these inclusion bodies is in doubt, but they are not regarded as products of karyolysis produced by hemogregarines, since only 6 lizards presented them, while practically all of the 102 were infected with hemogregarines. The inclusion bodies in the 6 individuals occurred in about 85% of the erythrocytes, and those erythrocytes never contained the *Karyolysus* (hemogregarine).

16456. **MOODIE, ROY L. Studies in paleopathology. XXVIII. The phenomenon of sacralization in the Pleistocene sabre-tooth.** *Amer. Jour. Surg.* 10(3): 587-589. 2 fig.

1930.—This phenomenon, apparently never previously described in any animal other than man, was observed in 5 of 1034 specimens of the sacrum of the sabre-tooth tiger (*Smilodon californicus*) of the Rancho la Brea preserved in the Los Angeles Museum.

16457. NIEBERLE, KARL, und PAUL COHRS. Lehrbuch der speziellen pathologischen Anatomie der Haustiere. [Textbook on pathologic anatomy of domestic animals.] iv+796p. 556 fig. (some col.) Gustav Fischer: Jena, 1931.

16458. NORWIG, HANS GEORG. Zur Pathologie der Genitalorgane des weiblichen Schweines u. Hundes mit besonderer Berücksichtigung der Histologie des Eileiters. [Pathology of the genital organs in female pigs and dogs, with especial reference to the histology of the Fallopian tube.] 50p. Thesis: Univ. of Leipzig, 1929.

16459. SPIES, TOM DOUGLAS, and THOMAS TIPTON WALKER. A comparison of the effects of viosterol in acute experimental avian and bovine tuberculosis. *Amer. Rev. Tubere.* 24(6): 723-728. 1931.—To determine whether the difference in calcification (spontaneous in one, practically absent in the other) between bovine and avian tuberculosis is due to a difference in the bacteria or in the host, the calcifying effect of large doses of viosterol was observed in 8 of 12 guinea pigs infected with acute avian tuberculosis. In these guinea pigs, in contrast to results previously observed in acute bovine tuberculosis, there was little or no calcification either of the lesions or of the heart, liver and kidney parenchyma—possibly because of (1) fundamental difference in toxicity of the 2 bacterial strains; (2) greater generalized non-specific toxicity of the bovine type; or (3) greater emaciation and susceptibility to hypervitaminosis in the bovine-infected animals.

16460. THOMAS, J. ANDRÉ. Étude d'un processus néoplastique chez Nereis diversicolor O.F.M. dû à la dégénérescence des oocytes et quelquefois des soies. *Arch. Anat. Microscop.* [*Paris*] 26(2): 251-333. 2 pl. (1 col.), 20 fig. 1930.—*N. diversicolor* of the Roscoff region are infested with tumors, sometimes voluminous and multiple, originating at the expense of the parapodia and the setigerous somites. These tumors are due to irritation set up by the degeneration of oocytes and sometimes by setae which, moreover, are fragmented and phagocytosed. The oocytes are invaded by a chromolipoid pigment, the cytoplasmic constituents disappear, there are pyknosis and karyorrhexis accompanied by passage of chromatin into the cytoplasm, a process hitherto known only in vertebrates. The setae are invaded by the same pigment as that of the oocyte but are resistant to penetration of paraffin. This setal degeneration should perhaps be regarded as the beginning of epitoke. Leucocytes flow around the oocytes or degenerate setae. They pass into the phagocyte phase and form around the inclusion a plasmodial layer which, in its turn, degenerates centrifugally. An active process of lymphogenesis appears in the tumors, starting from the coelomic epithelium and especially from the covering of the vessels, ending in the formation of lymph nodes which become free in the parenchyma. These nodes give rise to 2 distinct cellular lines, starting from the hyalin leukocytes of Kollman's stage I: the linocytic line, where one can trace the appearance of the linome without there ever being any granulations or fatty inclusions; and the adipose granular line, less abundant, leading to formation either of elecocytes, or granulocytes which have their granulations from stage I. This mass of free elements (amoebocytes) flows around the reacting nodes. The linocytes elongate, become giant (100μ), the linome forms in the cell a single, long, sinuous axis, and the cytoplasm becomes less and less important. There is organization of a newly formed, very peculiar, even fibroblastic connective tissue, by coalescence of these elements of the quiescent type. The fibrillae of this tissue,—long, flexible, and parallel with it,—derive directly from the linome of the giant linocytes. Attempts to isolate microorganisms as the etiologic factors in the tumor production were negative. An analogous and more or less permanent mechanism may be produced experimentally by injection of a powdered tumor in absence of all microbic action, or sometimes by simple lesion with a sterilized needle.—*J. A. Thomas* (*transl. by A. L. Treadwell*).

16461. THOMSEN, AXEL. Om Kalvekastningsfeberens (Svingefeberens) Forekomst hos danske Dyrlaeger. [Undulant fever among Danish veterinarians.] *Maanedsskr. Dyrlaeger* 43(2): 46-56. 1931.—Up to April, 1931, undulant fever had been diagnosed in 6 instances among veterinarians in Denmark. All 6 became ill shortly after they began practicing in abortus-infected stables. Older veterinarians do not usually contract the disease, 94% of those who have practiced for more than 1 yr. having specific antibodies against *B. abortus*. The author thinks that undulant fever was unknown in Denmark prior to 1925.—*A. F. Reith.*

16462. TOBBACK, L. Le charbon bactéridien au Katanga. [Anthrax in Katanga.] *Bull. Agric. Congo Belge* 21(2): 489-494. 1930.

16463. TSCHERNIAK, W. S., und N. A. ROMANOV. Die multiplen Kalkablagerungen in den Geweben des Organismus der Hunde bei der sogenannten "Stuttgarter Hundeseuche." *Arch. Wiss. u. Prakt. Tierheilk.* 63(5): 436-458. 10 fig. 1931.—Calcification occurred in the endocardium, myocardium, blood vessel walls, kidneys, mucosa of the upper air passages, stomach, uterus, serous membranes, skeletal muscle, lung, and skin. Calcification of the endocardium of the left atrium was demonstrated in all cases. The connective tissues were particularly subject to calcification. An altered Ca metabolism is indicated.—*J. B. Nelson* (*from authors' summary*).

16464. WEBER, und GIFFEY. Beitrag zur Wild- und Rinderseuche. *Miessner-Festschrift* p. 207-217. Fritz Eberlein: Hannover, 1930.—By subcutaneous injections with cultures or material from hemorrhagic septicemia, it could be reproduced in rabbits, mice, sparrows, starlings, crows, doves, guinea pigs, and rats. Transfer from animal to animal or by placing in the undisinfected cage was unsuccessful. Guinea pigs, mice, and starlings could be infected with contaminated feed. Immunity was not produced by feeding with infected material. Animals of the same kind varied in resistance. The causative agent of the disease is very resistant to decay; only after exposure for 12 days is the virulence reduced.—*From authors' summary* (*transl.*).

GENERAL

16465. AKSJANZEW, M. I., und A. N. KREWER. Versuch einer pathologisch-anatomischen Charakteristik der Generalisation des Tuberkulosevirus bei verschiedenen Infektionsverfahren. (Zur Frage der experimentellen Begründung der hämatogen-disseminierten Formen der Lungentuberkulose.) *Zeitschr. Tuberk.* 61(3/4): 251-256. 4 fig. 1931.—Rabbits (29) vaccinated with 2 subcutaneous injections each of 10 mgm. of BCG, were then, with 13 controls, divided into 3 series and inoculated 40 days later with 1 mgm. of the Vallee strain (highly toxic, bovine type): (1) into marginal vein of ear; (2) sub-

cutaneously; (3) intratracheally. All animals died in 17-120 days. In the controls, intravenous and subcutaneous inoculation produced widely disseminated tuberculosis, as did most of the 7 intratracheal inoculations. In the vaccinated, infection was sharply delimited to site of injection. The fibrous, productive, exudative, and caseous reactions were conditioned by the vaccination. Extensive caseation appeared in the vaccinated animals, as well as in the others, and a marked fibrous reaction there only; the capsulation of foci and tendency to delimitation of the processes were pronounced.

16466. **ALEXEIEFF, A. Sur les cellules à poussières du poumon et les "Herzfehlerzellen." Introduction au problème de l'immunité.** *Centralbl. Bakt. I. Abt. Orig.* 103(6/8): 390-415. 1 pl., 2 fig. 1927.—The author insists on a triple nomenclature, corresponding to their triple function, for cells containing dust particles, found in sputa not only of persons with cardiac defects or bronchitis, but also of healthy elderly persons. He calls them "coniophages," because of their dust-scavenging function; "erythrophages" or "Herzfehlerzellen," because they also dispose of the erythrocytes from extravasated blood; and "lipophages," because he believes them to be concerned in fat metabolism. The nucleus in these cells is always eccentrically placed and generally possesses a nucleolus; the cells, exceedingly mobile and changeable in shape, he calls "mesenchymatous amebocytes." Following Roget, he assigns to the lungs an active rôle in elaboration of fats through the lipophages, which constitute in their ensemble a kind of "lipogenic and lipolytic gland" of the lung. Further, he regards each amebocyte as a kind of unicellular gland, secreting both oxidizing and reducing ferments. Their wide distribution enables them to regulate metabolism within the tissues. Immunity is effected primarily by digestion of the lipoids rather than of the proteins of the invading organism. The metabolism of fats takes place in the lymphatic system; hence, the reticulo-endothelia of the various organs may be considered as islands of lymphatic tissue intercalated in the parenchyma of these organs, and the joint lymphatic-reticulo-endothelial system forms a macrophagal system, the theory of which is expounded at length.

16467. **[ALISOV, P. A., and A. N. EGOROV.]** АЛИСОВ, П. А., и А. Н. ЕГОРОВ. К вопросу о предупреждении беременности путем подкожного введения сперматозоидов. **[Prevention of pregnancy by subcutaneous sperm injections.]** [With German summary.] Журнал Экспериментальной Биологии и Медицины (*Jour. Biol. et Méd. Exp.*) 8(20): 247-259. 1927.—Experiments were conducted on 18 ♀ guinea pigs and 10 ♀ rabbits; into the former, 300 millions, into the latter 900 millions, of living homogeneous sperms were injected 4 times at weekly intervals. Ox sperms (alive and killed by chloroform) were injected into guinea pigs in quantities of 490-610 millions; into rabbits, 3.7-3.9 milliards. Neither sterilization nor definite retardation of pregnancy was achieved.

16468. **ARTHUS, ANDRÉ. Immunisations par de minuscules quantités d'anacobra.** *Compt. Rend. Soc. Biol.* 106(12): 1123-1124. 1931.—8 rabbits received subcutaneous injections of anacobra (cobra venom treated with formol and glycerin and kept at 38° C. for 1 mo.) diluted with saline. The immunity produced increased as the quantity of antigen injected decreased, confirming the results of M. Arthus on venom and anavenom. Immunity did not increase with increasing number of injections, the 8 preparatory injections giving a value which is maintained if the succeeding injections are the same in concentration and quantity. A supplementary injection, larger than the previous ones, raised the immunity above this level, in 3 rabbits.—*E. Weiner.*

16469. **ASSIS, ARLINDO de. Sobre a technica do preparo da vaccina B.C.G.** [With English summary.] *Brasil-Med.* 45(15): 338-341. 3 fig. 1931.—Technical notes on the preparation of BCG oral vaccine as used in Rio-de-Janeiro for prevention of tuberculosis in newborn. Aside from the simplified technique recently devised at the Institut Pasteur of Paris for counting the bacilli, a certain number of practical modifications have been described, such as neutralization of Sauton's medium in presence of phenolphthalein, instead of an accurate determination of pH; and storage in vials, instead of in ampules. It is to be noted that 6 cgm. of living BCG bacilli have been administered for the past 2 yrs. as a routine dose for the whole vaccination, instead of the French practice of only 3 cgm.—*A. de Assis.*

16470. **AUCLAIR, JULES. Vaccination préventive et curative du cobaye et du lapin contre la tuberculose humaine. Les indications chez l'homme.** 184p. Masson et Cie: Paris, 1930. Price 25 fr.—This book is divided into 3 parts: the 1st deals with prophylactic vaccination of guinea pigs and rabbits against human tuberculosis; the 2nd with curative vaccination of guinea pigs and rabbits against tuberculosis, and the 3rd with vaccination of man against tuberculosis. The author's criterion of successful vaccination of guinea pigs was the production of a totally refractory state to injection of tubercle bacilli fatal for unvaccinated controls. He seems to have approached success in some of the experiments. Vaccinated guinea pigs and rabbits, previously infected with tubercle bacilli, showed regression of lesions and recovered. In man with lupus and other forms of cutaneous tuberculosis, the conditions showed great improvement. More extended observation is required to determine the outcome of this treatment in other forms of tuberculosis in man. The vaccine is not clearly described; it is apparently composed of killed tubercle bacilli treated with an extract of the pancreas of chickens.—*S. Bayne-Jones.*

16471. **BAUTZ, TH. Über Hautinfektion und Hautvakzination bei Anthrax. II.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 61(1/2): 115-121. 1929.—The authors used a single spore strain of *B. anthracis* of fixed virulence, and Zenkowsky's spore vaccine. A dose of 0.5-2.0 cc. of the vaccine or 0.2-2.0 cc. of the virus was rubbed 0.5-1 min. on the freshly shaved, lightly scarified guinea pig's abdomen. The subcutaneous dose of Vaccine II was 0.05-0.3 cc.; of the virus, 0.05-0.1 cc. The dosage was increased gradually at intervals of 8-20 days. After Vaccine I, Vaccine II was used, and then the virus. In the longest experiments, 13 applications were given during 6 mo. 5 skin applications of vaccine made guinea pigs resistant to skin infection with virus, but not to subcutaneous injections of Vaccine II or virus. 5 applications of vaccine plus 8 of virus protected against subcutaneous virus. Therefore, guinea pig skin is relatively resistant to anthrax and immunization against skin infection is proportionately easy. Immunization against subcutaneous infection is much more difficult. Besredka's theory of elective sensitiveness of the skin to anthrax is untenable. Immunity to anthrax is general, not local.—*L. H. Cady.*

16472. **[BERLIN, A. L.]** БЕРЛИН, А. Л. К вопросу о значении реакции термопреципитации в практике обследования чумных эпизоотий. **[Significance of thermo-precipitation reaction in investigation of plague epizootics.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 54-59; German summary, 129. 1930.—During the plague epizootic of marmots in Kazakstan in 1929, 55 marmots were studied by the thermo-precipitation reaction. As the precipitating serum, anti-plague serum prepared by the Paris method from immunized horses was used. This serum had high precipitating properties with extracts of plague bacillus and organs of animals dying from experimental plague, but gave no turbidity either with physiological saline or with extracts of normal organs of guinea pigs or rats. The spleen, liver and, rarely, pieces of lung and lymphatic glands of marmots suspected in post mortems of having plague, were examined by this reaction. The organs were ground, at first without, and later with, addition of NaCl solution; filtration followed after heating in a water bath

for 5 min.; 0.5 cc. of these extracts was added to vials containing 0.5 cc. of precipitated serum. In case of positive reaction, turbidity was noted immediately. Among the 55 animals studied, in 6 cases plague was established by patho-anatomical and bacteriological studies, and by the thermo-precipitation reaction in 5 cases (83.3%). Of 49 negative cases, the thermo-precipitation reaction was negative in 43 cases, and positive in 6 (12.2%); thus the thermo-precipitation reaction may give positive results in negative cases, which lessens its value as an auxiliary method for diagnosing plague.—*G. A. Lebedeff.*

16473. BERTHELSEN, KNUD C. A study of the relationship of surface phenomena to the reaction of toxin and antitoxin, with toxin produced in an infusion-free peptone medium. *Jour. Immunol.* 21(1): 21-41. 1931.—The paper begins with a review of recent literature on application of the principles of theoretical physics and physical chemistry to the behavior of proteins, particularly the relation of the phenomena involved to immune reactions. It is shown experimentally that diphtheria toxin-antitoxin flocculation (Ramon method) first takes place at the liquid-air surface, where surface energy is at a minimum. In experiments in which serum and toxin were mixed in uniform proportion, it could be demonstrated that flocculation-reaction time varies according to size of tubes used and volume of mixture. From these observations the author concludes that the specific attraction forces between toxin and antitoxin molecules cause flocculation, but that reaction time is determined by the free energy. The flocculation-reaction time, therefore, may be affected by the attraction and repulsion of the particles in the toxin-antitoxin system, which decrease the free surface energy to a minimum, with resulting flocculation. This time decrease in free energy is a function of both the hydrophilic and hydrophobic ions, depending on the thickness and density of their interfaces, and should be demonstrable by surface-tension measurements. Tests of toxin made during its production in infusion-free peptone medium and particularly after purification by ultrafiltration, and also results of tests made with an antitoxic serum in which the protein particles had been denatured by heat, showed that the shorter the flocculation-reaction time, the higher the surface tension, measured in dynes. The experiments indicate that changes in the colloidal state of the toxin-antitoxin interfaces probably result in changes in reaction time.—*K. C. Berthelsen.*

16474. BERTHELSEN, KNUD C. Studies of the flocculation-reaction time in the course of immunization and the quantitative and qualitative changes of the proteins. *Jour. Immunol.* 21(1): 43-67. 1931.—A study was undertaken of such physicochemical constants of blood serum as surface tension, viscosity, protein fractions, and the inorganic substances in relation to the flocculation-reaction time. It seemed probable that the interaction taking place during development of antibodies may occur between the globulin, and possibly also the lipoids, and the electrolytes, altering the dispersion degree of the globulins between the hydrophilic and the hydrophobic ions, and that this may be indicated by changes in surface activity during immunization and may also affect the flocculation-reaction time. The flocculation-reaction time of 23 horses showed in general a continuous increase during immunization. 12 of them were followed for alterations in protein fractions during immunization with different methods and toxins. Quantitative changes in protein fractions were without effect on flocculation-reaction time. The alterations may, therefore, be related to qualitative characteristics of the antibody-protein complex. However, no qualitative differentiation in the protein complexes could be demonstrated by surface-tension measurements. It is concluded that it would be desirable to investigate further the electrokinetic phenomenon to gain a better knowledge of the qualitative characteristics of the immune protein.—*K. C. Berthelsen.*

16475. BERTHELSEN, KNUD C., and PHILIP P. MURDICK. The distribution of electrolytes in serum during immunization. *Jour. Immunol.* 21(1): 69-84. 1931.—The biological significance of the common electrolytes is briefly discussed. It is suggested that exchange or variation in equilibrium of electrolytes, or associated phenomena, may furnish the chemical stimulus necessary for antibody formation. At progressive stages of immunization, before and after injection of diphtheria toxin, the diffusible Ca, non-diffusible Ca, and total base in the blood of a series of horses were determined. The diffusible and non-diffusible P was also estimated, at weekly intervals. Ultrafiltration technique was employed to separate diffusible from non-diffusible constituents. The diffusible Ca in the serum displayed a noticeable tendency to decrease in the 24-hr. period following injection of large amounts of toxin. A somewhat similar tendency was also noted for total Ca and total base. There was considerable fluctuation in amounts of total and diffusible P but with no apparent relationship to development of immunity, although these values tended to decrease as antitoxic potency increased. It is suggested that the drop in diffusible Ca, and possibly also in other electrolytes, is a chemical factor related to the immunological stimulation process.—*K. C. Berthelsen.*

16476. BRUYNOGHE, et ADANT. Influence de quelques halogènes sur les protides. *Bull. Acad. Roy. Méd. Belgique* 10(5): 298-316. 1930.—Experimental studies (not here reported in detail) on the nature of the specificity of antigens showed that iodine, in combination with sera, removes specificity and transforms them all into equivalents of each other, no matter what the species from which obtained. Such iodized antigen has no inhibitory action on production of precipitate in mixtures of the same serum unmodified, and its corresponding antiserum. Precipitation of iodized proteins takes place as if the insolubility in the serum were produced by a non-complex antigen. The fixation of iodine on non-antigenic proteins does not render them antigenic. Br produces changes in sera similar to those produced by iodine: loss of specificity and transformation into undifferentiated, identical antigens. Bromized proteins, however, may be differentiated from iodized proteins in precipitation reactions. Under the influence of Cl, serum loses its antigenic properties and is not affected either by precipitins of normal sera or by those of iodized or bromized sera.

16477. BUBLITSCHENKO, L. Die Immunität und die Antivirushautreaktion bei Schwangeren und Wöchnerinnen. *Monatsschr. Geburtsh. u. Gynäkol.* 83(3): 191-203. 1929.—Tests were made by intracutaneous injection of 0.2 cc. of Besredka's staphylococcus and streptococcus antivirus. The antivirus used consisted of filtrates both of cultures of streptococci and of staphylococci; the organisms were derived from cases of puerperal infection. Tests were made on women in various stages of puerperal infection and on those with various infections of the uterus and adnexa. On the basis of numerous clinical and experimental observations, the author concludes: The skin reaction following injection of antivirus is due to a specific substance in the filtrate. Staphylococcus antivirus gives more frequent and more strongly positive skin reactions than does streptococcus antivirus. Women who had previously suffered from infections with staphylococci and streptococci gave the strongest skin reactions to the respective antivirus. Failure of the reaction to occur in an infected patient is evidence of the presence of a severe and probably fatal infection. Strong reactions in septic diseases give a good prognosis. During the course of an infection, the skin reaction to antivirus may become weak and return to a strongly positive reaction after recovery. The skin reaction to antivirus is recommended as a simple test for following the severity of infection. Intracutaneous injections of antivirus serve as vaccinations, increasing the resistance.—*S. Bayne-Jones.*

16478. CARLETON, H. M. Studies on epithelial phagocytosis. I. *Proc. Roy. Soc.* [*London*] *B* **108(755):**

1-10. 2 pl. 1931.—In experiments on 40 rabbits, suspensions of Hydrokollag (a proprietary colloidal suspension of graphite), carmine, cocoa butter, and live and dead *Staphylococcus aureus* and tubercle bacilli, were aseptically introduced by injection either into the vagina or into the upper end of 1 uterine horn exposed by median laparotomy. Hydrokollag, carmine, and bacteria were phagocytosed by non-ciliated columnar cells of the vaginal epithelium; cocoa butter and olive oil were absorbed by, and appeared as fatty globules in, non-ciliated columnar cells of vagina and uterus, but this is regarded as absorption rather than phagocytosis. These columnar cells have, distally, blunt projections resembling pseudopodia; they possess a layer of mucin and are presumably sticky and able to hold foreign bodies. The need for stringent criteria in defining phagocytosis is stressed, and the criteria employed are described. They are: (i) ability to bring into the same focal plane some portion of the nucleus and the suspected ingested material; (ii) to identify the cell-membrane as being definitely outside the particles. The presence of cytoplasmic vacuoles around ingested particles such as carmine and staphylococci is additional evidence of phagocytosis.

16479. CONSOLI, NICOLA, e FRANCESCO PIVETTI. Sulla persistenza della reazione delle termoprecipitine negli organi pestosi umani conservati. [Persistence of thermoprecipitins in preserved human plague organs.] *Atti Accad. Gioenia Sci. Nat. Catania* 15(4): 1-7. 1927. —The thermoprecipitin test is obtained in human plague organs preserved in alcohol (even after 2-3 yrs.) or in formalin. Organs giving the most intense reactions are, first, the lungs, then the buboes, then the spleen, and, last, the liver and kidneys.—*E. Ponzi.*

16480. COTONI, L., et N. CHAMBRIN. Sur l'immunité passive obtenue à l'aide du pneumocoque III. *Ann. Inst. Pasteur [Paris]* 45(6): 706-726. 1930.—In attempts to immunize rabbits and horses with pneumococcus Type III, 3 antigen preparations were used: (a) clear centrifugate of macerated cells; (b) dried cells; and (c) alcohol-ether extract of cells. They were given intravenously, subcutaneously or intramuscularly; on the whole, the doses were well-tolerated. Some differences were noted in the tests on sera taken from rabbits and horses. The authors recommend small, repeated doses of dried cells for immunization.—*L. A. Barnes.*

16481. DERICK, CLIFFORD L., and MARSHALL N. FULTON. Skin reactions of patients and normal individuals to protein extracts of streptococci. *Jour. Clin. Investigation* 10(1): 121-138. 1931.—Intracutaneous tests with purified nucleoprotein fraction of a hemolytic and of a green streptococcus were studied in 670 individuals. The antigens used were purified till their N content was constant. A similar protein from baker's yeast was used as a control in part of the work. The hemolytic streptococcus nucleoprotein almost uniformly induced stronger reactions than did the green streptococcus antigen. In individuals over 15 yrs. old, age plays no part in determining the presence or absence of sensitiveness to these antigens. In children under 15 yrs. old there is with increase in age a gradually increasing proportion of positive over negative reactors. This proportion is influenced markedly by the presence or absence in children of rheumatic infection, the % of positive reactors among the rheumatic group outnumbering that in the non-rheumatic group by a wide margin. Since positive reactions may be obtained in a great variety of diseases, the test has no specific diagnostic value. The disease which one has at the time of testing appears to bear some relationship to the state of sensitiveness. Whether this is cause and effect or merely an association more apparent than real, the present work does not reveal.—*Author's summary.*

16482. DIENES, L., and E. W. SCHOENHEIT. The antigenic substances of the tubercle bacillus. V. The antigenic substances of the synthetic culture medium. *Jour. Immunol.* 18(4): 285-314. 1930.—In addition to the carbohydrate-precipitable substance, 2 antigenic materials can be separated by acid precipitation from filtrates of tubercle bacillus cultures in Long's synthetic medium. These 2 fractions differ in serological reactions, antibody production, and in connection with the tuberculin reaction in guinea pigs. The acid-precipitable antigen stimulates production of specific antibodies in tuberculous animals. Antibodies formed by the acid non-precipitable fraction failed to react with homologous antigen, acid precipitate, or with concentrated culture medium; but strong reactions were obtained with bacillary emulsion. It is concluded that in the culture medium these 2 fractions are united in a higher complex which has a specificity markedly different from that of the isolated antigens, and in the reactions of which the effect of the isolated antigens does not appear. This complex antigen may be responsible for production of antibodies by concentrated culture medium and acid filtrate, although it often gives little or no reaction with these sera.—*L. A. Barnes.*

16483. DONAGHY, FRED, and ROSCOE R. HYDE. Immunity to Walker's rat sarcoma no. 1. *Amer. Jour. Hyg.* 14(2): 495-501. 1931.—Resistance to a certain transplantable spindle-cell sarcoma differed greatly in 3 strains of rats observed: (1) in the "Philadelphia" strain, tumor growth was rapid; (2) the "Hygiene" strain was 90% resistant to implants; (3) in the "Littlestown" strain about 20% of the animals supported tumor growth to thumb size, when generally it receded. Experiments involving several hundred rats were made to develop immunity in the susceptible "Philadelphia" strain by various methods, including removal of the implant after growth in the host, feeding tumor tissue, feeding tissue from resistant rats, injection of immune sera from rabbits and guinea pigs, injection of sera and whole blood from chickens treated with sarcoma no. 1, and allowing the young of susceptible "Philadelphia" stock to suckle tumor-bearing mothers. None of these methods produced immunity. Embryo skin from embryos of the resistant "Hygiene" stock was implanted in 20 "Philadelphias," giving complete immunity after absorption of the embryo skin. Implantation of embryo skin from the susceptible stock produced immunity in 17 of 20 "Philadelphias." The invariable observation of splenic hypertrophy in tumor-bearing "Philadelphias" led to injection of 10 susceptible rats with emulsion of spleen from 2 tumor-bearing rats; no tumors developed, but the treated rats proved resistant to subsequent tumor implants. The immunity in this case is not to be ascribed to the fact that the spleens were from tumor-bearing animals, as it is known that homologous normal spleen is an effective immunizing agent.

16484. DUDGEON, LEONARD S., and H. K. GOADBY. The examination of the tissues and some observations on the blood platelets of rabbits at intervals of five minutes, and later, after intravenous inoculations of Staphylococcus aureus and Indian ink. *Jour. Hyg.* 31 (2): 247-256. 3 pl. (1 col.). 1931.—Live and dead *Staph. aureus* and massive doses of India ink and colloidal Ag were intravenously injected into rabbits. Any particles injected into the circulation cause accumulation of polymorphs in the lung capillaries. Inert colloidal particles such as India ink are clumped in the capillaries of the lungs, liver, spleen and kidneys, and are phagocytozed by endothelial cells. The staphylococci, live or dead, are nearly all held up in the lungs, where they are actively phagocytozed by the polymorphs within 5 min. of an intravenous injection. Subsequently the cocci are distributed to other organs, where phagocytosis continues mainly by polymorphs, but in the liver also by Kupffer's cells. Special attention is drawn to the localization of the cocci in certain areas in the kidneys. Platelet counting on animals injected with various substances showed that there is an agglomeration of the particles with the platelets, which are consequently removed from the circulation. In the case of the inert particles, the platelets are then restored to the circulation. With organisms (*Staph. aureus*), some

of the platelets appear to be completely removed from the blood together with the bacteria.—*Authors' summary.*

16485. [ĖL'BERT, B. ĭA.] ЭЛЬБЕРТ, Б. Я. К механизму инфекции и иммунитета у белых мышей, инфицированных палочкой паратифа B-Schottmülleri. 1-е сообщение. [Infection and immunity mechanism in white mice infected with paratyphoid B-Schottmüller. I.] Журнал Микробиологии и Иммунобиологии (*Jour. Microbiol. et Immunobiol.*) 7(2): 197-220; French summary, 237-238. 1930.—Experiments were conducted on 399 white mice. After peroral ingestion, bacteria were found in mesenteric and cervical ganglia. However, in some cases they broke through this barrier and were found in subaxillary and inguinal ganglia. Only in exceptional cases were they found in blood, liver or spleen. The mechanism of subcutaneous infection was based on maximal filtration by subaxillary and inguinal ganglia. Where these 2 filters fail, dissemination in the organism occurred. Subcutaneous vaccination with dead bacilli did not prevent bacterial activity in the mesenteric ganglia. Thrice repeated subcutaneous vaccination with live bacilli 3 wk. prior to infection did not cause more rapid destruction of bacteria in the mesenteric ganglion. Blockade of the reticulo-endothelial system resulted in generalized infection, however, not always resulting in death, but in some cases becoming chronic.

16486. **FAMULENER, L. W. A method for the standardization of autogenous vaccines (bacterins).** *Acta Path. et Microbiol. Scandinavica Suppl.* 3: 119-122. 1930.—The method employed consists of centrifuging a rich broth culture, or a physiological saline suspension of bacterial growth from a solid medium, in the regulation Hopkins vaccine tube, for ½ hr. at approximately 2800-3000 revolutions per min. in a machine carrying a 30 cm. head. The bacterial material is deposited in the collecting portion of the tube at practically maximum concentration. The supernatant is removed; then sufficient sterile physiological saline is added to give a 1% suspension of organisms. This is placed in a sterile test tube, and heated in a water bath at the minimum temp. to kill the organism after 1 hr. Controls are made by inoculating a few drops of the heated suspension in suitable medium, then sufficient tricresol (10% emulsion in distilled water) is added to give a 0.25% concentration. This constitutes the "stock" suspension, from which the "testing" and "therapeutic" vaccines are prepared. An arbitrary unit was adopted, based on results of numerous tests on normal and hypersensitive individuals. The unit may be defined as that volume of bacterial substance (killed) represented by 0.01 cc. of a 1% suspension in physiological saline containing 0.25% tricresol.—*L. W. Famulener.*

16487. **FELIX, A., and M. RHODES. Serological varieties of typhus fever.** *Jour. Hyg.* 31(2): 225-246. 1931.—Fletcher and Lesslar's observations on 2 serological types of tropical typhus have been fully confirmed. The antigenic relationship between the indologenic *B. proteus X 19* and the non-indologenic Kingsbury strain is of the same order as that obtaining between *X 19* and *X 2* types of *B. proteus X*. The Kingsbury strain is an antigenic variant derived from the original *X 19* culture and represents another serological type of *B. proteus X*. The symbol "XK" is suggested for this type. Sera from cases of classical European typhus and of endemic typhus of the U. S. A. and of Australia have been tested for occurrence of main and group O agglutinins for the known types of *B. proteus X*. H agglutination as source of error in the diagnosis of typhus cases is illustrated by examples. Sera from cases of tsutsugamushi from Sumatra and Japan react with type XK like the Malayan cases of this disease described by Fletcher and co-workers. This latter reaction is of the order of group-O agglutination. Antigenically, the virus of tsutsugamushi may correspond to another serological type of *B. proteus X* as yet unknown. The data published on the serum reactions in Rocky Mountain spotted fever and in "fièvre exanthématique" of Marseilles are analyzed. These 2 diseases may represent further serological varieties of typhus. The significance hitherto attached to negative agglutination tests with *B. proteus X* and to negative cross-immunity tests with some typhus-like diseases, requires revision in the light of recent observations.—*Author's summary.*

16488. **FELIX, A. Specific and non-specific serum reactions in typhus fever.** *Jour. Hyg.* 31(3): 382-402. 1931.—In all species tested—rabbit, guinea pig, chicken and horse—normal agglutinins for *B. agglutinabilis* U_2 were far more abundant than those for *B. proteus X 19*. Human serum reacts in the same manner. Wassermann-negative sera were employed as normal sera. Their reaction in Weltmann's globulin test was also negative. Wassermann-positive sera from cases of syphilis and sera from lepers gave distinctly higher agglutination reactions with U_2 than normal human sera. On X 19, however, those sera do not exercise any increased agglutinating action. Similar, though somewhat stronger, reactions with U_2 are obtained with typhus sera. However, this reaction is far from being uniformly positive in typhus, while this is the case with the X 19 reaction. The discordance between these results and those of Wilson and of Fletcher, Lesslar and Lewthwaite is due to the failure by these workers to employ suitable controls. In syphilis and leprous sera, high titers of agglutination with U_2 coincide with globulin-increase as indicated by the Weltmann reaction. The summation effect of the non-specific agglutination by gelatin and the action of specific immune agglutinins described by Weil, are again demonstrated. The combined action of an abundance of preformed normal agglutinins and of augmented serum colloids is suggested as one of the factors involved in increased heterologous agglutination (poly-agglutination). *B. agglutinabilis* U_2 is a typical representative of "poly-agglutinable" organisms; *B. proteus X 19*, however, is not liable to the action of "poly-agglutinating" sera.—*Author's summary.*

16489. **FELTON, LLOYD D. The variables in the mouse. Protection test of antipneumococcus serum.** *Jour. Immunol.* 19(6): 485-509. 1930.—The 2 variables are: the experimental animal; the test culture. The 1st can be compensated for by using 10 mice for each dilution of serum and regarding 6 of 10 as the end-point. With regard to the 2nd variable, the author concludes that: Consistent results over a period of time may be obtained with 1 strain of organism if maximum virulence is maintained. With lethal doses of 250,000-5,000,000, the relationship of varying doses of culture to varying dilutions of serum follows the law of multiple proportions. It is the changing ratio between virulence and power to neutralize antibacterial immune-substance that is responsible for the widely divergent results with various strains of pneumococci. Both virulence and neutralizing power of pneumococci may be increased by mouse passage. Reproducible results may be obtained only when the virulence and neutralizing power of the test culture are known, and then only when estimation is made by comparison with a standard serum.—*R. W. Jung.*

16490. **FRIEDENREICH, V., et G. WAALER. Sur les sous-groupes du groupe sérologique A. Y a-t-il une relation entre la sensibilité du récepteur de globules et de l'apparition de l'agglutinine α_1 "irrégulière"?** *Compt. Rend. Soc. Biol.* 106(9): 773-776. 1931.—In researches on the process of immunization, the apparent co-existence of antigen and corresponding antibody free in the blood of immunized animals has been repeatedly noted. This paradoxical finding is, however, an illusion, for with a sufficiently delicate technique it can be shown that antigen and antibody are not strictly homologous. Analogous observations have been made on isoagglutination, and some authors consider that individuals exist with the blood-formula $A\beta\alpha$, i.e., with receptor A and agglutinin α in the blood at the same time. In such cases, it may be accepted that the corpuscles were of type A_2 and the agglutinin was α_1

(not α); i.e., antigen and antibody were not strictly homologous. Agglutinin α seems to occur only in individuals with receptors weaker than the average. Bernstein supposes that all individuals form α as well as β, though β alone appears normally in A individuals, because α is absorbed by the A receptors proper to the organism, suggesting that when the receptors happen to be feebly developed they may not succeed in completely eliminating α. This explanation does not hold good when the receptors are not abnormally feeble A-receptors, but happen to be another kind of A-receptor (A_2) which occurs in 1 out of 5 individuals. Nevertheless, certain facts indicate that a relation does exist between avidity of receptors and appearance of an "irregular" agglutinin α_1. The authors examined numerous sera for presence of α_1 agglutinin and for avidity of A_2 receptor in A_2 individuals whose serum contained the "irregular" agglutinin α_1, and found that A_2 receptor was feeble and that in A_2 individuals who had most α_1, A_2 receptor was much weaker than the average. On this and other grounds, the authors support Bernstein's hypothesis.—*R. T. Hewlett.*

16491. **FUJI, Y. Über Resorption von körperfremden Proteinen von der Haut. Gleichzeitig eine Methode für die Herstellung hochwertiger präzipitierender Antisera.** *Japanese Jour. Med. Sci. VII. Social Med. & Hyg. Trans. & Abstracts.* 1(1): 45-59. 1930.—Rabbits treated with salve made of horse serum in lanolin showed the presence of horse serum in their serum when tested with an anti-horse precipitin serum, thus showing definite absorption of horse serum. After a latent period, precipitating antibodies appeared in the serum. The titer, which reached its height in a few days, was frequently higher than that attained by the usual intravenous methods of immunization. If such animals received a 2nd application of salve, after the original antibodies had disappeared the precipitin titer rose again and was, as a rule, higher than before. The latent period also was shorter. When these animals immunized by percutaneous methods were given a single intracutaneous dose of horse serum there was a rapid drop of precipitins, followed by a rise to extremely high titer. These antibodies persisted for a surprisingly long time at a high level, in some cases over 1 yr.—*C. M. Downs.*

16492. **GINS, H. A. Experimentelle Vaccineinfektion als Hilfsmittel zur Erforschung von allgemeiner Infektion und Immunität.** *Zeitschr. Hyg. u. Infektionskr.* 110(1): 133-143. 1 fig. 1929.—The author discusses differences in results of vaccination during the last 15 yrs. The more virulent vaccines of to-day are due to increase in amount of virus. The success obtained in vaccine infection and immunity in recent yrs. is due to intensification of vaccines by passing from human to animal vaccines, and to continuous improvements in preservation methods. Vaccination causes not only typical infections but also intensive immunization, as is evidenced by nationwide vaccinations which the author considers to be the best proof for a formation of general infections after cutaneous insertion of virus. Such inserted infections lead to general immunity. The author's theoretical discussion of the relationship of vaccination to mucous membranes shows that vaccine immunization is not caused by injuries to either skin or mucosa, but by 2 other possible ways: (1) absorption through bronchioles and alveoli, or (2) through mucous membranes of nose and throat. The importance of tonsils during vaccine and other infections is also pointed out, and it is the author's view that organs whose physiological function is the maintenance of a continuous flow of leucocytes towards the cavities of the mouth and throat also play an important rôle in the increase of vaccine virus.—*O. A. Tischer.*

16493. **HACH, IW., M. BORODAJ, und V. MELNYK. Studien über Gewebeinfektion und Gewebeimmunität.** *Zeitschr. Immunitätsforsch. u. Exp. Therapeut.* 54(3/4): 251-268. 3 fig. 1928.—Cultures of *Staphylococcus aureus* were injected intravenously into rabbits, which were examined at intervals during the rapidly fatal septicemia ensuing, to determine the number of bacteria in various organs. Plate cultures were made from the circulating blood obtained by heart puncture and, after killing the animal, from the spleen and skin, using weighed and measured amounts of organs. In the first few hrs. after injection the greatest number of bacteria per unit wt. of organ were found in the spleen. This the authors attribute to active phagocytosis of the bacteria from the blood of the reticulo-endothelial cells of that organ. As the infection progressed there was a marked gradual diminution of bacteria in the spleen and a corresponding increase of those in the skin, which reached its maximum in animals examined in extremis or after death from infection. These observations lead the authors to believe that the skin plays some special rôle in acute fatal staphylococcus infections.—*A. Zeissig.*

16494. **HAMEDY, A. Le phénomène d'iso-agglutination chez les chevaux producteurs de sérum antitoxique.** *Compt. Rend. Soc. Biol.* 106(12): 1097-1099. 1931.—The blood of 11 horses producing antidiphtheric serum, was examined at the beginning and end of a 2-mo. period during which the animals continued to receive injections of antigen and were bled repeatedly. 8 of the 11 changed blood groups during this period. Group O showed the least tendency to change, AB was a little less stable, and A and B were least stable. Sera of 2 horses in group AB agglutinated all but 3 sera of 115 from normal and hyperimmunized horses. There is no evident relation between antitoxic power of sera of hyperimmunized horses and their iso-agglutination reaction.—*E. Weiner.*

16495. **HAXTHAUSEN, H., und AXEL THOMSON. Brucella-Ausschlag bei Tierärzten. (Eine eigentümliche, professionelle Hautaffektion, wahrscheinlich allergischer Natur, hervorgerufen von Bac. abortus Bang.)** *Arch. Dermatol. u. Syph.* 163(3): 477-491. 4 fig. 1931.—About 1 of each 3 veterinarians graduated in Denmark since 1915 has shown a skin disease [5 cases described] characterized by follicular papules on the arms, accompanied by pustules and necrosis. It appears directly after delivery of the placenta in cows with infectious discharge and has a tendency to reappear after each delivery. The eruption is probably caused, not by actual skin infection with *Bacillus abortus* Bang, but by an allergic reaction from "toxins" of the bacillus; it could be reproduced by "abortin" produced similarly to tuberculin (all but 1 control was negative). The allergic condition itself was probably due to a preceding infection. The skin affection was not accompanied by fever or other general symptoms and showed no similarity to undulant fever.—*From author's summary (transl.).*

16496. **HECHT, ADOLF F. Zur Immunobiologie fieberhafter Erkrankungen.** *Wien. Klin. Wochenschr.* 40(35): 1097-1101. 7 fig. 1927.—A study of serum sickness shows that when a fever-producing agent does not multiply in the body, the curve is discontinuous, the intervals being 4-6 days; the other manifestations, as urticaria, are also discontinuous. On long duration, the type of fever differs, becoming continuous, intermittent or remittent. A change in type does not necessarily mean a change in an infection; it may be only a late body reaction. There is no direct relation between fever course and local manifestations. Manifestations of serum sickness form a part of the syndrome of many infections.—*J. T. Myers.*

16497. **HEIDELBERGER, MICHAEL, and FOREST E. KENDALL. The amount of circulating precipitin following the injection of a soluble antigen.** *Science* 72 (1862): 253. 1930.—Using R-salt-azo-benzidine-azo-egg albumin as antigen, each of 2 rabbits was injected with a total of 21.6 mgm. of this purplish-red diazo protein dye. 10 days after the last injection the animals were bled, and the wt. of circulating precipitin was calculated for each. One contained 168 mgm. of such precipitin or 7.8 mgm. per mgm. of antigen injected; the other contained 138 mgm. or 6.4 mgm. of circulating precipitin per mgm. of antigen injected. The figures tend to indicate that antigen does not participate in building up the specific antibody complex.—*A. Boyden.*

16498. HULSHOFF POL, J. P. G. Über die Beziehung der Präzipitine zu den Agglutininen. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 61(1/2): 99-114. 1929.—The problem was to try to give to precipitating antisera the properties of agglutinating antisera by changing antigen from a colloidal solution to a suspension. Precipitating antisera were produced in rabbits by injection of casein and horse serum. The flocculation reaction was used, with dilution of antiserum or antigen, or both. The most satisfactory adsorbents were kaolin, MgO, rosin, and zinc stearate. Results showed that precipitating antisera do acquire the characteristics of agglutinating antisera when tested against suspended antigens. The antisera gave higher titers with suspended antigen than with colloidal antigen solutions, and could therefore be diluted much more than in the usual case of precipitins. The adsorbed suspended antigens could not be diluted very much without obtaining negative reactions. These results together with the discovery that the first antibodies against casein and horse serum to appear during injection reacted with the suspended antigen and not with the dissolved antigen, make it probable that precipitins and agglutinins are identical antibodies whose apparent differences are due to the physical state of the antigen. On the other hand, heat seemed to affect the antibodies reacting against dissolved antigen more than those reacting against suspended antigen, but this result is uncertain.—*A. Boyden.*

16499. HUNTEMÜLLER, O. Die Wirkung der Lichtstrahlen auf die natürlichen Abwehrkräfte (Alexine) im Blutserum. II. Ultrarote und Helligkeitsstrahlen. *Strahlentherapie* 40(4): 743-749. 1931.—The author studied the effect of light on the natural defense mechanism of the body, the "alexins" of Buchner. If normal or low, the alexin content of the blood serum increases first after irradiation; later it decreases slowly. If the original level in the blood is high it decreases first and then increases slowly to the original level. The 1st reaction is said to be due to a direct effect on the cells, the 2nd appears with the development of erythema and is presumably due to the effect of decomposition products of the cells on the site of formation of the alexins. These changes occur wavelike for some time after irradiation with ultraviolet. Sunlight and Sollux light, the latter having no ultraviolet, act in the same way; infra-red, however, acts more slowly but it is nevertheless very effective as to changes in alexins.—*W. F. von Oettingen.*

16500. [IMSHENETSKIĬ, A. A.] ИМШЕНЕЦКИЙ, А. А. О проходимости кожи для раствора трипановой сини в связи с учением о кожном иммунитете Безредка. [Skin permeability for trypan blue solution and Bezredka's theory on skin immunity.] Журнал Микробиологии и Иммунобиологии (*Jour. Microbiol. et Immunobiol.*) 7(2): 159-168; German summary, 234. 1930.—Experiments were made on 23 rabbits: in 14, with trypan blue compresses applied to the skin; in 4, trypan blue applied directly; in 3, antivirus compresses; and in 2, physiological saline compresses. It was found that in 48 hrs., compresses of 1% solution of trypan blue caused in the skin distinct exudative infiltrative inflammation, accompanied by necrobiotic alterations of epithelium and of hair follicles. These regions of the skin with injured epidermis, and the hair follicle walls, served as entrance for the dye penetrating into the tissue lymph of the skin proper. The dye, then, was adsorbed by histiocytes, which accumulated it in their protoplasm in granular form; grains of dye were found in special polymorphonuclear leucocytes, situated mainly under the epithelium. Tissue lymph transmitted the dye into the regional lymphatic ganglia, where it was deposited in some reticular cells of stroma and in histiocytes of the capsule. External application of the dye without compress was accompanied by its accumulation in the corneum, mostly in its surface layers; in the skin proper it was absent.

16501. JAKHNIS, B., und S. CHAGALOWA. Neue Ergebnisse der Ukrainischen Kommission zum Studium der Säuglingsimpfung mit BCG. Impfung von je einem der beiden Zwillinge. *Zeitschr. Tuberk.* 61(3/4): 191-193. 1931.—After inoculating the weaker partner in 16 pairs of twins, with BCG (20 uninoculated pairs as controls), no injurious effect was observed; the inoculated twins had a lower mortality and usually developed better than the uninoculated partners.

16502. JUNDELL, I., och H. MAGNUSSON. BCG-försök å svin. (BCG tests on pigs.) [With English summary.] *Skandinavisk Vet.-Tidskr.* 21(9): 271-288. 1 fig. 1931.—Of 24 suckling pigs free from tuberculous infection, 8 were vaccinated per os with 2 mgm. of BCG vaccine on 3 successive days, 8 were vaccinated subcutaneously with 10 mgm., and 8 were kept as controls; of the last, 6 were infected at the same time as the vaccinated animals, the other 2 being kept as healthy controls. The animals were infected 7-8 wks. after vaccination per os with a single dose estimated to contain 2,000 million tubercle bacilli and consisting of an emulsion of a tuberculous cow-udder. All the vaccinated animals developed tuberculosis within 19-21 wks. after being infected, changes being almost as progressive as in the controls. The most that can be said is that vaccination delayed the infection slightly. The average wt. of the healthy controls was 82.5 kgm. at an average age of 174 days; that of the infected controls was 60 kgm. at an average age of 210 days. The pigs vaccinated per os showed an average wt. of 75 kgm. in 213 days; those vaccinated subcutaneously, 73 kgm. in 211 days.—*From authors' summary.*

16503. KATO, N. Beiträge zur Kenntnis der Reinokulation bei experimentellem Rückfallfieber. [In Japanese, with German summary.] *Acta Dermatol.* 17(3): 189-217. 1931.—From experiments in inoculating mice with relapsing fever spirochaetes, treating them at various intervals with salvarsan, and reinoculating them, the author concludes that degree of immunity is in general independent of duration of latent stage. However, when treatments were begun the same number of days after the 1st inoculation, the degree of immunity was higher in mice in which the latency period was short and the sickness period long, than in those in which the relation was reversed. Yet when both latency and sickness were long, the degree of immunity might be lower and with lighter symptoms than in the opposite case. If the treatment were begun on appearance of the spirochaetes in the blood and reinoculation made 10 days after the last salvarsan injection, reinoculation was repeatedly positive and finally there was a negative immunity through accumulation. Thereby the height of the accumulated immunity decreased at every inoculation.—*From author's summary.*

16504. KAWAMURA, HIDEKU. A contribution to the knowledge on the toxin of the Shiga bacillus. *Kitasato Arch. Exp. Med.* 8(1): 1-23. 1931.—The specific toxin of dysentery bacilli is produced within the bacillary bodies and passed into the medium after they are dead. It is not a secreted toxin, and is quite different from Pfeiffer's so called endotoxin. Dysentery toxin becomes stronger after death of the bacilli but weakened with time. The combining power of the toxin with antitoxin increases in accordance with increase of toxicity after death of the bacilli and weakens with decrease of toxicity after a much longer time. In the dysentery bacilli a certain substance which changes into specific toxin may be found; this may be christened "toxinogen." It has neither toxic nor combining powers, but under certain changes it may be converted into another inert substance, "pretoxin," which has the power to combine with antitoxin. Further, it is converted into a toxic substance, which is the specific toxin. The changes may proceed still further and form a substance having neither toxic nor combining power, but not the substance known as "toxoid" as is the case with other sorts of specific toxins. The antitoxinogen of Shiga bacilli is found mostly in the bacillary bodies; therefore, fresh bacillary bodies are best fitted for immunization. A strong toxin can be obtained by cultivating the bacilli in a medium composed of very simple materials free of peptone, but the

toxin here obtained weakens very rapidly.—*H. Kawamura.*

16505. **KENNEDY, JAMES A. Isohemagglutination: the work of Jan Janský with a critical analysis.** *Jour. Immunol.* 20(2): 117-141. 1931.—Janský's classification is based on 3160 "cross-agglutinations" in which he utilized sera from 30 (32) individuals and corpuscles from 99. These "cross-agglutinations" are here reproduced from his work, and an orderly arrangement is made. His classification is based on 30 (32) individuals whose sera he used in the "cross-agglutinations"; it shows: Group I, 12 individuals; Group II, 10; Group III, 6; and Group IV, 2. Results of analysis of his series of "cross agglutinations" are given, and it is evident that Janský failed to realize that, in addition to grouping the sera used, he was also grouping the other individuals whose corpuscles only were employed. Consequently, his results should have been Group I, 40 individuals; Group II, 38; Group III, 20; and Group IV, 2; with a racial index of 1.8. 2 individuals (7524 F. B. and 7627 Š. J.) appear in his series, whose bloods do not fit exactly into the classification. It seems more logical to assume that the irregularity shown by the blood of 7524 F. B. was due to a low isoagglutinin "b" titer which was made ineffective by dilution, very short incubation period and possibly by temp. of incubation. The blood of 7627 Š. J. was exceptional. However, due to the fact that Janský did not include the serum of this individual's blood in his series, one is hardly justified in drawing definite conclusions regarding it. The French résumé given by Janský is here reproduced.—*J. A. Kennedy.*

16506. **KIGASAWA, T. Antigene Eigenschaften der Lysozyme.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 57(1/2): 146-152. 1928.—Contrary to Fleming's results, lysozymes were not found in the expressed juice of green leaves (*Robinia, Sambucus,* rutabaga) or of ripe fruits (plums, apricots, apples), or the juices of potatoes, beets, turnips, rutabagas or onions in any demonstrable quantity; the common radish, however, showed a positive lysozyme content. Lysozymes were found with much greater regularity in normal animal bodies, though the concentration was low except in certain substances (e.g., human tears, egg-white). In the guinea-pig organism the most productive source appeared to be the polynuclear leucocytes. The reason for this irregularity was not apparent. Experiments showed that the lysozyme of egg-white produced no antilysozyme in rabbits. Since Wolff was unable to produce anaphylaxis with the purified preparation, it seems improbable that lysozymes are of antigenic character.—*A. Bodansky.*

16507. **KIRKBRIDE, MARY B., KNUD C. BERTHELSEN, and ROSE F. CLARK. Comparative studies of infusion and infusion-free diphtheria toxin in antitoxin production and in standardization by the flocculation, subcutaneous, and intracutaneous tests.** *Jour. Immunol.* 21(1): 1-20. 1931.—Successful application to routine and experimental purposes, of diphtheria toxin produced with an infusion-free peptone medium is reported. In addition to the advantages of substituting known for unknown factors, the marked reduction in cost of infusion-free, as compared with meat-infusion, toxin, and the greater uniformity in potency, are pointed out. In comparative flocculation-reaction tests, infusion-free toxin compared favorably with meat-infusion toxin. The micrometer-syringe method was found less accurate than the "pipette method" in which larger volumes of toxin are used. A comparison of the flocculation-reaction test with the subcutaneous and intracutaneous animal method for determining diphtheria antitoxic values showed closer agreement with the subcutaneous tests. In titrations of sera from certain horses, wide variations were noted between results of flocculation and subcutaneous tests on the one hand, and those of the intracutaneous test on the other. The flocculation-reaction test was found satisfactory for preliminary estimations of antitoxic content of concentrated, as well as of untreated, serum. As antigen, infusion-free toxin compared very favorably with routine infusion toxin for immunization of horses in production of diphtheria antitoxin. Injections of purified (ultrafiltered), infusion-free toxin also appeared to produce an equal response in a small series of horses.—*K. C. Berthelsen.*

16508. **KLOPSTOCK, A., und G. E. SELTER. Über chemospezifische Antigene. IV. Anaphylaxiereaktionen mit chemospezifischen Antigenen.** *Zeitschr. Immunitätsforsch.* 63(5/6): 463-483. 2 fig. 1929.—Confirming Landsteiner's earlier results, the authors find that guinea pigs sensitized by subcutaneous injection with an atoxyl-protein compound are thrown into lethal anaphylaxis by intravenous injection with any atoxyl-protein-complex, irrespective of origin or nature of protein "carrier" of the atoxyl. Even guinea-pig proteins are functioning "carriers" of this chemical antigen. Lethal anaphylaxis, however, is produced only by an optimum dose of such atoxyl-protein-complexes, excessive doses acting as inhibiting agents. Isolated or uncombined atoxyl produces no demonstrable shock in hypersensitive guinea pigs, but acts as a desensitizing agent. Isolated atoxyl injected subcutaneously leads to no demonstrable intravenous sensitivity, but gives, however, a demonstrable cutaneous sensitivity both to uncombined atoxyl and to atoxyl-protein-compounds. Similar results were obtained by a parallel anaphylactic study with sodium metanilate, and metanilate-protein-compounds.—*W. H. Manwaring.*

16509. **KOYASU, Y. Über die Immunitätsforschung des experimentellen Rückfallfiebers. IV. Prävent- und Heilversuch mit dem Antispirochaetenserum. V. Über das Immunitätsphänomen in vivo.** [In Japanese, with German summary.] *Acta Dermatol.* 17(1): 1-30; (2) 79-117. 1931.—IV. Antispirochaete serum from a rat recovered from relapsing fever showed some prophylactic properties. Neither that nor sera from actively immunized or healthy rats or guinea pigs showed therapeutic action. V. Living spirochaetes were introduced directly into the blood stream (1) in mice recovered from relapsing fever and actively immunized, and (2) in healthy mice which had shown positive agglomeration and Rieckenberg reaction before injection. None showed spirochaetolysis, but in the previously infected mice the spirochaetes vanished suddenly from the circulating blood; in the others there was a slight decrease followed by 2-3 days' increase. When living spirochaetes were intraperitoneally injected into previously infected mice, they never appeared in the circulating blood; immobile, half-destroyed or agglomerated spirochaetes were found here, but within a few hrs. they disappeared from the peritoneal cavity. The data indicate a true immunity following recovery from relapsing fever; it is uncertain which cells or portions of the organism are chiefly concerned, but the author inclines to suspect participation of the capillary endothelial cells.—*From author's summary.*

16510. **KRAUS, R. Über aktive Schutzimpfung gegen Diphtherie und ihre experimentellen Grundlagen.** [Active immunization against diphtheria and its experimental basis.] *Jahreskurse Ärztl. Fortbildung* 19(10): 13-28. 1 fig. 1928.

Влияние ретикулоэндотелиального аппарата на течение возвратного тифа. [Immunity in recurrent fever. 1. Influence of the reticulo-endothelial system on the course of recurrent fever.] [With French summary.] Журнал Микробиологии Патологии и Инфекционных Болэзней (*Jour. Microbiol., Path. Gén. et Mal. Infect.*) 4(1): 69-91. 1927.

16512. **LANDSTEINER, KARL. Individual differences in human blood.** *Science* 73(1894): 403-409. 1931.—This Nobel Prize Lecture by Landsteiner, given at Stockholm, deals not only with the 4 blood groups for the discovery of which the prize was recently awarded, but also with individual differences of human blood in general. The 4 human blood groups are described and also the new factors, M and N, and the heredity and forensic appli-

cation of both sorts of properties are discussed. These new factors, and also the sub-groups, increase considerably the variety of human blood and support the view that practically every human blood may be different from every other—a result previously established for some animal spp. Thus, a connection is established with the remarkable individual specificity of the transplantation of tissues. The substances underlying these individuality reactions are, in all likelihood, not proteins. The latter part reviews the subject of the use of blood groups for blood transfusion.—*P. Levine.*

16513. **LANDSTEINER, K., and PHILIP LEVINE. The differentiation of a type of human blood by means of normal animal serum.** *Jour. Immunol.* 20(2): 179-185. 1931.—The factor described as "P" and demonstrated by means of immune agglutinins for human blood can be recognized also with the aid of several other reagents, viz., atypical agglutinins present in some human sera and also normal animal sera (beef, horse, pig, rabbit). The 3 sorts of antibodies give parallel reactions, but while 2 of the reagents are difficult to procure, normal animal sera furnish a readily available material. The property P was studied in 71 families and in 4 families with both parents giving negative reactions. for P; all of the 18 children reacted negatively. These results confirm those previously obtained by the authors in tests with atypical human agglutinins.—*P. Levine.*

16514. **LAWSON, GEORGE B. Isohemagglutinins in the lower animals.** *Jour. Lab. and Clin. Med.* 15(7): 629-632. 1930.—Experiments failed to demonstrate either auto- or isohemagglutinins or auto- or isohemolysins in the blood of guinea pigs and rabbits; nor were heterologous agglutinins or heterologous hemolysins uniformly present in the serum of either of these animals when tested against the erythrocytes of the other. On the other hand, when human blood was used with that of guinea pigs, there was constant agglutination. Results of the work on monkeys indicate that possibly the blood of these animals can be grouped in a manner similar to human blood.—*F. W. Hachtel.*

16515. **LEVISON, WILHELM. Komplementbestimmungen bei Herz- und Kreislaufkranken.** *Zeitschr. Ges. Exp. Med.* 78(5/6): 728-732. 2 fig. 1931.—Complement was determined in 60 sera, of which 50 were from cardiac cases (12 compensated, 38 decompensated). In the decompensated cases, complement values were irregularly increased, normal, and decreased. Of the compensated cases, 12 showed increased and 4 normal, complement content. Increased complement was found mainly in valvular defect. Hepatic stasis was generally accompanied by increase in complement. In diluted serum through which CO_2 has been conducted in vitro, complement may disappear; in undiluted serum so treated, complement may increase.

16516. **LINZENMEIER, und JERNAKOFF. Blutsenkungsgeschwindigkeit und reticuloendotheliales System.** *Zeitschr. Ges. Exp. Med.* 78(3/4): 438-450. 1931.—The reticulo-endothelial system (R.-E.) was blocked with collargol in 20 rabbits. After medium and extreme blockade, sedimentation was somewhat, but not greatly, accelerated, possibly because of the anemia or emaciation produced. In rabbits previously infected intra-abdominally with *B. coli*, a decided acceleration of the sedimentation appeared 2-3 days later. After a 3-day moderate blockade of the R.-E., the sedimentation rate was slightly accelerated. The animal in which there was first a moderate blockade of the R.-E. with collargol and later on, intra-abdominal infection with coli, showed the same acceleration of sedimentation rate as the non-blockaded controls. Hence, it appears that either the sedimentation rate is not affected by the state of the R.-E. or colloid injection does not inhibit the functioning of that system.—*From author's summary (transl.).*

16517. **LUMSDEN, THOMAS. Tumour immunity.** *Amer. Jour. Cancer* 15(2): 563-640. 1 pl., 56 fig. 1931.—The author gives a simple technique for growing cancer cells and normal tissue cells in vitro, using pure serum rather than plasma or embryo extract. By treating such cultures with immune serum prepared by injecting animals (sheep) with the minced pulp of sterile cancer tissue, anti-malignant-cell bodies lethal to cancer cells but harmless to normal tissue cells can be produced. An active immunity against cancer may be induced by gradually destroying an actively growing tumor in rats by injection of antiserum or formalin into it—so called "autovaccination"; the animal is immune to subsequent tumor transplants. Animals thus immunized are found to be immune not only to the sarcoma concerned but also to rat carcinoma; the converse is not true. The euglobulin fraction of serum contains the anti-malignant-cell bodies. The antiserum is not effective in vivo unless it can be localized in the tumor by constriction of the part affected (leg) or by adrenalin. The mechanism of tumor immunity consists of (a) production of anti-malignant-cell bodies and (b) action of a specific cytase produced by the leucocytes.—*R. R. Spencer.*

16518. **LUNDBERG, ÅKE. De la lécithine, en tant que substance capable d'inhiber l'hémoagglutination.** *Acta Med. Scandinavica* 72(5/6): 395-398. 1929.—Group determinations were made with citrated blood, as usual. If agglutination was present, the blood was mixed with an emulsion of ovolecithin, and the group redetermined. Diluted blood was used at room temp. Dungern and Hirszfeld's nomenclature was taken. In groups A or B, no agglutination was present, after adding lecithin. Blood in group AB acted as if in group O or AB. In 3 clinical cases, helpine was substituted for ovolecithin, and injected intravenously; they were divided into groups with respect to the length of time that agglutination was inhibited. Although a preliminary report, it appears quite definite that lecithin prevents agglutination in vitro and slows it down in vivo.—*J. E. Andes.*

16519. **MOLONEY, P. J., and EDITH M. TAYLOR. Effect of certain oxidation-reduction potential indicators on diphtheria toxin.** *Trans. Roy. Soc. Canada, Sect. 5. Biol. Sci.* 24(1): 127-132. 1930.—Diphtheria toxin may be rendered atoxic by certain of the oxidation-reduction indicators. The rate of detoxification decreases approximately in the order: 2-chlorophenol-indophenol, phenol indophenol, 1-naphthol-2-sulphonate indophenol, methylene blue, indigo tetrasulphonate and indigo disulphonate. The evidence supports the view that oxidation is a factor in detoxification. The rate of detoxification increases with increased concentration of indicator and with increased alkalinity of solution, at pH 6.5-7.5. By certain of the indicators, toxoids may be produced, which are equal antigenically to those produced by the action of formalin on toxin. As good antigens have been produced from purified toxin by formalin action as from crude toxin of the same combining value. Toxoid made by 1-naphthol-2-sulphonate indophenol has a markedly lower value than that produced by the other indophenols used.—*B. Cohen.*

16520. **MOORE, MARJORIE B., and EDMOND E. MOORE. Studies on pollen and pollen extracts. II. The adsorption of allergically active constituents from pollen extracts.** *Jour. Allergy* 2(3): 168-172. 1931.—The efficiency of 5 adsorbents for solid materials and for N from 2 giant ragweed [*Ambrosia trifida*] pollen extracts, was measured. The extracts were ones commonly employed for clinical desensitization, water and a buffered saline serving as extracting fluids. The same determinations were made on a water extract of timothy [*Phleum pratense*] pollen, using the 2 most efficient adsorbents tried. The activity of extracts and of filtrates after adsorption was tested: (1) by the scratch method on hay fever patients sensitive to whole pollen extract, (2) by the intradermal method in sites on normal individuals sensitized by local passive transfer, and (3) by skin tests on rabbits sensitized to whole pollen. The order of efficiency as measured by chemical means was the same as that measured by the skin-reacting activity of the filtrates after adsorption, toward man or sensitized rabbits. This order was: active charcoal, Fe oxide and alumina gel, diatomaceous silica and silica gel.

The last 2 adsorbents appeared to cause no decrease in activity of the extracts.—*Author's summary.*

16521. **NEILL, JAMES M., WILLIAM L. FLEMING, JOHN Y. SUGG, ROY C. AVERY, LURLINE V. RICHARDSON, and BERNARD E. KANE. Hypersensitiveness to diphtheria bacterial products. Comparison of filtrates of highly and of weakly toxicogenic strains.** *Jour. Immunol.* 18 (6): 437-454. 1930.—The hypersensitive man (individual-C) previously reported reactive with toxin-containing and non-reactive with non-toxin-containing test materials, was studied further by comparison of the hypersensitive reactivity or non-reactivity of the filtrates of highly and of weakly toxicogenic strains of diphtheria bacilli. With a constant test dose (3.0×10^{-4} cc.) of filtrate, each of 18 highly toxicogenic strains produced a moderate to strong immediate skin reaction; none of 14 weakly toxicogenic strains gave any reaction. This sharp demarcation was acceptable proof that the agent of this man's hypersensitive reaction was consistently present in higher concentration in the filtrates of highly toxicogenic, than in the filtrates of weakly toxicogenic, strains. While the evidence is of indirect nature, it strongly suggests that diphtheria toxin is the substance involved in the hypersensitive immediate skin reaction described.—*J. M. Neill.*

16522. **NEILL, JAMES M., WILLIAM L. FLEMING, JOHN Y. SUGG, and E. L. GASPARI. Hypersensitiveness to diphtheria bacterial products. Prevention of hypersensitive reactions by neutralization of the toxin previous to intradermal injection.** *Jour. Immunol.* 18 (6): 455-472. 1930.—Previous evidence indicative that toxin is the substance involved in individual C's hypersensitiveness was based on the consistent association of high toxin content of test material with high degree of hypersensitive reactivity and of low or no toxin content with weak or no hypersensitive reactivity. The evidence here is based on the constant association between antitoxin content of serum and capacity of serum to neutralize the hypersensitive agent when the toxin-containing filtrate is incubated with the serum before intradermal test injections. Experiments with similar results were obtained with antitoxin-containing serum of horse, rabbit, and man. The most convincing results were obtained with human sera because it was possible by choice from a large number to select more purely "antitoxic" sera than could be obtained by laboratory immunization of animals. The selected human sera, containing antitoxin but no precipitins and only traces of "group agglutinin" or none, were able to neutralize the agent of the hypersensitive reaction. Further experiments demonstrated a quantitative relationship between antitoxin content and amount of the respective serum required to neutralize the substance hypersensitively reactive with individual C.—*J. M. Neill.*

16523. **NEILL, JAMES M., JOHN Y. SUGG, and LURLINE V. RICHARDSON. Hypersensitiveness to diphtheria bacterial products. Anaphylactic reactions of antitoxin immune guinea pigs.** *Jour. Immunol.* 19 (2): 109-143. 1930.—The paper reports the anaphylactic reactions of guinea pigs immunized with toxoid and subsequently injected intravenously either with phenolized filtrate containing toxin antigen, or with formolized filtrate containing toxoid antigen. It was proved that the acute death of the antitoxic-immune animals represented true anaphylactic reactions specific to bacterial products contained in diphtheria filtrate. While it was recognized that other constituents participate to some extent, the evidence as a whole indicates that toxin or toxoid antigen is the principal agent of the anaphylactic reaction of antitoxic-immune guinea pigs to unheated filtrates containing a relatively large proportion of toxin or toxoid. The complications due to substances other than toxin or toxoid are least prominent if one uses both for immunization and for the intravenous test, minimal amounts of unheated filtrate in which toxoid is the dominant antigen, and finally selects for intravenous test, individual guinea pigs that have been "earliest" in antitoxin production.—*J. M. Neill.*

16524. **PLAUT, F. Serologie der Lipoide in ihrer Beziehung zur Syphilis und Metasyphilis.** *Zeitschr. Ges. Neurol. u. Psychiat.* 123 (2/3): 365-390. 1929.—The author critically reviews the experimental findings of various workers in their attempts to produce lipoid antibodies. Results with pure lipoid preparations, lipoid conjugated with protein, extracts of bacteria, extracts of *spirocheta pallida* and organ extracts are compared as to antisera produced by their injection into animals. Special stress is laid on the variety of responses of different experimental animals—rabbits, e.g., being most susceptible to immunization with organ extracts.—*Pearl L. Kendrick.*

16525. **PRATI, MARIO. Der Einfluss der Mikroorganismen auf die Hämagglutination.** *Zeitschr. Immunitätsforsch. u. Exp. Therapeut.* 57 (1/2): 1-18. 3 fig. 1928.—Pseudoagglutination observed in an ab serum contaminated with bacteria led to an experimental study of artificially inoculated sera. The following organisms all caused pseudoagglutination after varying periods of incubation in ab serum: staphylococci, streptococci, *Bacillus pyocyaneus, B. subtilis, B. anthracis, B. tuberculosis, B. paratyphosus, B. typhosus, B. melitensis, B. coli.* Pseudoagglutination was extremely hard to differentiate from true isoagglutination. The substance causing it was associated with change in the proteins of the serum, and the author correlates it with the same changes which cause increased sedimentation rate in infections. Pseudoagglutination does not interfere with true isoagglutination and resembles rouleaux formation, but is nevertheless difficult to differentiate.—*C. M. Downs.*

16526. **RAI, T. Immunologische Beobachtungen beim Rekurrens des Kaninchens. I, II, III.** [In Japanese, with German summary.] *Acta Dermatol.* 17 (5): 356-373; (6): 413-426; 427-452. 1931.—I. The appearance of antibodies against relapsing fever in rabbits was studied by mixing sera of infected rabbits in serial dilutions, with mouse blood containing spirochaetes, incubating the mixture, and inoculating mice. Serum of infected rabbits during onset and crisis did not differ in action from normal serum; antibodies were first apparent about 24 hrs. after crisis. The author infers that antibodies originate during onset and crisis, but are imperceptible because occurring in relatively small numbers and absorbed by the antigen (spirochaetes in the circulating blood).—II. Active and passive immunity against relapsing fever were induced in rabbits. Intravenous injection of a suspension of relapsing fever spirochaetes, sterilized for 30 min. at 56° C., induced immunity which was slight 24 hrs. after inoculation, rather strong after 48 hrs., and very marked after 72 hrs., rapidity of increase being in proportion to amount of antigen inoculated. Immune serum from infected rabbits induced in a healthy rabbit a very marked immunity within 6 hrs., degree of immunity being in proportion to dose of serum.—III. The immunity induced in a rabbit by infection with relapsing fever increased rapidly for 2 wks., and generally decreased suddenly after 3-4 wks. and gradually after 5 wks. The sera of severely infected rabbits were strongly and lastingly immune; those of lightly infected rabbits were weak and transiently immune.—*From author's summary.*

16527. **RAMON, G., A. BESSEMANS, et F. de POTTER. Le développement des anticorps au cours de l'immunisation du cheval par divers antigènes diphthériques.** *Compt. Rend. Soc. Biol.* 106 (12): 1104-1107. 1931.—An emulsion of living diphtheria bacilli and later, toxin, were injected under the skin of 2 horses and, in the same way, 3 other horses received living diphtheroids (ozena strain) or bacteria isolated recently from a case of diphtheria. 2 horses, one of which was hyperimmunized with anatoxin, were injected intravenously with living bacteria. In every case the doses were gradually increased over a period of 1 mo. or more. The animals were bled generally before each new injection of antigen and the sera tested for antitoxin, agglutinin and for antibodies fixing complement. The subcutaneous injections produced increasing amounts of antitoxin, except in the horse which received diphtheroids, where there was none.

All these sera were negative when tested for agglutinin. Intravenous injection of bacteria resulted in quick production of agglutinin which reached its maximum after the 2nd injection. The amount of antitoxin decreased more rapidly in the hyperimmunized horse. The amount of complement-fixing antibody varied from one animal to another. When bacteria are introduced subcutaneously, they grow at the site of injection and produce toxin which is then introduced into the blood stream and gives rise to formation of antitoxin, but not to agglutinin. Intravenous injection causes a quick production of agglutinins, but, since the blood stream is unfavorable for growth of the bacteria, no toxin is produced and the amount of antitoxin formed soon reaches its maximum value. This upholds the theory of the authors, that antigen or its direct derivatives enter into the constitution of antibody.—*E. Weiner.*

16528. ROWE, ALBERT H. Food allergy. Its manifestations, diagnosis and treatment, with a general discussion of bronchial asthma. xi+442p. Lea & Febiger: Philadelphia, 1931.—Price $5.00.—Food allergy is a term used to denote changes in the human organism from a hypersensitiveness of the body cells to specific foods. "The active principle in foods to which hypersensitiveness is established in the body cell is probably a protein or some substance, such as a ferment closely bound up with the protein molecule." The author's experience, together with observations of others, indicate that food allergy is a common cause of human symptomatology. It may produce localized symptoms in any tissue or part of the body, especially in the gastro-intestinal tract. This monograph discusses food allergy from the clinical, experimental, diagnostic, therapeutic and historical viewpoints. Case histories, experimental investigations and a study of results obtained by the author's "elimination diets" are presented in detail. The book is divided into 15 chapters: Food Allergy: its occurrence and characteristics; Diagnosis of food allergy; Treatment by elimination diets and general measures; Gastrointestinal food allergy; Bronchial asthma; Eczema, urticaria, angioneurotic edema and generalized edema; Allergic migraine and neuralgia; Allergic toxemia due to food allergy; Perennial hay fever; Arthritis, arthralgia, intermittent hydrarthrosis, dysmenorrhoea, cardiovascular disturbances, Henoch's purpura; Bladder allergy; Nervous manifestations of food allergy; Food allergy in infancy and childhood; General considerations in regard to food allergy; Individual food allergies and their control; Summary of literature on food allergy.—*S. Bayne-Jones.*

16529. SCHÖBL, OTTO. The immunologic effect of repeated yaws infections interrupted by specific treatment given in the early stage of initial yaw. *Philippine Jour. Sci.* 43(4): 589-594. 1930.—Repeated local yaws infections terminated by specific treatment given before the time when generalized yaws manifestations occur, produce immunity in Philippine monkeys, even though delayed. The incubation period becomes irregular, mostly prolonged with repeated reinoculations terminated by treatments. This shows that the developing immunity, although not yet strong enough to suppress completely the development of lesions, has a definite effect on the incubation period. This observation strengthens the claim that sensitization is the underlying principle of immunity in treponematoses. The findings on monkeys corroborate and amplify previous findings on human volunteers and prove that immunization against yaws by repeated local yaws infections terminated by treatments is possible. Jointly with the author's previous experimental evidence, these results indicate that the most favorable time for immunization in treponematoses is the early stage of infection and that it must be carried out vigorously within the first few mo. of infection or immunization.—*Author's summary.*

16530. SCHÜTZ, FRANZ, und F. v. HUTYRA. Über die experimentelle Grundlage der Schutzimpfung gegen Tuberkulose nach Calmette. *Zeitschr. Immunitätsforsch.* 62(1/2): 74-106. 3 pl. 1929.—BCG, though a greatly weakened strain, is still not completely avirulent for guinea pigs. At times it may cause, in undernourished animals, typical, progressive, and even fatal generalized tuberculosis. In some instances the disease so produced can be transferred to other animals and the "virus" may attain a high degree of virulence by such animal passage. The individual resistance of the animal plays an important rôle in eliciting the pathogenic capacity of the vaccine. Guinea pigs which have not been made ill by the vaccine withstand thereafter an inoculation of a moderate dose of bovine tubercle bacilli.—*M. B. Lurie.*

16531. SEWALL, HENRY. Psychic analogues of allergy. *Science* 74(1906): 37-39. 1931.—"Allergy" implies a defensive reaction against a particular antigen in a prepared subject. It is manifested by more or less violent inflammation, doubtless associated with specific chemical changes. This may be either conservative or destructive for an infected host. But sudden amelioration in the course of disease so frequently follows acute allergic disturbance that immunologists generally have come to regard allergy as itself the protective agency against infection and the concomitant of immunity. Against this view A. R. Rich has recently opposed apposite objections the resultant of which is that allergy as such has no place in the chain of events leading to immunity and that the good or harm it may do is accidental. To the writer it has seemed plausible that all these views may be too narrow. Protective reactions against viable enemies must have been primordial, independent of specific chemistry or mechanism. We find obvious analogues in the psychic sphere. Thus, the sense of pain, and the emotion of fear, wholly extra-physiological as they are, nevertheless are reactions conservative of life. The feeling of national spirit unites communities for mutual defense. Like allergy, these powers in certain intensity and coordination, protective to the host, may, uncontrolled, destroy him.—*H. Sewall.*

16532. SHIBATA, JUNICHIRO. Untersuchungen über die Komplementbindungs- und Tuberkulinreaktion mit dem BCG-Stamm im Vergleiche zu einem virulenten Tuberkulosestamm. *Zeitschr. Immunitätsforsch.* 63(5/6): 358-370. 1929.—Immune sera of a BCG strain and of a virulent bovine strain (Vallée), prepared by inoculating rabbits with dead culture suspensions, reacted equally in complement fixation tests with suspensions of the 2 strains. When alcoholic extracts of the strains were employed as antigens, inhibition of lysis with both immune sera was as pronounced as with intact bacilli, and similarly without specificity for the homologous strain. Immune sera obtained by inoculation of rabbits with alcoholic extracts also reacted equally in complement fixation tests with alcoholic extracts, but not with intact bacilli, used as antigens. After reciprocal absorption of immune sera with their respective bacilli, complement fixation in presence of either antigen was unchanged. Both immune sera in large doses inhibited hemolysis in complement fixation tests with the following antigens: alcoholic extract of ox heart and, to a less extent, aqueous and alcoholic extracts of brain, liver, and kidney of rabbits; and no definite difference in the strength of the reaction was perceptible with these, or with the tubercle bacillus antigens. No difference was manifest in amount of reaction in intracutaneous inoculations performed with tuberculins prepared with the 2 strains, on guinea pigs infected with the Vallée strain; but when the lethal effect of these tuberculins was tested by subcutaneous injection of larger doses into infected guinea pigs, the tuberculin of the BCG strain was clearly less toxic than that of the Vallée strain.—*R. T. Hewlett.*

16533. STOELS, G. Culture in vitro di vitro [virus] vaccinal et immunité antivaccinale. *Arch. Exp. Zellforsch. Bes. Gewebezücht. (Explantation.)* 10(4): 452-462. 1931.—Neurovaccine was added to embryo extract in Borrel flasks, 1-2 mm. fragments of rabbit spleen or testis, embryonic chick, or Rous chicken sarcoma were added, and a few min. later plasma. In controls the vaccine disappeared in 4 days at 37°, showing the necessity of living cells for in vitro culture; in their presence it lived and increased. Inclusions resembling Guarnieri bodies ap-

peared only in cultures of embryonic cornea, but must be regarded as signs of degeneration, since they appeared also in the controls. Cultures of rabbit spleen or testis were used to test antivaccinal immunity, using tissue or plasma from previously vaccinated animals. Using "immune plasma" with normal tissue, the cultures were no more virulent after 4 days at 37° than were controls (plasma added after 5 min.). A series was made in which immune plasma was added only after 5, 15, 30, and 90 min., giving time for the virus to penetrate the tissue, and the cultures were tested after 5 hrs.; the 1st had almost no virulence, the 2nd some, the 3rd and 4th a great deal. "Immune" spleen cultures destroyed large doses of virus within 5 hrs.; those of the testis were slightly virulent after 5 hrs. and virulence increased progressively after the next day. This was undoubtedly owing to difference in the cells: in the spleen, leucocytes, lymphocytes and macrophages; in the testis, fibroblasts and a few macrophages. The hypothesis that the leucocytes, macrophages, and in general all cells of the reticulo-endothelial system, have a cellular, antivaccinal immunity which the fibroblasts do not have, would explain this.

16534. **STRAUS, HENRY W. Artificial sensitization of infants to poison ivy.** *Jour. Allergy* 2(3): 137-144. 1931.—A poison ivy paste, applied as a patch test to 41 normal and atopic adults, gave a positive test in 75.6%. The same material applied to the skin of 119 newborn with the same technique gave 100% negative results. After 2-4 wk., 48 of the infants were retested by the patch method and a positive reaction was obtained in 72.9%. The skin was generally sensitized. The insusceptibility heretofore observed in children under 3 yrs. is not due to lack of mechanism, as formerly believed, but to lack of previous, or of sufficient, contact.—*H. W. Straus.*

16535. **SUGG, JOHN Y., and JAMES M. NEILL. Use of broth culture filtrates in anaphylaxis experiments.** *Jour. Immunol.* 19(2): 145-153. 1930.—The primarily toxic (anaphylactoid) action was studied by intravenous injection of normal guinea pigs with formolized and unformolized filtrates of diphtheria and other bacilli and with the non-bacterial constituents of the filtrates (uninoculated broth, solutions of phenol and of formol). The possibility of sensitization to the non-bacterial constituents during immunization with the filtrates was studied by intravenous tests on animals previously given repeated subcutaneous injections of formol solution or of formolized broth. With diphtheria filtrates, neither primary toxicity nor possibility of sensitization to broth constituents, introduced significant complications in their use as material for active sensitization and for subsequent intravenous tests. The adaptability of broth culture filtrates of other bacteria to anaphylaxis experiments would depend on the quantitative effectiveness of the antigens they liberate into their culture fluids.—*J. M. Neill.*

16536. **TAYLOR, G. L. The results of some quantitative experiments on the serum precipitation reaction.** *Jour. Hyg.* 31(1): 56-83. 1931.—Experiments based largely on the work of Dean and Webb lead to these conclusions: In the serum precipitation reaction, antigen and antibody react in equivalent proportions to form an antigen-antibody complex which adsorbs suitable matter from the surrounding medium. Excess antigen is adsorbed by, and exercises a protective action on, the micellae of the complex, and prevents completion of the reaction. Antibody in excess does not affect the reaction, but in the great majority of cases is traceable in the supernatant fluid, in equivalent amount. The speed of particulation depends on the amount of complex and adsorbable matter present. There is some evidence that in certain cases the nature and quantity of adsorbable matter may be such as to cause excess of antibody to be removed from the supernatant fluid. In such cases the adsorbable matter may possibly be adsorbent to the excess of antibody. Antisera vary in amount of antibody and in amount and nature of adsorbable matter contained. Addition of adsorbable matter is a useful way of hastening and facilitating the reading of reactions.

16537. **THIELE, HEINRICH. Diphtherieschutzimpfungen, Schickprüfungen und Bestimmungen des Antitoxin-Titers im Serum.** *Arch. Kinderheilk.* 94(2/3): 175-202. 1931.—Of 337 school-age children tested for diphtheria sensitivity, 103 were Schick-positive, girls and younger children being more affected. In about 20%, Schick test and antitoxin titer failed to correspond, due to limited possibilities of comparison between Schick and Römer (R) reactions, inadequacy of present Schick preparations, abnormal behavior of some children, and errors in observation. Numerous exceptions were observed. Of 31 pairs of siblings, 27 showed similar reactions. Of the inoculation preparations—T.A.F.-Behring, anatoxin-Behring, toxoid-Löwenstein, and anatoxin Ramon—the last was most dependable and effective.

16538. **THOMSEN, OLUF. Om eksistensen af blodtyper (blodgrupper), sideordnede og underordnede de fire Landsteiner'ske typer. [Existence of blood-types (blood-groups) beside and below the four Landsteiner groups.]** *Hospitalstidende [Copenhagen]* 71(11): 253-272. 1928.—A critical examination of the numerous "subgroups" found by different researchers and based on the agglutinability of the erythrocytes of certain individuals in sera of isolated individuals outside the "4-group-scheme." Most of these agglutination phenomena are due to the action of more or less irregularly appearing "cold-agglutinins." A constant classification into sub-groups on this basis can hardly be carried into effect.—*O. Thomsen.*

16539. **THOMSEN, OLUF. Om Blodlegemernes Receptorudvikling hos Nyfødte og spaede Børn. [Receptor development of the blood-corpuscles in the newborn and in infants.]** *Hospitalstidende [Copenhagen]* 71(28): 743-753. 1928.—Particularly in the newborn of AB-group, the A-receptor is in many cases but slightly developed, in some cases even so little that only with the help of very strong iso-sera (titer 500 or more) or of immune sera, is it possible to detect the A-receptor. Hence, a very weak A-receptor may be misinterpreted as O. The weak development of A in some AB-individuals may be interpreted as a relative dominance of B over A, which thus tends to corroborate the supposition that A and B are allelomorphic genes (Bernstein). The weakest A-receptor is found in the A_2B-group.—*O. Thomsen.*

16540. **THOMSEN, OLUF, og AXEL THISTED. Undersøgelser over Isohaemolysin i Menneskeserum. [Isohemolysis in human serum.]** *Hospitalstidende [Copenhagen]* 71(51): 1367-1379. 1928.—By using erythrocytes which had been standing at 0° C. for 1-4 days, all human sera proved to contain both isolysin and agglutinin (Hesser). The hemolysin is of a complex nature and, after previous inactivation (55°), can be partly reactivated. Examination of fresh human serum (at most, 2 hrs. after drawing) proved that fresh erythrocytes are also hemolyzable. A-erythrocytes hemolyzed much more frequently (in sera of O- and B-groups) than B-erythrocytes (in sera of O- and A-groups). Hence, it is questionable to use group-O as a universal donor, particularly for transfer to individuals of A-group, and, notably, if the donor's hemolysin titer be high.—*O. Thomsen.*

16541. **TOMÁSEK, VÁCLAV. O významu extraktu při Bordet-Wassermannově reakci. Nový extrakt pro BWaR, jeho podstata a praktická cena. [Importance of antigen in the Bordet-Wassermann reaction. Principles and practical value of a new antigen.]** [With French summary.] *Spisy Lékařské Fak. Masarykovy Univ. Brno (Publ. Fac. Med. Brno)* 6(53): 5-40. 1928.—A very active antigen for the Bordet-Wassermann reaction may be prepared from coagulated ox serum treated with a liquefying bacillus. 5-10 tubes of coagulated serum are inoculated with *B. pyocyaneus* and incubated for 5-7 days. The liquid is then decanted into a dish and dried in the incubator for some days. The dry material is ground and 1.0 gm. of the fine powder is extracted with 40 cc. of absolute alcohol for 10 days at 37°C., shak-

ing several times a day. For use, 1 cc. of alcoholic extract is diluted drop by drop with saline to make a 1:15 dilution, when the test is done at 37°; or a 1:25 dilution, when the test is done in the ice box for 12 hrs., followed by 1 hr. at 37°. For an active and sensitive antigen, dilutions must be made very slowly. Other proteolytic organisms may be substituted, but pathogenic forms should not be used. The combined lipoids of the serum set free by proteolysis are the active agents, rather than the free lipoids of the serum, for broth and agar cultures of *B. pyocyaneus* only exceptionally react, and alcoholic extracts of untreated serum, never. The active lipoids can not be extracted from serum with ether, and an antigen prepared by the *B. pyocyaneus* method from a protein poor in lipoids is inactive. Peptic digestion of serum yields an inactive, tryptic digestion a feebly antigenic, product. Results of the Bordet-Wassermann with this *B. pyocyaneus* antigen are very encouraging. The anti-complimentary action of the extract is a little greater than with other antigens, but this can be compensated for by a larger dose of complement. It is stable and the antigenic power is marked. Non-specific reactions are less frequent when the mixtures are first treated in the ice-box and then incubated, than when they are incubated immediately.—*R. T. Hewlett.*

16543. VALTIS, J., et F. van DEINSE. Le BCG peut-il devenir virulent par culture sur filtrats tuberculeux? *Compt. Rend. Soc. Biol.* 106(12): 1109-1111. 1931.—BCG was cultured on filtrates of a virulent human strain of tubercle bacillus; 6 subcultures were made, each of which was injected subcutaneously or intraperitoneally into 2 or more guinea pigs. The guinea pigs injected with the 5th subculture died of an intercurrent malady several days afterward. None of the inoculated animals showed tuberculous lesions or bacilli in the ganglia, on postmortem. Only 2 of the animals responded positively to tuberculin. The filtrate does not increase the virulence of BCG nor does the latter increase that of the filtrate, when both are cultured together. Therefore, BCG may be used for immunizing infants of tuberculous mothers. —*E. Weiner.*

16544. VAUGHAN, WARREN T. Food allergens. II. Trial diets in the elimination of allergenic foods. *Jour. Immunol.* 20(4): 313-332. 1931.—A certain proportion of allergic individuals sensitive to foods fail to give positive skin reactions. In these cases, trial diets are formulated, containing foods known to be infrequently allergenic. The author's genetic classification of possible allergenic foods into biologic groups is the basis for his trial diets. Where a positive skin reaction to a food has been observed, the trial diet should not contain this, or any closely related, food. Wheat, egg, milk, chocolate, cabbage, orange, potato and legumes are the most frequently allergenic foods. If relief is obtained with the trial diet, new foods are added, 1 at a time, their order being based on biologic relationships. Tables show the author's genetic classification of vegetable foods, the frequency of positive reactions to various foods, and describe the formulation of the trial diet.—*W. T. Vaughan.*

16545. WHARTON, D. R. A. The effects of certain toxic substances on the ciliated epithelium of the guinea pig. *Amer. Jour. Hyg.* 14(1): 109-129. 1931.—The ciliated cells from the trachea of freshly killed normal guinea pigs, observed in dark field illumination under high power, were vigorously active, and appeared to retain their activity after several hrs. in Ringer's solution or in a variety of sera. Bacterial poisons, light and certain other factors inhibited ciliary movement, whereas bacterial toxins and venom had no demonstrable effect. The inhibitory factors of the bacterial cultures (poisons) are considered to be of protein origin. Antigen failed to produce on the ciliated epithelium of sensitized guinea pigs and on ciliated epithelium treated with precipitating antisera, any change in the action of the cilia which might be used as a criterion of hypersensitiveness or immunity. The cilia were inhibited in different periods of time by various sputa, and it is suggested that the sputum in certain respiratory conditions, as bronchitis, may affect the movement of cilia adversely.

16546. WOLFF, L. K., und G. RAS. Über unspezifische Therapie. II. *Zeitschr. Ges. Exp. Med.* 75(5, 6): 719-736. 1931.—Intravenous injections into rabbits, of 12 inorganic salts, 31 organic compounds, 12 proteins (serum or milk), 14 suspensions, and 12 samples of dead bacteria showed that a non-specific bactericidal action was obtained from all substances tried, the time between injection and effect varying with amount injected. Tolerance to histamine produced tolerance to all others; tolerance to India ink gave tolerance to all materials tested except histamine. Tolerance to a gram-negative bacterial vaccine gave tolerance for all other gram-negative, but not for gram-positive, vaccines; the reverse was also true. Subcutaneous injection also gave a bactericidal effect. The non-specific bactericidal action failed to occur in uncoagulated blood, blood and serum attaining bactericidal properties only by destruction of leucocytes. The property appeared immediately after addition of bacteria to blood. Specific bactericidal powers, inherited or acquired, occurred in uncoagulated blood, for which uninjured leucocytes were necessary; this occurred only ½-2 hrs. after mixing blood and bacteria. Serum and plasma of such blood never had bactericidal powers.

16547. YANG, K., and MAX THEILER. The relationship of Leptospira icterohaemorrhagiae and the Akiyami type A strain of Leptospira as determined by cross immunization experiments in guinea pigs. *Amer. Jour. Trop. Med.* 10(6): 407-418. 1930.—The strain of *L. icterohaemorrhagiae* used was isolated in 1925 from rats trapped in the Boston market, that of *L. hebdomadis* was the A-type isolated from akiyami, a Japanese infectious fever; virulence of both had been maintained by guinea-pig passage. For immunization, 6 guinea pigs were injected with blood of an animal with *L. icterohaemorrhagiae* infection, and 6 were injected with passage virus (2) or with culture (4) of the akiyami strain, followed in each case 24-48 hrs. later by a dose of corresponding immune serum to abort infection and preserve the animals. Some weeks later, the immunity of each group against homologous virus was tested by injection of liver pulp of a passage animal, the inoculum containing 1000-10,000 lethal doses of the corresponding virus; all animals survived. For the cross-immunity tests, the 6 icterohaemorrhagiae-immune animals were inoculated intraperitoneally with liver pulp of an akiyami passage animal, together with 6 control guinea pigs with various dilutions of the same virus material. All immunized animals lived (except one which died under an anaesthetic), whereas controls inoculated with 1/10-1/10,000 of the test dose of virus died. The 6 akiyami immune animals were similarly inoculated with massive doses of liver of an icterohaemorrhagiae passage animal and, with 1 exception, all survived, whereas 6 controls all succumbed, even with 1/1,000,000 of the test dose of virus. The 2 strains of *Leptospira* are therefore indistinguishable by cross-immunity tests, and the question is raised whether the establishment of a number of different *Leptospira* spp. is justified.—*R. T. Hewlett.*

16548. YOSHIDA, S. Immunitätsforschung der Spirochaetenkrh. V. Der Spirochaetennachweis im kreisenden Blute von gegen Rattenbisskrh. immunisierten Kaninchen nach der intravenösen Injektion der Rattenbissspirochaeten-suspension. [Japanese, with German summary.] *Acta Dermatol.* 17(1): 39-56. 2 fig. 1931.—V. [A]. Healthy rabbits (apparently 3) were intravenously inoculated with rat-bite fever spirochaetes. To determine how long living spirochaetes circulate in the blood, 0.1-1 cc. of blood was withdrawn at intervals of 3 hrs. to 11 days and injected into other healthy rabbits. Chancres were produced by blood injected on the 11th day after the donor's infection. [B]. Rabbits infected with the

spirochaetes were treated with salvarsan, and intravenously reinfected about 1 mo. after treatment. Blood withdrawn at various times after reinfection was injected into other healthy rabbits, producing primary lesions. [C]. Immunized rabbits were intravenously injected with emulsion of the spirochaetes. Blood withdrawn from them and injected under the dorsal skin of other healthy rabbits produced practically no primary lesion at point of injection. The spirochaetes disappeared from the blood of immunized rabbits much more rapidly than from that of the non-immunized. Yet the immunity was not absolute: a few spirochaetes were found in the blood of "immunized" rabbits a week after intravenous injection; and they gradually increased, becoming numerous at the end of 2 wk., eventually producing rat-bite fever. Injected into healthy rabbits, the spirochaetes increased almost from the start.—*From author's summary.*

LOWER ANIMALS

16549. **DALLING, T. Canine distemper immunization. Use of various prophylactics in hunting packs.** *Vet. Jour.* 87 (12) : 553-558. 1931.—Field trials covering several hundred hounds are reported, in which immunization was attempted by 3 methods. 2 doses of vaccine were classified as giving good results in 8 packs, as moderately good in 5, and as bad in 6. Serum and virus often gave a severe reaction which required further administration of the hyper-immune serum. Of 34 packs in which it was used, 22 were classified as good, 8 as moderately good, and 4 as bad. Vaccine followed in 14 days with dried, active virus used on 1,025 hounds gave good results in 99%.—*I. E. Newsom.*

16550. **EDWARDS, J. T. Rinderpest: Some points in immunity.** *Far East Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 707-717. 1927[1928].—By the serum-simultaneous method of immunization, young calves may acquire a solid immunity against rinderpest virus, which lasts for 2 yrs. A hyperimmune serum used in the inoculation may be made by repeated injections, but it has no special advantages over one made by a single injection, provided a mild but decided reaction is evoked. After immunity has lapsed it may be "freshened" up by inoculation of virus alone. Following Madsen's technique, injection of certain salts 2 hrs. before bleeding seemed to yield a better serum in animals already yielding a good serum, but did not increase the quality when the animals were yielding a poor serum.—*R. R. Spencer.*

16551. **FERREIRA, A. AGUEDA, et T. SÁ VIANA CONTE. Recherches des substances rabicides dans le sang des chiens vaccinés contre la rage.** *Arq. Inst. Bact. Camara Pestana* 6 (2) : xxvii-l. 1930.—The authors vaccinated 2 lots of dogs against rabies, one with avirulent vaccine and another with virulent vaccine, remarking that the viricidal power of the blood was positive in the first lot in 42% at the 10th to 19th days, and in only 28% at the 30th to 50th days. In the 2nd lot the averages were, respectively, 52% and 62%. When these vaccinated animals were inoculated with street virus, 57% of the 1st lot of dogs developed rabies and only 31% of the 2nd lot. Protection of the animals was paralleled by the presence of viricidal substance in the serum.—*A. A. Ferreira.*

16552. **FINZI, G. Tubercoline e anaesotubercoline.** *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 12 (11) : 605-612. 1930.—Discussion of additional experiments convincing the author of the superiority of his tuberculin for diagnosis in cattle.—*P. Popenoe.*

16553. **FINZI, GUIDO. Il B. C. G. nella profilassi della tuberculosi bovina.** *Profilassi* 10: (1-82). 1931.—A résumé of the literature against BCG vaccine for veterinary use.—*F. W. Fornet.*

16554. **FREIRE MUÑOZ, CARLOS. La vacuna antirrábica de los perros por el método de Umeno y Doi. [Prevention of canine rabies by the method of Umeno and Doi.]** *An. Escuela Vet. Uruguay* 1 (12) : 457-466. 1929.—Both prevention and cure of experimental rabies of dogs proved successful by subcutaneous inoculation of phenolized-glycerolized rabic virus which had been previously kept for 7 days at 37° C. Exposures for 30 days in the ice-box or for 15 days at room temp. proved inadequate for a reliable loss of virulence. 3-5 cc. of the Umeno-Doi vaccine prepared as above protected dogs against further inoculations of street-virus by ocular route in an average of 83.33% of cases; only 25% of control dogs were spared. Curative results could also be obtained in dogs which had been previously bitten by typically rabic dogs even after 7 days, by Umeno-Doi vaccine injected subcutaneously in doses of 3-5 cc.—*A. de Assis (from author's abstract).*

16555. **FRÖHLICH, R. Erfahrungen bei der Bekämpfung des seuchenhaften Abortus.** *Tierärztl. Rundschau* 37 (33) : 588-592. 1931.—Animals which show no symptoms, either clinically or in history of abortions, frequently give positive agglutination tests for *B. abortus.* Injections of a vaccine into such animals have always insured successful gestation. Infection of man through the milk has never been observed.—*R. Fröhlich (transl. by L. C. Havens).*

16556. **HAMEDY, A. Le phénomène de l'iso-agglutination chez les chevaux avant et après leur hyperimmunisation antitoxique.** *Compt. Rend. Soc. Biol.* 106 (12) : 1095-1097. 1931.—The blood of 33 horses, divided into groups of 11 each, was examined before the beginning of anti-diphtheria immunization with increasing doses of anatoxin and after completion of hyperimmunization, 2 mo. after the first examination. The amount of iso-agglutinin in the blood of horses is very small, making the phenomena of isoagglutination less clear than in man. Variations in the blood groups of some of the horses was caused by hyperimmunization. Results of the Schick test had no direct relation to blood groups.—*E. Weiner.*

16557. **HOWARTH, J. A., and F. M. HAYES. Brucelliasis in the swine herd of the University of California.** *Jour. Amer. Vet. Med. Assoc.* 31 (6) : 830-848. 3 fig. 1931.—Agglutination tests of the blood serum of all swine in the herd failed to control spread of *Brucella* infection, when accompanied by removal of reactors, until the frequency of tests was increased to 2-wk. intervals. As measured by the agglutination test, agglutinins for *Brucella* varied markedly in concentration in reacting swine that were repeatedly tested and usually did not appear in dilutions of 1: 400 and above. Offspring from reacting sows became reactors after receiving colostrum, but soon became negative and remained so, although in intimate contact with infected mothers, until approximately 3 mo. after weaning. Abortions and birth of dead pigs were not significant symptoms, since reacting sows farrowed 2.64% and negative sows, 2.21%, of dead pigs. 1 negative cow exposed to infected swine became a reactor on the 91st day.—*F. M. Hayes.*

16558. **LAGRANGE, E. Sur l'autostérilisation mortelle des poules vaccinées contre la peste aviaire d'Egypte.** *Compt. Rend. Soc. Biol.* 106 (12) : 1080-1081.—In vaccinating chickens against Egyptian bird plague, some always succumbed; in these, the spleen, liver and blood were avirulent, while the brain was always virulent. Post-mortems of unvaccinated chickens which died of spontaneous or experimental infection showed autosterilization of the brain, while the abdominal viscera were virulent. The non-virulence of the brain in unvaccinated chickens is ascribed to an epidemic or seasonal factor, while mortal sterilization in vaccinated chickens is produced independently of seasonal factors.—*E. Weiner.*

16559. **ROSSI, PAUL. Antivirusthérapie.** *Rev. Vét. et Jour. Méd. Vét. et Zootech.* 83 (July) : 361-380. 1931. —Antivirus therapy, preventive or curative, is based on local application of substances derived from bacteria, without addition of antibodies. These antiviruses act specifically on the "receptive" cells for which the bacteria show a special affinity—a true tropism. They are incapable of affecting cells already injured, but protect those still unchanged and surround the focus of infection, preventing those within from serving as a source of new infection. The "autoviruses" and "regional viruses" are most effective, and produce rapid local

immunity without appreciable reaction. The organisms against which antivirus therapy is most effective are staphylococci, streptococci and anthrax bacilli. There are also several conditions in veterinary medicine in which this treatment is indicated.—*P. Rossi (transl. by E. I. Parsons).*

16560. BLACKIE, W. K. Observations on the immunity response in experimental ascaridiasis in rabbits. *Jour. Helminthol.* 9(2): 91-96. 1931.—Experiments showed that during the migratory phase of the life-cycle of *Ascaris megalocephala* a definite humoral response occurs, which is manifested in the serum of the host by the presence of specific complement-fixing antibodies. Results are suggestive of the occurrence of a definite immunity response in ascaridiasis.—*F. J. Meggitt.*

16561. KONSTANSOFF, S. W. Malariaimmunität, Malariavakzine und Vakzination. *Zentralbl. Bakt. I. Abt. Orig.* 116(4/5): 241-256. 1930.—In regions where the disease is endemic, many individuals never succumb to infection or never again manifest symptoms after attack. This is interpreted as evidence of a true immunity. A permanent cure following quinine therapy may be attributed in part to an immunity resulting from prolonged sub-acute infection. If the drug effects are rapid, development of immunity may be prevented. The autogenous vaccine used consisted of infected red cells lysed with distilled water so that the parasites were first freed and then dissolved. The immunizing value of the vaccine was proportional to number of organisms, estimated at 750,000-80,000,000 per cc. The findings of others as to the possibility of artificial cultivation of the parasites could not be confirmed. 2-5 cc. amounts were given subcutaneously at intervals of 10 hrs. to 5 days. No untoward symptoms developed. The patient's response was a lytic fall in temp. curve with prolongation of febrile period up to as much as 40 hrs. Following the fall in temp., the ratio of polynuclear to mononuclear leucocytes returned to normal. In the records of 5 cases thus treated, one showed lysis of temp. after the 3rd day; another, of long standing infection, responded only after 2 mo. of treatment. Both remained parasite-free and without clinical manifestations. Partial failure in 3 cases was attributed to poverty of vaccine in organisms and to interruption of treatment.—*S. G. Ramsdell.*

16562. MESSIK, R. E. Zur Frage der genetischen Beziehungen zwischen Leishmania tropica und Leishmania donovani. *Zeitschr. Immunitätsforsch.* 63(3/4): 327-336. 1929.—Cross serological tests were tried with 4 strains of *Leishmania;* 2 of *L. tropica* and 2 of *L. donovani.* Rieckenberg tests (thrombocytobarins), complement fixation and tests of growth in presence of immune serum show the identity of the 4 strains. The author concludes that the tests indicate the presence of common antigenic properties in all species of *Leishmania.*—*W. H. Taliaferro.*

16563. REBRASSIER, R. E., and BRYCE R. McCRORY. A study of immunity or resistance to Ascaridia lineata (Schneider). *Jour. Amer. Vet. Med. Assoc.* 32 (3): 349-358. 1931.—The immunity of chickens to *A. lineata* was studied, following immunization with saline extracts of the specific worm. A total of 141 birds were first divided into 3 groups containing those 46, 97 and 131 days old, respectively. Each group was further sub-divided into 3 lots of 16 birds each and treated as follows: Birds in lot 1 received 1 intraperitoneal injection of 1 cc. of a 5% extract of dried *A. lineata;* 4 days later lots 1 and 2 received 500 embryonated ova of *A. lineata;* birds in lot 3 received neither worm extract nor eggs. All received a standard diet. Results in each age group are consistent in showing that chickens receiving extract and ova made a greater gain in wt. than those receiving only ova, but a lower gain than controls; and that a large % of chickens receiving ova alone showed an enteritis, which was very rare in those receiving extract and ova and absent in controls receiving neither. The birds receiving ova and extract in the 46-day-old group showed more worms than those receiving only ova.—*W. H. Taliaferro.*

16564. SCHWARTZ, BENJAMIN, JOSEPH E. ALICATA, and JOHN T. LUCKER. Resistance of rats to superinfections with a nematode, Nippostrongylus muris, and an apparently similar resistance of horses to superinfection with nematodes. *Jour. Washington [D. C.] Acad. Sci.* 21(12): 259-261. 1931.—Following the recovery of rats from a single infection with *N. muris,* the host is relatively resistant to subsequent infections. In infections acquired percutaneously, the larvae migrate to the lungs and, after developing there for a time, pass into the intestine where they reach maturity in 6-7 days after infection. Rats killed 13-16 days after the 1st infection contained in the intestine fully-grown, sexually-mature worms, and occasionally a few larvae, usually 3-5, in the lungs. Rats killed 13-16 days after the 2nd infection showed many larvae in the lungs; in some cases 50% or more of the total worms present were there. Worms recovered from the intestine were, for the most part, undersized, though usually sexually mature. In investigation of the prevalence in horses of species of *Habronema,* transmitted by flies, it was noted that despite the absence of flies in winter in the vicinity of the District of Columbia, agamic forms of *Habronema* spp., in many cases no further advanced in development than that attained in their intermediate fly hosts, were found in the stomach of horses. This appears to indicate a type of resistance of horses to *Habronema* similar to that exhibited by rats to *Nippostrongylus.*—*J. E. Alicata.*

16568. **ASSENDELFT, F. van. Impfmalaria.** *Beih. Arch. Schiffs- u. Tropen-Hyg.* 35(1): 1-104. 1931.—This monograph is a critical study of the therapeutic use of malaria in cases of paresis. After an historical introduction, in which credit is given to Wagner von Jauregg as the most important pioneer in this undertaking, the author presents his own observations based on more than 350 cases in Amsterdam. Only *Plasmodium vivax* was used, since *P. falciparum* was considered to be too dangerous for experimental use. The intravenous route was found to produce a shorter prepatent period than the intramuscular one. The number of plasmodia is stated not to be the determining factor in the incubation period, but the following are important: (1) age of the plasmodia, (2) resistance of the donor and of the patient to the organisms, and (3) the possible differences in virulence of different strains. The fever and white cell curves are then considered. The former is usually quotidian (i.e., malaria duplicata); the latter, very inconstant. The curve of multiplication of the parasite is not essentially different in the three methods of inoculation, namely, mosquito infection, intravenous or subcutaneous inoculation. In addition to its therapeutic value, inoculation malaria has served an important purpose in opening a new way and developing a new point of view in the study of experimental malaria.—*E. C. Faust.*

16569. **BLASCHIN, A. N. Beobachtungen der Eier von Parasitenwürmern auf einem dunkeln oder kontrastierenden Grund.** *Arch. Schiffs- u. Tropen-Hyg.* 35(7): 363-365. 1931.—The method described permits the observer to recognize under the microscope the eggs floated on the surface of a brine solution.—*E. C. Faust.*

16571. **BUCKLEY, J. J. C. An observation on human resistance to infection with Ascaris from the pig.** *Jour. Helminthol.* 9(2): 45-46. 1931.—Migrating larvae of the pig *Ascaris* were fed to man, to a green monkey, and to 2 pigs; adult *Ascaris* were found only in the pigs. It is concluded that under normal conditions man cannot become infected with this species.—*F. J. Meggitt.*

16572. **CAMERON, THOMAS W. M. Experimental infection of sheep with Dicrocoelium dendriticum.** *Jour. Helminthol.* 9(1): 41-44. 1931.—*Helicella itala* and *Cochlicella acuta* (land snails) were fed with the eggs and developed young stages of a fluke. In the feces of 2 sheep fed with the latter species were found eggs of the fluke.—*F. J. Meggitt.*

16573. **CAWSTON, F. G. Les Schistosomes rares de l'Afrique du Sud.** *Ann. Parasitol. Humaine et Comp.* 8(3/4): 259-262. 2 fig. 1930.—The mollusks studied and the cercaria found were as follows: *Burnupia trapezoidea* Bttg. (Faust), cercaria of a monostome; *Limnaea natalensis* Kraus and *Segmentina planodiscus* (M. and P.), *Cercaria milleri; Segmentina planodiscus* (M. and P.), *Cercaria syncytadena; Physopsis africana, Cercaria oculata, C. secobii,* and *C. octadena* (Faust); *Physopsis, Cercaria gigantosoma; Bullinus (Isidora) tropica* (Kraus), *Cercaria gladii* (Faust). The adult form of *Schistosoma haematobium* and *S. bovis* has been recovered from guinea pigs to which *Physopsis* were fed. The ova of *S. bovis* resemble those found occasionally in the urine of patients in this region. The eggs are elongate and fusiform and are not easily confused with those of *S. haematobium.* The author thinks there is little doubt that 4 distinct schistosomes parasitise man at Natal: *S. haematobium, S. mansoni, S. bovis,* and *S. spindalis.* The distribution of the latter forms is discussed.—*H. E. Essex.*

16574. **CAWSTON, FREDERICK G. A consideration of the cause and cure of bilharzia disease.** *Urol. and Cutan. Rev.* 33(12): 817-820. 4 fig. 1929.—In 1916 and 1917 the author observed the accumulation of *Planorbis pfeifferi* Krauss and *Physopsis africana* Krauss in the Durban suburbs and recognized this as a possible risk, should *Schistosoma mansoni* be imported from Egypt. At the same time a schistosome (*Cercaria* gladii (p. 817)) was found infesting *Bullinus tropica* (Krauss) in the Transvaal. Examples of the adult *Schistosoma bovis* were reared at Durban from *Cercaria octadera* infesting *P. africana.* The same schistosome, along with another unidentified one, was obtained from Pinetown, Natal. Schistosomiasis is now recognized as responsible for dysenteric symptoms and sometimes death among sheep and cattle in the Cape Province and in the Transvaal. *Schistosoma bovis* is an occasional parasite of human beings in Natal. The paper includes photographs of wax models of various cercariae, a good variety of the shell of *P. africana,* models of the typical teeth of various spp. of freshwater mollusks, and camera lucida sketches of the ova of *Schistosoma bovis.*—*F. G. Cawston.*

16576. **CHODUKIN, N. J., M. S. SOFIEFF, F. J. SCHEVTSCHENKO, und G. L. RADSIVILOVSKIJ. Phlebotomus als Überträger von Hunde-Leishmaniose.** *Arch. Schiffs- u. Tropen-Hyg.* 35(7): 424-434. 1931.—A 3-yr. experimental study in central Asia indicates that *Phlebotomus papatasii, P. sergenti, P. chinensis, P. major* and *P. caucascicus* are all potential vectors of canine leishmaniasis.—*E. C. Faust.*

16577. **DEVILLE, C., J. DUVAL, R. VINZENT, et F. DÉVÉ. Un cas d'échinococcose alvéolaire originaire du Wurtemberg observé en Normandie.** *Compt. Rend. Soc. Biol.* 106(12): 1120-1122. 1 fig. 1931.—A case of alveolar echinococcus in a man of 27 who had left Württemberg at the age of 20 is described, histologically (from a biopsy) and biologically (deviation of complement, etc.). The intradermal reaction to various hydatid antigens was about the same, showing the errors likely to occur in using this method to determine the species of echinococcus present. This disease is unknown in Normandy, where the patient had lived most of the time after leaving Württemberg.—*E. Weiner.*

16578. **EUSTATZIU, G., et V. IONESCO. Contribution à l'étude de la pathogénie de l'accès de malaria et conclusions qu'on en peut tirer pour la malariothérapie.** *Arch. Roumaines Path. Exp. et Microbiol.* 2(2/3): 325-338. 1929.—In Rumania only 56% of peasants were successfully inoculated with malaria in the treatment of general paralysis, due probably to a partial immunity established by previous naturally acquired malaria infections. The authors discovered that by increasing the dose of blood containing quartan parasites intravenously injected from the usual 5 or 10 cc. to 200-350 cc. this resistance was overcome and typical quartan accesses followed in 100% of the cases. At the same time the quartan malaria remained equally benign and susceptible to quinine therapy.—*L. W. Hackett.*

16579. **GARNHAM, P. C. C. Malaria in Kisumu, Kenya Colony.** *Jour. Trop. Med. & Hyg.* 32(15): 207-216; (16): 221-231. 12 fig. 1929.—A study of malaria in a town of 7000 inhabitants on Victoria Nyanza, is reported. *Anopheles funestus, A. pretoriensis, A. squamosus, A.*

maculipalpis, A. gambiae (*costalis*), *A. pharoensis* and *A. mauritianus* (the last 3 also found by previous observers), were discovered; also *A.* symesi and a species resembling but not identical with *A. transvaalensis*, the larvae of both being described and the breeding places of all the above discussed. There are 2 distinct types of *A. funestus* larvae; the atypical one has small abdominal plates and other points of difference. Regular adult counts for 2 years showed a high *A. funestus* level throughout and a marked seasonal production of *A. gambiae*. The peaks of the former showed no relation to the rainfall, whilst *A. gambiae* appears *pari passu* with the "long rains" and at no other time, not even after other rainy periods. Variations in density of *A. funestus* adults is in direct proportion to the proximity of its breeding grounds. Very low oocyst and sporozoite rates of domestic *A. gambiae* and *funestus* (1386 dissections; less than 1% infected), and abnormalities of salivary glands, e.g., 4 lobes are noted. Habits of *A. gambiae* and *funestus:* (1) never sheltered in vegetation; (2) early morning entry into houses; (3) infestation of houses influenced by fire and presence or absence of occupants (the last factor also reverses the proportion of sexes, males showing an actual increase on vacation of a hut); (4) proximity to breeding-grounds has a less marked effect on the distribution of sexes; (5) direct and indirect methods of studying dispersal show that a slight daily accumulation (i.e., not complete redistribution) occurs. There is a high level of cases throughout the year, minimum of 200 per month. Seasonal rises follow the long rains only and therefore depend on the sudden appearance of *A. gambiae*. Endemic malaria is probably transmitted by *A. funestus;* the density of the latter does not appear to influence the amount of malaria (above a certain minimum). There is the unusual feature of a low spleen rate and a very high parasite rate for all ages and for all classes of population (non-hospital). Parasite rate shows a rapid increase in regard to age incidence up to the maximum of nearly 100% at the period ½-3 years, then a gradual diminution until the minimum of ⅓-½ infected is reached in the adult population. Seasonal variations (slight) in the parasite rate are probably due to the appearance and disappearance of *A. gambiae*. Local variations are due not to anopheles density but to the habits of the people concerned. Species of parasite is nearly always *Plasmodium falciparum*, with an increase of *P. malariae* after the anopheline season, possibly due to its large gamete output. Extremely low crescent rate (usually less than 1%) occurs at all seasons, at all hours of the day and after repeated examinations. The other two species (rare) show very high gametocyte rates (up to 68% of their respective infections). It is difficult to reconcile the high parasite rate and the low gamete rate. Crescent production may be increased after epidemic malaria, but there is some evidence against this. Age does not affect crescent incidence. Very bad ventilation may be a predisposing cause.—*P. C. C. Garnham.*

16580. [GLADINA, S.] ГЛАДИНА, С. Экспериментальное исследование над влиянием жука **Paederus fuscipes Curt. (cem. Staphylinidae)** на глаз кролика. **[Effect of P. fuscipes on the rabbit's eye.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 7(1): 18-22. [German summary, 136.] 1928.—Extract from living beetles was injected into the eyes of 7 rabbits. The skin of the lids, conjunctiva of lids and eyes, cornea, and iris were affected; irritation appeared in 2-5 hrs. and reached its maximum on the 4-5th day. In particular the author noticed considerable blepharitis, acute inflammation of conjunctiva with much muco-purulent discharge, diffuse cloudiness of the deep layers of the cornea, and, in 1 case, a purulent infiltration. Iris always participated in the inflammation.

16581. GOODEY, T. Further observations on Tylenchinema oscinellae Goodey, 1930, a nematode parasite of the frit-fly. *Jour. Helmithol.* 9(3): 157-174. 2 fig. 1931. —Adults were found in the body-cavity and larvae throughout the whole of the gut; the point of entry into the gut was the food reservoir. Occasionally, more especially in the panicle generation, the host obtains the ascendency. Free-living larvae undergo third ecdysis after 17 hrs. and the final after 41. Copulation within a confined space is necessary for fertilization; the ♀ is not a protandrous hermaphrodite. The percentage of infection is 4.3 in the overwintering generation, 9-14 in the stem generation, and 2.89-5.3 in the panicle generation. ♂♂ are more highly infected than ♀♀. Usually only one worm per fly was found. Infected frit-flies were obtained from Lyngby (Denmark), Kiel (Germany), Leningrad (Russia), France, Washington (D. C.). A comparison with *Howardula benigna* Cobb 1921 is given. —*F. J. Meggitt.*

16582. GOOR, J. M. NOOTHOVEN van. Bijdrage tot het vraagstuk der beteekenis van lamblia intestinalis voor de menschelijke pathologie. [Pathogenic influence of L. intestinalis in man.] *Nederlandsch Tijdschr. Geneesk.* 73(48): 5557-5568. 1 pl. 1929.—The author concludes that it is not proved that *L. intestinalis* is a pathogenic flagellate for the duodenum; vegetative forms of *Lamblia* may be found in the content of the upper part of the ileum, even when cysts are not found in the feces; it is not proved and even very improbable that Lamblias may produce inflammations of the gall-bladder or the larger gall-ducts.—*J. W. Langelaan.*

16583. GRIGOROWA, O., und M. NESTURCH. Filariose bei jungen Schimpansen. *Zeitschr. Wiss. Biol. Abt. F, Zeitschr. Parasitenk.* 2(5): 616-628. 2 fig. 1930.—A record of filariasis in a young chimpanzee, due to *Microfilaria perstans**, with results of blood examinations.

16584. HEGNER, ROBERT. The infection of parasite-free chicks with intestinal Protozoa from birds and other animals. *Amer. Jour. Hyg.* 10(1): 33-62. 3 fig. 1929.—Caecal material from guinea-pig, rat, guinea-fowl, duck, owl, quail, etc., infected with spp. of *Chilomastix, Endamoeba, Trichomonas, Balantidium, Endolimax*, and *Coccidium*, and *Trichomonas buccalis* from the human mouth, were inoculated per os or per rectum into young chicks of various ages. In general the chicks were very susceptible to the "foreign" protozoa, some remaining infected for long periods, some passing viable specimens of infective stages, in many the foreign protozoa reacting markedly to the changed environment, while in a few negative results only were obtained. *Endolimax* **numidae*** (p. 45) from guinea-fowl, *Trichomonas* **anseri*** (p. 48) from a goose, *Tritrichomonas* **floridanae*** (p. 52) and *Trichomonas* **ortyxis*** (p. 52) from quail are described; many new unnamed parasites were found. The advantages of parasite-free chicks as laboratory animals for the study of host-parasitic relations of intestinal protozoa are emphasized.—*M. W. Kamm.*

16585. HEGNER, ROBERT, and H. J. CHU. A survey of protozoa parasitic in plants and animals of the Philippine Islands. *Philippine Jour. Sci.* 43(3): 451-482. 5 pl. 1930.—Practically no studies had previously been made of the protozoa that live in the animals and plants of the Philippine Islands. This paper is intended as a preliminary survey and guide for further work. Animals were collected at random, and their protozoan parasites listed. The mammals examined included monkeys, carabao, pigs (wild and domesticated), dogs, rabbits, guinea-pigs, rats, civet cats, bats and flying lemurs. Protozoa are also recorded from many species of domesticated and wild birds, from reptiles, amphibia, insects and snails. Flagellates were found in only one of many species of latex-bearing plants examined. About 60% of plants of *Euphobia hirta* were infected.—*R. Hegner.*

16586. HOBMAIER, A., und M. HOBMAIER. Über das Verhalten der Lungenwürmer des Schweines, Metastrongylus longevaginatus und Choerostrongylus brevivaginatus, sowie von Dictyocaulus filaria des Schafes im Pferde, mit Bemerkungen zur pathologischen Anatomie des Haemomelasma ilei et jejuni des Pferdes. *Münchener Tierärzt. Wochenschr.* 81(29): 361-364. 2 fig. 1930.—Feeding larvae of *Metastrongylus longevaginatus*

(*M. elongatus*) and *Choerostrongylus brevivaginatus* (lungworms of swine), or of *Dictyocaulus filaria* (of sheep) to the horse is not likely to result in development of adult worms; neither nematode nodules in the lungs nor hemomelasma of ilium and jejunum are produced. The observed eosinophilia and hemosiderosis of the mesenteric lymph nodes cannot definitely be attributed to an invasion of lungworm larvae. In hemomelasma of the horse, serial sections showed nematode nodules in the submucosa, mucosa, muscularis and rarely in the subserosa; these are implicated in the alteration (hemomelasma) of the subserosa. Hemomelasma therefore appears to be primarily an alteration of the submucosa (follicle mucosa, muscularis) beneath the intestinal lymph follicles, and secondarily an alteration of the subserosa.—*Authors' summary (transl. by O. L. Williams).*

16587. HOBMAIER, ADELE, und MICHAEL HOBMAIER. Biologie von Choerostrongylus [Metastrongylus] pudendotectus [brevivaginatus] aus der Lunge des Schweines, zugleich eine vorläufige Mitteilung über die Entwicklung der Gruppe Synthetocaulus unserer Haustiere. [Biology of C. pudendotectus in the pig's lung, and preliminary note on development of the Synthetocaulus group in domestic animals.] *Münchener Tierärztl. Wochenschr.* 80 (31) : 433-436. 3 fig. 1929.

16588. HOLT, R. L., and P. F. RUSSELL. Spleen survey of the eastern shore of Bataan Province, Luzon. *Philippine Jour. Sci.* 45 (2) : 211-219. Map. 1931.—Prevalence of malaria is gauged from a correlation of spleen findings and mosquito survey. Malaria is rare on the eastern coast of Bataan except as imported from the foothills nearby. *Anopheles ludlowii* was commonly encountered in the salt water marshes of this region but is not an effective vector of malaria in this locality. Ten species of Anophelines were found. Nearness of the town to the foothills increases the malarial rate. *Anopheles minimus* was found in the streams in the foothills.—*R. L. Holt.*

16589. ISHII, N., and TEI TOK WA. Studies on the frequency of parasites and their connection with vegetables in Amoy, China. *Taiwan Igakki Zasshi (Jour. Med. Assoc. Formosa)* 30 (8) (No. 317, Aug.) : 61-62. 1931.—Fecal examination of 634 persons in Amoy showed a parasite infection rate of 66.72%. Amoebae were most common in adult ♂♂ and *Ascaris* in young ♂♂. This rate is intermediate between Tokyo (54.26%) and Canton (77.09%). 17 kinds of vegetables examined showed eggs of *Ascaris lumbricoides, Oxyuris vermicularis, Ancylostoma duodenale, Trichocephalus* and *Taenia saginata,* and cysts of *Balantidium coli.*—*E. C. Faust.*

16590. JANICKI, CONSTANTIN, und KAREL RAŠÍN. Bemerkungen über Cystoopsis acipenseri des Wolga-Sterlets, sowie über die Entwicklung dieses Nematoden im Zwischenwirt. *Zeitschr. Wiss. Zool.* 136 (1) : 1-37. 26 fig. 1930.—A careful morphological description is given of both ♂ and ♀ nematodes found encysted immediately beneath the skin on the ventral surface of the host, *Acipenser ruthenus.* The mature ♀ apparently does not deposit eggs but bursts. Experimental infection of *Dikerogammarus haemobaphes* and *Gammarus platycheir* were successful. Eggs were taken in by the intermediate hosts per os and hatched after 4 hrs.; the larvae then bored through the wall of the alimentary tract and into the body cavity of the intermediate host. They remain in the body cavity for about 2 weeks and then penetrate the muscles of various appendages, such as the coxal joints, where they become spirally coiled and encysted.—*B. G. Chitwood.*

16591. JÍROVEC, OTTO. Fauna zažívacího traktu termita Calotermes lucifugus z Řecka. *Rozpravy České Akad. Věd. a Umění, Tř. 2* 39 (číslo 49) : 1-15. 1 pl., 18 fig. 1929 (1930). Also as: **La faune du tube digestif du Calotermes lucifugus récolté en Grèce.** *Acad. Tchèque Sci. Bull. Internat. Rés. Trav. Présentés Cl. Sci. Math., Nat. et Méd.* 30: 346-356. 1 pl., 18 fig. 1929.—Descriptive notes are given in Czech in the original paper (in *Rozpravy*) on the spp. found. These include, bacteria and spirochaetes: *Spirochaeta termitis*, S. minei*, S. hilli*, Fusiformis hilli*, F. termitis*, Paraspirillum* sp. (possibly a young stage of *F. termitis*). Flagellates: (Pyrsonymphidae) : *Pyrsonympha granulata*, P. major*, P. minor, Dinenympha gracilis*, D. fimbriata*;* (Hypermastigidae) *Holomastigotes elongatum** and *Spirotrichonympha flagellata*; Sphaerita** sp. in the *Dinenympha* and *Pyrsonympha* spp., cocci, and vibrios.

Orig. 7-12. 1930 (1931).—Trematoda: *Opisthioglyphe rastellus* in *Rana temporaria; Diplodiscus subclavacus* in *Rana esculenta;* a metacercarian of *Harmostoma* sp. in *Hyalinia cellaria;* metacercaria of *Echinostoma revolutum* in *Limnaea vulgaris,* the cercaria are described, encystment taking place in *Herpobdella octoculata; Cercaria virgula* in *Bithynia tentaculata.* Cestoda: *Archigetes sieboldii* in *Tubifex tubifex; Bothriocephalus scorpii* in *Cottus bubalis; Raillietina (Skrjabinia) cesticillus* and *Choanotaenia infundibulum* in domestic fowl; *Hymenolepis collaris, H. coronula, H. gracilis,* and *Fimbriaria fasciolaris* in duck; the *H. gracilis* cysticercoids were found in *Cyclops* and *Cypris,* and in *Limnaea vulgaris* and *L. pulustris* which had eaten infected *Cypris; Cysticercus pisiformis* in wild rabbit; cysts of *Cladotaenia cylindracea* in the liver of *Microtus arvalis; Multiceps serialis* in domestic rabbit. Nematoda: *Ascaridia gralli* in intestines of chicken and turkey; *Porrocaecum crassum* in the duck; *Passalurus ambiguus* and *Trichostrongylus retortaeformis* in wild rabbit. Acanthocephala: *Polymorphus minutus* in the duck.

16593. KHALIL, M. B. The specific treatment of human schistosomiasis (bilharziasis), with special reference to its application on a large scale. With notes: (1) Über fuadin (neo-antimosan), by HANS SCHMIDT; (2) The physiological action of the antimosan compounds, by M. M. HAMMOUDA; (3) Über die Beeinflussung des Blutkreislaufes durch einige Antimonpräparate, by H. WEESE. *Beih. Arch. Schiffs- u. Tropen-Hyg.* 35 (2) : 1-128. 1931.—This monograph is essentially a clinical paper but has a certain biological value, since it deals with an infection caused by the human blood flukes, *Schistosoma haematobium* and *S. mansoni,* and also incorporates a considerable amount of experimental evidence on the toxicity of antimony compounds. Exhaustive bibliographies accompany each section.—*E. C. Faust.*

16594. KHAW, O. K., und R. HOEPPLI. Ekto- und Endoparasiten chinesischer Bettler in Peiping. *Arch. Schiffs- u. Tropen-Hyg.* 35 (8) : 443-448. 1931.—Based on a survey of 100 beggars in Peiping, ranging in age from 2 to 80 years, the authors identified lice, *Sarcoptes scabiei* and *Pulex irritans,* as well as the common intestinal protozoa and helminths of the area. The protozoan index (180%) is the highest recorded for north China. Only 3 of the group were free from endoparasites and 23 of ectoparasites. The data indicate the exceedingly unhygienic condition in which these beggars live.—*E. C. Faust.*

16595. [KOMENDATOV, V.] КОМЕНДАТОВ, В. К эпидемиологии малярии на Северном Кавказе. (On the epidemiology of malaria in the Northern Caucasus.) Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol., et Parasitol.*) 9 (1) : 90-95. [English summary p. 134.] 1930.—The author calls attention to the several peculiarities in the epidemiology of malaria in the Northern Caucasus. While the epidemic was tropical in character the investigation of the blood of the population conducted for a year revealed 70% of tertian parasites. The substitution of the tropical parasite for the tertian in the blood of the population occurred in every locality, and was followed by mass recovery; the possibility of mixed infection was doubtful. Investigation of 30,000 pupils showed that the tropical parasite was most frequently found among

children 11-14 years old, especially among the poorer classes.—*G. A. Lebedeff.*

16596. **LADA, LAKSHMANA SADASHIVA. Um caso de amebiase pulmonar. [Case of pulmonary amebiasis.]** *Arq. Escola Méd.-Cirurg. Nova Goa Ser. B* Fasc. 3. 510-512. 1930.

16597. **[LEVIN, I. I.]** ЛЕВИН, И. И. К методике диагностики энтеробиоза. [Diagnosis of enterobiasis.] [German summary.] Одеський Медичный Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 155-174. 1930.—Fülleborn and Telemann's smear methods are inadequate for detecting *Enterobius vermicularis* or its eggs. Diagnostic dehelminthization is too complicated, expensive, and time consuming. The most adequate methods are perianal grattage and microscopic examination of subungual material. The latter gave positive results in 87.8% of enterobiasis cases.—*B. Van Rosen.*

16598. **ŁUKASIAK, JAKÓB. Anatomische und entwicklungsgeschichtliche Untersuchungen an Dioctophyme renale (Goeze 1782) [=Eustrongylus gigas Rud.]** *Arch. Biol. Towarzystwa Naukowego (Arch. Biol. Soc. Sci. et Lettr. Varsovie)* 3(3): 3-100. 6 pl. (partly col.), 6 fig. 1929(1930).—*D. renale* is rather frequent in the dog in Warsaw and its environs; out of 2338 dogs inspected there were 88 infected. The parasite in dogs was found in the right kidney (69.3%), liver (16.6%) and other parts of the abdominal cavity (14.1%), never in the left kidney. In 20 cases both ♂ and ♀ worms were found. The parasitized kidney is completely destroyed, only a thin pellicle remaining. Anatomic details concerning the nervous, excretory, muscular, digestive, and reproductive systems are given in detail. In 82 ♀♀ and 62 ♂♂ dissected, only 4 young specimens were found; very young specimens were never found. The embryonic development of the fertilized egg in water lasts 1-7 months, according to the temp. A fully-developed embryo attains the length of 0.279 mm.; probably the embryo does not get rid of the egg-cover by its own efforts. It keeps its vitality up to 2 years. After being set free mechanically from its egg-cover it is able to live in water for 2 hours. *J. Łukasiak.*

16599. **LYNCH, KENNETH M. Protozoan parasitism of the alimentary tract. Pathology, diagnosis and treatment.** 258p. 37 fig. Macmillan Co.: New York, 1930. Pr. $3.75.—Written from the viewpoint of the medical man, the book attempts to put the scattered facts on pathogenesis, diagnosis and treatment of intestinal protozoiasis in a form immediately available to the medical profession and laboratory technician. The biology of the parasitic protozoa, including life-history, morphology, immunity, prophylaxis, etc., is briefly discussed. The accepted and some doubtful species of amoebae, flagellates, ciliates and coccidia infesting the human mouth, intestine and vagina are considered in the order named, as well as the technique peculiar to their observation. The ubiquitous *Blastocystis hominis* is also considered.—*R. M. Stabler.*

16600. **McCOY, O. R. The egg production of two physiological strains of the dog hookworm, Ancylostoma caninum.** *Amer. Jour. Hyg.* 14(1): 194-202. 1931.—The egg production of a cat strain in cats was approximately 2,350 eggs per day per ♀ as compared with the normal egg production of 16,000 eggs per day per ♀ by a dog strain in dogs. The dog strain when introduced into cats produced an average of only 2,340 eggs per day, approximately the same number as did the cat strain. Infections of the dog strain in the cat, however, were of shorter duration than those of the cat strain. When infections of the cat strain were established in dogs, the egg production averaged 11,600 eggs per day per ♀. Apparently egg production is controlled by the host and is not inherent in the strain of worms.

16601. **MANWELL, REGINALD D., and CARL MILTON JOHNSON. A natural trypanosome of the canary.** *Amer. Jour. Hyg.* 14(1): 231-234. 1931.—In canaries 16 cases of natural and 1 of artificial trypanosome infection were observed. The mite *Dermanyssus gallinae* is probably the vector. The trypanosome resembles both *Trypanosoma paddae* and *T. gallinarum* in shape, but differs from both in size; it is believed to be a variety of the latter, not hitherto reported from the Western Hemisphere.

16602. **MAROTEL. La lutte antidistomienne. (3me note.)** *Rev. Vét. et Jour. Méd. Vét. et Zootech.* 83 (Aug.): 417-424. 1931.—Terebenthine-benzol has been found an excellent treatment for trematode infestations.

16603. **MELLO, F., de. Infusoires parasites de Racophorus maculatus Gray.** *Compt. Rend. Soc. Biol.* 106 (12): 1184-1185. 1931.—The following infusorians were found in the intestine of *R. maculatus* in the region of Nova Goa: *Nyctotherus papillatus* Dobell; *Opalina virgula* Dobell; *O. (Cepedea) longa* Bezzenberger; and *O. (Cepedea)* thiagi (p. 1184).—*E. Weiner.*

16604. **MAZZA, SALVADOR, y E. RICKARD. Relación del cultivo de arroz con la difusión del paludismo en la provincia de Tucumán. (Informe sobre estudios en una estación completa.) [Relation of the cultivation of rice to dissemination of malaria in Tucuman.]** *Quinta Reuniòn Soc. Argentina Patol. Reg. Norte* 2: 707-711. 1930.—The spp. of Anopheline larvae found in the rice fields belong to the group *Nyssorhynchus*, principally *Anopheles albitarsis* and *A. tarsimaculatus*. There is no proof that these spp. have any importance in the transmission of malaria in the north of Argentina. *A. pseudopunctipennis*, principal transmitter of malaria, is found especially around the rice fields and not in the rice fields themselves. The destruction of the larvae near rice fields seems advisable. It is believed that suppression of rice cultivated would increase rather than diminish the dissemination of malaria.—*D. de Rivas.*

16605. **MESA, ERNESTO OSORNO. Caso de perforación del velo del paladar por larvas de Chrysomyia macellaria Fabricius. [Perforation of the soft palate by larvae of C. macellaria.]** *Bol. Soc. Colombiana Cien. Nat.* 16(93): 157-161. 1 pl. 1927.—This records a case in a man 50 yrs. of age.

16606. **MESNARD, J., et H. MORIN. Réceptivité naturelle de l'Anopheles (Myzomyia) aconitus à l'infection par l'hématozoaire du paludisme en Cochinchine.** *Bull. Soc. Path. Exotique* 24(7): 554-556. 1931.—Of 13 spp. of Cochin-China mosquitoes examined, only *A. aconitus* and *A. minimus* were infected with malarial parasites.

16607. **MIESSNER, HERMANN. Piroplasmosen und Splenektomie.** *Arch. Wiss. u. Prakt. Tierheilk.* 63(1): 78-90. 6 fig. 1931.—Dogs injected with *Babesia canis* have a mild transitory infection with only a few parasites in the blood. A dog with generalized carcinomatosis died of a severe infection with *Babesia canis* a few days after inoculation. The carcinomatosis appeared to have blocked the reticulo-endothelium. Relapses, which are more severe than the first illness, occurred in splenectomized dogs infected with *Babesia canis;* complete recovery occurs, however. Infections with *Babesia bovis* and *Babesia bigemina* do not result in cross immunity. The experiments of Smith and Kilborne (1893) on the transmission of Texas fever through the larvae of *Boophilus bovis* were repeated. Splenectomy of cattle infected with *Babesia bovis* and *Babesia bigemina* brings about severe and fatal relapses. The blood showed thrombocytosis, monocytosis, polychromy, anisocytosis, and the presence of Jolly bodies. The spleen is of great importance in protecting dogs and cattle against *Babesia.* In an infected cow, subsequently splenectomized, small rod-like, round, and dumb-bell shaped bodies appeared in the red blood cells; these were considered to be *Theileria mutans.* Trypan blue has a more favorable parasiticidal action against babesiosis than trypaflavine and ichthargan. A cow which for some years had excreted almost a pure culture of *Paratyphosus B* (Schottmüller), showed, some days after splenectomy, only *B. coli* in its faeces. Beginning on the fourth day, however, the Paratyphoid bacilli appeared in the blood, apparently from the again active gall bladder, and completely displaced the *B. coli.*—*Author's summary (transl. by R. W. Linton).*

16608. **MILAM, DANIEL FRANKLIN, and HENRY E. MELENEY. Investigations of Endamoeba histolytica and other intestinal protozoa in Tennessee. II. An epidemiological study of amoebiasis in a rural community.** *Amer. Jour. Hyg.* 15(2): 325-336. 1931.—In a community comprising 75 families and 374 individuals, 38% of the population harbored *E. histolytica* cysts, and clinical dysentery had occurred in about ¼ the population; but the attacks clinically simulated bacillary rather than amebic dysentery and no correlation was found between the occurrence of dysentery and the harboring of *E. histolytica*.

16609. **MORGAN, D. O. On the occurrence of Hepaticola hepaticola as a natural infection of the wild rabbit in England.** *Jour. Helminthol.* 9(1): 39-40. 1931.—Eggs and females were found but no males.—*F. J. Meggitt.*

16610. **MORGAN, D. O. On the occurrence of gapeworms in nestling starlings and adult fowls.** *Jour. Helminthol.* 9(3): 117-120. 1931.—*Syngamus trachea, Hymenolepis* sp., *Capillaria ovopunctata,* and *Porrocaecum ensicaudatum* (?) found in starlings which had never left the nest.—*F. J. Meggitt.*

16611. **MORGAN, D. O. Some observations on experimental ascariasis in pigs.** *Jour. Helminthol.* 9(3): 121-128. 1931.—One pig failed to become infected with embryonated eggs of *Parascaris equorum* but 6 pigs were infected with eggs of *Ascaris lumbricoides,* one dying within 60 hours. The infection of the others lasted 18-22 weeks. The results showed an absence of age resistance and acquired immunity.—*F. J. Meggitt.*

16612. **MORISHITA, KAORU, HIROSHI NAMIKAWA, TAMOTSU MATSUURA, and KUNISHIZU TANIKAWA. Report on the malaria epidemic in Uzanto and its control, with special reference to the effect of all quininization.** *Taiwan Igakki Zasshi* (*Jour. Med. Assoc. Formosa*) 30(7) (No. 316, July): 53-54. 1931.—Uzanto is a village in the midst of an irrigation project of 360,000 acres in Tainan Province, Formosa, initiated in 1920. A parasite rate of 8.3% malaria (spleen rate 21.1%) was determined in 1927. Mass quininization for 60 days in the spring of 1927 lowered the parasite rate to 2.3%.—*E. C. Faust.*

16613. **MOWRY, HELEN A., with ELERY R. BECKER. Experiments on the biology of infusoria inhabiting the rumen of goats.** *Iowa State Coll. Jour. Sci.* 5(1): 35-60. 1930.—The results showed that numbers of infusoria in the rumen depend upon the amount and kind of food consumed by the host. An increase and change in appetite, resulting in the consumption of more and richer feeds, led to an increase in number of rumen infusoria. The percentage of sediment in a sample of rumen contents was no indicator of the amount of protozoan fauna. The fauna was influenced to some extent, but not materially, by the pH of the rumen contents. The infusoria numbers showed no correlation with the weights of the goats. The results indicated that the relationship between the goat and the protozoan fauna in the rumen is one of commensalism. The protozoa present in the 3 goats studied varied somewhat, and included *Diplodinium multivesiculatum, D. ecaudatum, D. bursa, D. hamatum; Entodinium simplex, E. minimum, E. caudatum, E. furca, E. bicarinatum,* and *E. simplex.*—*H. A. Mowry.*

16614. **NATTAN-LARRIER, L., et B. NOYER. Trypanosome du dromadaire et trypanosome du cheval au Maroc. III.** *Bull. Soc. Path. Exotique* 24(7): 569-584. 1931.—Comparison of the strain of *Trypanosoma marocanum* found in the horse with that infesting the dromedary justifies the designation of the latter as a distinct variety, *T. marocanum* var. **cameli** (p. 573); morphological differentiation is detailed. Repeated passages through guinea pig and rat modify both the horse and dromedary strains toward an intermediate type. Repeated passages through the mouse of either the horse or the dromedary trypanosome produces a somewhat distinctive type. In the placental plasmodium of infected pregnant ♀♀ occur rounded or slightly oval forms of *T. marocanum* resembling the leishmanian stage of the trypanosome, but believed by the authors to be degenerate forms. In 5 experiments the authors were unable to find the filtrable forms which Ugo Reitani claims to have discovered; nor were they able to produce infection through the digestive tract from ingestion of infected tissues, as announced by Faure. Attempts to cultivate the trypanosome on laboratory media were unsuccessful.

Belgique* 10(2): 86-102. 1930.—The opinion previously held that Europeans are refractory to infection with *O. volvulus* is shown by report of 5 cases in Europeans to be untenable. The infrequency of infection among Europeans is probably due to their comparatively thick clothing, which the short mandibles of *Simulium damnosum,* the insect host of the filaria, are unable to pierce. The authors find that the location of the filarial nodules has no relation to the puncture inflicted by the insect, proving the migration of the adult filariae before their inclusion in the subcutaneous fibroma. These are ordinarily painless, as in the natives. In most cases the occurrence of a small number of perceptible *O. volvulus* cysts produces no appreciable effect on the skin.

[Changes in the blood of guinea pigs after single and repeated invasions by Ascaris larvae.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 7(1): 69-92. [English summary, 141.] 1928.—Experiments were made on 10 guinea pigs; ripe *Ascaris* eggs were introduced per os; in 1 case the invasion was repeated thrice. Observations of the blood were begun 2 wks. prior to the experiments (length of experiments, 6-36 days). The authors observed regular and independent changes in red and white blood cells. The curve of erythrocytes steadily decreased, reaching minimum on 10-14th day; erythropenia attained 43% of the initial figure; Hb decreased 5-60%. The anemia was of the oligochromemia type with a lowered color index. From 4th to 6th day of invasion the leucocytosis gradually increased, attaining 25-30 thousand on the 7-10th day. Decrease of lymphocytes in number was accompanied by increase in neutrophils; both changes reach maximum on 8-10th day. Eosinophilia was constant, reaching its maximum on 10-14th day. No regular changes were seen in monocytes and basophiles; the leucocytes, especially eosinophiles, appeared as results of the toxic effect of the *Ascaris* larvae. In an extensive experiment, the loss of wt. attained 23-30% of the original. The normal condition of blood was regained on about 30-36th day, except for Hb. Examination of a singly infected guinea pig 30 days after the invasion showed a normal liver; in case of 3 repeated invasions, the liver contained incapsulated parasites 7 wks. after the first. Here the liver acted as a barrier, and thus only leucocytary reaction was present, with no changes in erythrocytes or Hb.

16625. **SPREHN, C. Über die Magen-Darmtrichostrongylose der Schafe und ihre Bekämpfung. [Trichostrongylosis of sheep and its control.]** [Preliminary paper.] *Deutsche Tierärztl. Wochenschr.* 39(39): 615-616. 1931.

16626. **STAFSETH, H. J. Studies in the pathology of avian coccidiosis.** *Jour. Amer. Vet. Med. Assoc.* 31 (6): 792-816. 12 fig. 1931.—The disease in young chicks has its seat in the ceca and lower portion of the small intestine. In birds over 8 weeks old the ceca are very seldom visibly affected. Duodenal infection is most common and the other parts of the small intestines may be involved at times. The gross pathological changes in both cases are given. Some coccidia seem to do little damage, infecting only single cells here and there; others infect extensive areas of epithelium causing desquamation. Some infect glandular epithelium as well as villous epithelium causing desquamation of both. And again some cause "subepithelial" infection and produce sloughing of the mucous membranes. Apparently there are several spp. of coccidia, *Eimeria tenella* and *E. acervulina* having been recognized. Leg weakness and paralysis occur more frequently in connection with duodenal than cecal coccidiosis. Coccidia morphologically indistinguishable from some of those found in chickens were found in pigeons showing leg weakness. Coccidia were not found in the livers of infected chickens. No evidence was found to show that sparrows carry the Eimeria.—*From author's summary.*

16629. **STOCKMAYER, W. Erkrankungen und Todesfälle bei Affen infolge von Oesophagostomosis intestini.** *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39 (1/2): 70-76. 1 fig. 1931.—The author reports on typical cases. Animals showed catarrhal enteritis with nodule formation and perforation of the intestine and peritonitis in some. The lesions were mostly in the submucosa, where they gave rise to relatively slight reactions. Nine cases are reported in rhesus monkeys due to *Oesophagostomum apiostomum* (Willach). In 3 of these the parasite was found in the peritoneum where it had penetrated through the intestinal wall.—*L. D. Bushnell.*

16630. **STRADOMSKY, B. N., I. N. PETROWSKY, W. W. POPOW, und G. P. RUDNEW. Ist es möglich, die menschliche Malaria künstlich auf Versuchstiere zu übertragen?** *Arch. Schiffs- u. Tropen-Hyg.* 34(9): 515-521. 1930.—Human blood containing malarial organisms from human cases was injected into the following animals, almost all young and previously treated to lower their resistance to malarial infection: 2 guinea pigs, 15-17 days old, injected subcutaneously with a solution of benzol in oil for several days; 3 guinea pigs, 1-1½ mos. old, previously submitted to large doses of x-rays; 3 guinea pigs 3 mos. old and 2 dogs 2-4 months old, previously splenectomized; 1 guinea pig, 1½ mo. old, splenectomized 4 days after the injection of malarial blood; 2 dogs, 2-3 mos. old, previously injected with collargol to block the reticulo-endothelial system; 1 grown rabbit and 1 dog 4 mos. old in which both splenectomy and blockage of the reticulo-endothelial system had been done. In only a few cases and in these only during the 1st hr. after subcutaneous or intravenous injection of malarial blood could malarial parasites be found in the circulating blood and then in very small numbers. Subsequent examinations were entirely negative. These results do not confirm Joshino's claim that human malarial infection can be transmitted to experimental animals.—*E. C. L. Miller.*

16631. **TALICE, RODOLFO V. Sobre Helmintiasis por Hymenolepis en el Uruguay. [Human infestation by Hymenolepis in Uruguay.]** *Quinta Reunión Soc. Argentina Patol. Reg. Norte* 2: 1076-1081. 1930.—Report of 24 cases of human infestation by *Hymenolepis*, mainly by *H. nana*, in about 2200 examined persons.—*A. de Assis.*

16632. **TAYLOR, E. LEONARD. Some factors concerning the occurrence of disease due to strongyloid worms in grazing animals—verminous gastritis, hoose and equine strongylidosis.** *Vet. Rec.* 10(28): 602-606. 1 fig. 1930.—This is a general discussion of the methods of infection with these parasites, the importance of overstocking, close-grazing, nutrition and moisture in causing parasitic disease due to bursate nematodes.—*T. W. M. Cameron.*

16633. **VELU, H., L. BALOZET, et G. ZOTTNER. Infections mixtes trypano-spirochétiennes (Trypanosoma marocanum + Spirochaeta hispanicum).** *Compt. Rend. Soc. Biol.* 106(12): 1092-1094. 1931.—Two guinea pigs were inoculated with trypanosomes 64 and 69 days respectively after inoculation with spirochaetes. In one the spirochaetes did not reappear in the blood although the trypanosomes recurred 3 times before the animal died. The other animal required 3 inoculations with

trypanosomes before symptoms appeared. A few spirochaetes appeared in the blood 154 days after inoculation with spirochaetes and 49 days after inoculation with trypanosomes. This confirms the results of Delorme and Anderson with *T. brucei* and *S. duttoni*. In 7 cases of mixed infection, spirochaetosis had no effect on trypanosomiasis but the latter provoked the reappearance of spirochaetes long after inoculation and attenuated the crises by reducing their duration and frequency.—*E. Weiner.*

16634. **WILSON, IRL DONAKER A study of bovine coccidiosis.** *Virginia Agric. Exp. Sta. Tech. Bull.* 42. 1-44. 7 pl. 1931.—The most complete review of the literature yet published shows that bovine coccidiosis is widely spread, occurring in dry and moist climates and during warm and cold seasons. The author's observations indicate this protozoan is present in the intestinal tract of many apparently normal cattle in widely separated sections of America, but becomes numerous enough to produce serious disturbances only occasionally. In some areas the disease causes serious annual losses in calves. *Eimeria zurnii* is the species most common, although *E. smithi* and *E.* cylindrica* (p. 12) are usually present. A review of the literature shows that what little research has been done with this disease has for the most part been fragmentary, and many contradictory statements have been made. The author finds the oocysts of the spp. of *Eimeria* affecting cattle highly host-specific, that they are killed by 10 min. exposure at 55° C., by prolonged freezing, direct sunlight, prolonged drying, putrefaction, 0.3% $HgCl_2$, 5% phenol, 4% formalin, and 2% liquor cresolis comp. They may be successfully incubated in 2% $CuSO_4$, or 2% $K_2Cr_2O_7$, and are not injured by centrifuging. The author was unsuccessful in digesting the oocyst wall in vitro or in young rats. The prepatent period is about 7 days followed by a period of about 30 days when the oocysts are eliminated in great numbers, ending in the animal becoming immune or resistant, or it may become a chronic carrier if death does not occur. The author believes that recovery from the disease may be due to immunity rather than to a limited number of asexual generations as has been suggested for some species. The symptoms are bloody diarrhea, followed by emaciation and weakness; the appetite remains fair and there is no rise of temperature. Autopsy findings are principally enteritis, ranging from catarrhal to hemorrhagic, and, in severe cases, sloughing of the intestinal epithelium. The pathologic changes and morphology of the four species of *Eimeria* affecting cattle are illustrated by photomicrographs. A list of 115 references is appended.—*I. D. Wilson.*

16635. **YAKIMOFF, W. L. Endoglobuläre Parasiten der Schafe im Nordkaukasus. [Endoglobular parasites of sheep in the North Caucasus.]** *Arch. Protistenk.* 65 (1/2) : 151-164. 1 pl., 43 fig. 1929.—Smears from the peripheral circulation and spleen were studied. The author concludes that 4 distinct parasites can be recognized: *Piroplasma ovis, Babesiella ovis, Gonderia ovis,* and *Theileria ovis.* These are the first observations on piroplasmosis recorded from the North Caucasus. Extensive bibliography.—*M. E. Larson.*

16636. **YAKIMOFF, W. L., et W. P. BASKAKOFF. A propos de la coccidiose du mouton en Russie (U.R.S.S.).** *Arch. Ital. Sci. Med. Coloniali* 11 (9) : 517-521. 1930.—Description of an epizootic disease of sheep, caused by trichostrongylids and by coccidia. *Eimeria ninae kohl-yakimov* Yakimoff and Rastegaieff, 1930 (average dimensions of oocysts 25.1$\mu \times$ 18.7μ, of sporocysts 8.3$\mu \times$ 5.9μ), and *Eimeria intricata* Spiegl, 1925 (average dimensions of oocysts 47.8$\mu \times$ 8.5μ). Treatment with CCl_4 did not influence the disease.—*W. L. Yakimoff (transl. by H. Kirby).*

16637. **YAKIMOFF, W. L., et E. F. RASTEGAÏEFF. L'essai de l'infection des bovidés avec le Françaiella colchica par les tiques.** *Zentralbl. Bakt. I. Abt. Orig.* 112 (1/2) : 69-73. 1929.—In North Caucasia the auth gathered from infected animals ticks which were c tivated in the laboratory. Using the resulting larvae *Boophilus annulatus calcaratus* Bir., a healthy milk-c was infected with *Françaiella colchica.* On the 11th d the temp. rose, and 5 days later the parasites were fou in the peripheral blood. Next day there was haemog binuria. The incubation period is 11 days. Death curred on the 18th day. Therefore, *B. a. calcaratus* the vector of *F. colchica* in North Caucasia. Tab show the form of the parasites, minute details of t blood condition, the infected organs, and the progr of the disease. Comparing this infection to piroplasm sis caused by *Françaiella* (*Babesiella*) *major* in Alge it is seen that the latter is not fatal, whereas the C casian form is. No spleen rupture was observed in No Caucasia. The Algerian authors (Ed. Sergent and c laborators) think that *F.* (*B.*) *major* is responsi for spleen rupture in Europe.—*C. I. Mactaggart.*

16638. **[ZHADIN, V. I.] ЖАДИН, В. И. FILTERABLE VIRUSES, BACTERIOPHAGE, ETC.

GEO. H. SMITH, *Editor*

(See also in this issue the subsection "Infectious Chloroses" in the section Phytopathology; and Entries 15658, 16304, 16533, 16549, 16550, 16551, 16674, 16678, 16694, 16695, 16704, 16722)

GENERAL

16644. **AUBERTIN, E., et V. REYNES. Sur la mise en évidence, par inoculation dans les ganglions lymphatiques du cobaye, de virus filtrant tuberculeux provenant de crachats bacillifères.** *Compt. Rend. Soc. Biol.* 106 (12): 1161-1163. 1931.—Sputa containing tubercle bacilli were incubated for 3-4 hrs. and then filtered through a Chamberland filter L3. Sterility of the filtrate was shown by culture in different media and by examination after Gram and Ziehl-Nielsen staining. The filtrates were inoculated into the carotid ganglia or subcutaneously at the base of the neck in guinea pigs. The glands were removed after different periods, and, after being emulsified in physiological saline, were inoculated into the carotid ganglia of other guinea pigs and examined by the Ziehl-Nielsen method. Following intraglandular injection, acid-fast bacilli are evident after about 12 days, instead of after the month required with subcutaneous injection; but results are inconstant. Of 13 cases, only twice were typical bacteria seen after the 1st inoculation; the 2nd gave 5 positives in 9 cases. In the succeeding inoculations, the number of positives became smaller (3 in 18 cases).—*E. Weiner.*

16645. **AUBERTIN, E., et V. REYNES. Lésions tuberculeuses produites par le virus filtrant provenant de crachats bacillifères et transmis de ganglion à ganglion chez le cobaye. L'ultravirus tuberculeux recupère-t-il un pouvoir pathogène analogue à celui du bacille de Koch ordinaire?** *Compt. Rend. Soc. Biol.* 106 (12): 1163-1166. 1931.—5 guinea pigs received injection of filtered tuberculous sputum in the glands of the neck. 6 succeeding lots were inoculated, one from the other, with emulsions of these glands. After removal of the glands the animals were autopsied. In general, in the 18 examined, acid-fast bacilli were found in the glands 200-250 days after inoculation. A few, tested with tuberculin, gave negative results. The ultravirus produced, in a few cases, lesions in the liver, spleen and other organs, which appeared typical, although bacilli could not be found on direct examination. Inoculation of an emulsion of these organs into 3 guinea pigs produced lesions in 1 animal, none showing bacilli. Inoculation of fragments of organs from the animal with lesions, into 2 guinea pigs produced a typical lesion at point of inoculation in one, adenopathy of the surrounding glands, and hypertrophy of the mesenteric and tracheobronchial glands. Bacilli were present in the glands of the neck. The lesions produced by the ultravirus differ from those produced by Koch's bacillus, the lesion at the point of inoculation often being absent; and the lesions produced by the ultravirus are not transmissible in series, although the same strain was used throughout. The health of the animal is important in production of lesions.—*E. Weiner.*

16646. **BADGER, L. F., R. E. DYER, and A. RUMREICH. An infection of the Rocky Mountain spotted fever type. Identification in the eastern part of the United States.** *U. S. Publ. Health Repts.* 46(9): 463-470. 1931.—A virus was isolated from cases of a disease, occurring in the eastern part of the U. S. A., which clinically resembles typhus fever or Rocky Mountain spotted fever. The virus, studied in guinea pigs, monkeys and rabbits in comparison with the viruses of Rocky Mountain spotted fever, endemic typhus and epidemic typhus, is regarded as the etiological agent of an eastern type of Rocky Mountain spotted fever.—*R. E. Dyer.*

16647. **BARYKIN, W., A. ZACHAROFF, A. KOMPANEETZ, und O. BARYKIN. Untersuchungen über das Fleckfieber. II. Das Fleckfieber bei Kleiderläusen.** *Zentralbl. Bakt. I. Abt. Orig.* 112(1/2): 25-32. 1929.—Body lice allowed to feed on patients with typhus fever become infected from the 5th day of fever on. The optimum infective period is at about 2 wks., but infection may occur even 1 wk. after temp. has returned to normal. Guinea pigs can be infected experimentally by bites of infected lice. Infection is transmitted but rarely from one louse to another, but lice can be easily infected by injecting per rectum, an emulsion of the intestinal tract of an infected louse or of the brain of an infected guinea pig. The typhus virus undergoes enormous multiplication in a louse so infected, indicating that the louse is not merely a mechanical, but rather a biological, carrier. The disease is manifested in the louse after about 1 wk., by destruction of the intestinal epithelium and death after the 2nd wk. Virus carried thus from louse to louse retains its virulence.—*E. C. L. Miller.*

16648. **BEAUREPAIRE ARAGÃO, H. de, e A. da COSTA LIMA. Sobre a transmissão do virus de febre amarella pelas fezes de mosquitos infectados. [Transmission of yellow fever virus by excreta of infected mosquitoes.]** [In Portuguese and English.] *Inst. Oswaldo Cruz, Suppl. Mem.* 8. 101-108. 1 pl. 1929.—Excreta of infected mosquitoes are infective, although in the test cases *Macacus rhesus* monkeys recovered.

16649. **BEAUREPAIRE ARAGÃO, H. de, e A. da COSTA LIMA. Sobre o tempo necessario para que Stegomyias infectados excretem fezes virulentas. [Time required by infected Stegomyia to expel virulent excreta.]** [In Portuguese and English.] *Inst. Oswaldo Cruz, Suppl. Mem.* 9. 139-145. 1929.—The excreta of yellow-fever-infected mosquitoes are infective 5-7 days after the mosquito has bitten an infected *Macacus rhesus* monkey, although the bite is not infective for 9 days.

16650. **BEAUREPAIRE ARAGÃO, H. de, e A. da COSTA LIMA. Sobre o poder infectante da haemolympha de mosquitos contaminados com o virus da febre amarella. [Contamination of hemolymph in mosquitoes infected by yellow fever virus.]** [In Portuguese and English.] *Inst. Oswaldo Cruz, Suppl. Mem.* 10. 251-255. 1 pl. 1929.—The latent period before the bite of the mosquito becomes infective is explained by the time necessary for virus to pass from stomach to coelomic cavity and thence, by the hemolymph, to the salivary glands. By microscopic technique the authors removed hemolymph from an infected mosquito and inoculated a *Macacus rhesus* monkey, causing a fatal yellow fever.

16651. **DOOREN de JONG, L. E. den. Verdere onderzoekingen over den Megatherium-bacteriophaag. [Further investigations on Megatherium bacteriophage.]** *Nederlandsch Tijdschr. Hyg., Microbiol. en Serol.* 5(4): 259-262. 1931.—Only a few of the mutilates of *Bacillus megatherium* are lysed by *megatherium* bacteriophage 899. Cultivation of insensitive mutilates on 10% peptone agar renders more of them sensitive to this bacteriophage. Aside from *megatherium* strain 899, strains 897 and 333 also appeared to produce a bacteriophage; 899 and 897 appeared to form 2 sorts of plaques—one of the normal type and another with a small colony in the center of the plaque (point plaques). 333 and 897 attack fewer of the mutilates than does 899. Probably all *megatherium* strains produce bacteriophage.—*L. E. den Dooren de Jong.*

16652. **DYER, R. E., A. RUMREICH, and L. F. BADGER. Typhus fever. A virus of the typhus type derived from fleas collected from wild rats.** *U. S. Publ. Health Repts.* 46(7): 334-338. 1931.—Inoculation into guinea pigs, of fleas (*Ceratophyllus fasciatus* and *Xenopsylla cheopis*) removed from rats trapped at a typhus focus, resulted in establishment of a strain of virus producing typhus-like reactions in guinea pigs. Monkeys and rabbits developed agglutinins for *B. proteus* X_{19}

(type O) following inoculation with this virus strain. Guinea pigs recovered from endemic typhus produced by the Wilmington strain of virus were apparently immune to a subsequent inoculation with the strain of virus recovered from the fleas.—*Authors' summary.*

16653. **DYER, R. E., L. F. BADGER, and A. RUMREICH.** Rocky Mountain spotted fever (eastern type). Transmission by the American dog tick (Dermacentor variabilis). *U. S. Publ. Health Repts.* 46(24): 1403-1413. 1931.—A disease occurring in the eastern part of the U. S. A. has been identified as an eastern type of Rocky Mountain spotted fever. The common tick in the area where it has been studied in the East is *Dermacentor variabilis*. Experimentally, these ticks were infected in the laboratory by allowing them to feed as larvae on guinea pigs infected with the eastern type of the fever. After these larvae had moulted to nymphs the infection was recovered from the nymphs.—*R. E. Dyer.*

16654. **DYER, R. E., E. T. CEDER, A. RUMREICH, and L. F. BADGER.** Typhus fever. The rat flea, Xenopsylla cheopis, in experimental transmission. *U. S. Publ. Health Repts.* 46(32): 1869-1870. 1931.—Successful experimental transmission experiments with white rats, guinea pigs and rabbits are reported.

16655. **GERARDS, J. C.** Untersuchung der phagozytierenden Kraft der Leukozyten unter dem Einfluss des Bakteriophagen. *Zentralbl. Bakt. I. Abt. Orig.* 111(6/8): 493-496. 1929.—A stimulating influence of bacteriophage on phagocytosis is demonstrated both in vivo and in vitro and is shown to be specific. Serum of rabbits injected with bacteriophage is found to exert a similar influence, which is of short duration, on leucocytes from a normal animal.—*J. B. Nelson.*

16656. **HERRMANN, OTTO.** Plazentare Uebertragung der Wut. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 58(3/4): 371-383. 1928.—Many investigators have claimed that rabies is transmissible through the placenta. The author studied the question experimentally by inoculating animals with brain emulsion of fetuses from pregnant women that had died of rabies infection, and found that the virus is transmitted through the placenta in man as well as in animals. The virus in the brain of the fetus is generally decreased in virulence. Tests for presence of the virus in the fetus should be made by inoculating young rabbits and guinea pigs.—*D. Bergey.*

16657. **IONESCO-MIHAIESTI, C., A. TUPA, B. WISNER, et I. MESROBEANU.** Études sur la poliomyélite en Roumanie. (Premier mémoire: Epidémiologie. Étude du virus. Maladie expérimentale.) *Arch. Roumanies Pathol. Exp. et Microbiol.* 2(2/3): 217-274. Map. 1929.—Few sporadic cases of anterior poliomyelitis had been reported in Rumania in the 5-yr. period preceding 1927. An explosive outbreak occurred in Bucharest from July to November, 1927, with the peak in August (190 cases). Outside of Bucharest the epidemic occurred from August to December, 1927, with the peak in September (696 cases). Few cases were reported until the next summer, when there was another smaller rise. In the 2-yr. period there were about 2630 cases with 300 deaths. Materials from 8 cases in which death had occurred within 4 days after onset of disease, proved infective in monkeys. 5 specimens from cases in which death occurred 8-22 days after onset, proved non-infective on repeated injections into several animals. Later, inoculations with a virulent virus, in many of these latter animals, produced typical infections. The pathology of these 13 cases is given in detail. In the experimental infections the same incubation period was seen with 1 virus given to 4 animals. The incubation period varied from 6 to 14 days with different viruses. In general, it was prolonged after several virus passages. Detailed clinical and pathological studies were made of the experimental disease. Over 100 monkeys were used, belonging to 7 spp.; and it was confirmed that *Mac. rhesus, C. hamadryas* and *Mac. cynomolgus* are the most susceptible spp. In electrophoresis experiments, the virus, between pH 6.9 and 8.0, had a negative charge.—*E. Megrail.*

16658. **KLIENEBERGER, E.** Ein Stamm mit eigenartigen Abkömmlingen und der Zusammenhang des Auftretens solcher atypischen Abkömmlinge mit Bakteriophagie und Lysogenität. *Zentralbl. Bakt. I. Abt. Orig.* 112(5): 354-368. 1 pl. 1929.—From 1 original strain of colon bacillus there were produced during 2 yrs. culture, 8 distinct strains characterized as follows: (1) typical coli; (2) coli, no gas; (3) slimy coli, no gas; (4) paracoli; (5) paracoli, no gas; (6) typhoid-like; (7) paratyphoid-like; (8) coli mutabilis, no gas—all decidedly constant. The strains showed marked differences in serological reactions and insensitiveness to bacteriophage. A number of them were apparently markedly affected in cultural characteristics by bacteriophage. It was shown that these strains were already present in the original and appeared as colonies on plates because resistant to bacteriophage, which destroyed the far more abundant typical organisms; the appearance of all these new strains could be explained on this basis. Some of the strains developed their own bacteriophage. Any regular relation between gradual appearance of different strains and action of bacteriophage could not be detected, though resistance to bacteriophage and variability occurred together so frequently that it appears possible that ability to produce bacteriophage may be a factor in the production of variations.—*C. B. Morrey (from author's abstract).*

16659. **LAGRANGE, E.** L'autostérilisation mortelle de la peste aviaire d'Egypte est un phénomène épidémique. *Compt. Rend. Soc. Biol.* 106(12): 1081-1084. 1931.—Observations on fowl pox were made for 2½ yrs. (including 3 winters), during which time about 30 chickens were bought each mo. 3 brains which were immunizing in the fresh condition or after several days of refrigeration, became virulent after preservation in glycerin and in the refrigerator for 2 mo. The plague is a periodic, seasonal phenomenon, apparently not affected by autosterilization, which is a new factor. The fact that the virus which is virulent in the spleen, is immunizing in the brain, shows that it has followed its usual course and is only inhibited or destroyed in situ in certain organs afterward. Autosterilization is comparatively rare and is probably due to some antagonistic force in the chicken and not to the chicken itself, since it cannot prevent death or creation of foci of infection.—*E. Weiner.*

16660. **NICOLAU, S., (Mme.) L. KOPCIOWSKA, et (Mme.) V. CONSTANTINESCO.** Immunité et virus filtrables. Recherche par l'électrophorèse du virus herpétique dans le névraxe des lapins immunisés. *Compt. Rend. Soc. Biol.* 106(12): 1100-1103. 1931.—At different times (10-30 days) after intracerebral injection of herpetic virus, the brain and medulla of rabbits were removed and subjected to electrophoresis. The emulsion which became hardened on the positive electrode in each case was inoculated under the dura in 2 rabbits and that from the negative electrode in 1 rabbit. In every case the inoculated solutions were avirulent. It is concluded that the brain and medulla of rabbits immunized against herpetic virus do not contain virus which can be demonstrated by electrophoresis; the state of immunity in experimental herpetic infection of the rabbit is incompatible with the survival of the virus in the cerebrospinal axis. A. Netter, in a note attached to this paper, states that results of Olitsky and his collaborators are incontestable for the diseases tested: thrush, vaccinia and poliomyelitis; and that the discordant results of others may be due to changes in the constitution of the media in which the cataphoresis is done.—*E. Weiner.*

16661. **RAHN, OTTO.** Betrachtungen über die Natur der Bakteriophagen. *Centralbl. Bakteriol. II. Abt.* 83: 277-280. 1931.—The size of a bacteriophage unit is about the same as that of a gene. It is so small that it can not contain the complete growth mechanism of a bacterial cell. Therefore, its protoplasm must be similar

to that of its host, the bacterium. Only a few simple changes will probably produce bacteriophage protoplasm from bacterial protoplasm. Possibly, the bacteriophage is nothing but an unbalanced protoplasm molecule of the bacterium which has lost the adaption to the regulatory mechanism in the cell and continues to grow at the expense of the cell contents.—*O. Rahn.*

16662. **RUMREICH, A., R. E. DYER, and L. F. BADGER. The typhus- Rocky Mountain spotted fever group. An epidemiological and clinical study in the eastern and southeastern States.** *U. S. Publ. Health Repts.* 46(9): 470-480. 1931.—An epidemiological and clinical description is given of a disease occurring in the eastern part of the U. S. A., identified as an eastern type of Rocky Mountain spotted fever. It is differentiated epidemiologically and clinically from endemic typhus. Eastern spotted fever occurs among rural dwellers or those having rural contacts, in contrast to endemic typhus which occurs among urban dwellers and often among those closely associated with rats. A history of tick bite is commonly elicited from those with eastern spotted fever. The clinical features are compared with endemic typhus.—*R. E. Dyer.*

16663. **SIMMONS, JAMES STEVENS, JOE H. ST. JOHN, and FRANCOIS H. K. REYNOLDS. Transmission of dengue fever by Aëdes albopictus Skuse.** *Philippine Jour. Sci.* 41(2): 215-229. 1 pl., 1 fig. 1930.—The authors show that laboratory-bred *A. albopictus* can be as readily infected with dengue virus as can *A. aegypti*. *A. albopictus* is as common in the city of Manila as is *A. aegypti*. These facts suggest that *A. albopictus* is probably of great importance as a natural vector of dengue in Manila and elsewhere.—*J. H. St. John.*

16664. **TAKAHASHI, KENSABURO, und SOYO HOSHIZAKI. Einiges über die experimentelle Reinfektion von Meerschweinchen mit Fleckfieber. IV. Experimentelle Studien über das Fleckfieber.** *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 39-40. 1931.—Of 46 guinea pigs, reinfected during the 127 days after the 1st typhus infection, 10 showed the clinical signs of experimental typhus; the incubation time was longer, the febrile period shorter. In some animals typhus nodules were found in the brain, apparently called forth by the reinfection.

16665. **TAMURA, S. Die Prowaczek'schen Körperchen bei Trachom in Taiwan.** *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 309. 83. 1930.—The author demonstrated these bodies in 21.2% of 242 cases of trachoma in Formosa.—*E. C. Faust.*

16666. **TAYLOR, J., S. D. S. GREVAL, and U. THANT. Bacteriophage in bacillary dysentery and cholera.** *Indian Jour. Med. Res.* 18(1): 117-136. 1930.—26 cases of bacillary dysentery were treated with a bacteriophage of high activity. No significant difference was observed in the progress of these cases, either in mortality or in shortening of the period of attack, as compared to 20 control cases. No relationship was shown between appearance of bacteriophage in the stools and progress of the cases. Similar results were obtained in 14 cases of cholera treated with bacteriophage (with 19 controls). The authors conclude that bacteriophage is not essential to recovery and that it is not an effective therapeutic agent in the class of cases dealt with.—*J. Taylor.*

16667. **VEDDER, A. Zur spezifischen Lysabilität von Erysipelstreptokokken.** *Acta Brevia Neerlandica* 1(1): 27-28. 1931.—Earlier, the author showed erysipelas streptococci to be lysed only by the bacteriophage of Schwartzman; hemolytic streptococci of other origin have proved resistant. But only smooth strains of erysipelas cocci, producing considerable turbidity and forming rather short chains in broth, were sensitive to this bacteriophage; rough strains showing longer chains and a deposit in broth, which itself remained clear, were resistant. As hemolytic streptococci of other origin grow like the latter, the question arose as to whether these strains owed their resistance against lysis to their rough state or to a specific character. New streptococcic strains of scarlatinal, puerperal and of other origin were examined. Some grew like the smooth strains, but were resistant to lysis. Thus, the lysability of erysipelas streptococci does not depend on their smooth state only, but is a specific character.—*A. Vedder.*

LOWER ANIMALS

16668. **BEATON, W. G. Infectivity of shade-dried hides from rinderpest infected cattle.** *Vet. Jour.* [*London*] 87(11): 532-533. 1931.—Hides from animals affected with rinderpest remained infective as long as 36 hrs., but not to the 48th hr., when dried in the shade.—*I. E. Newsom.*

16669. **ELS, T. La peste bovine à la frontière orientale du Congo Belge.** *Bull. Agric. Congo Belge* 21(4): 1029-1047. 2 pl., 1 fig., map. 1930.—During an outbreak of bovine plague (rinderpest) in the West Nile District near the Congo-Sowdanaise frontier, a vaccine prepared with an autochthonous strain of virus according to the technique of Curasson was used. Of the 2,130 animals vaccinated, 14 died of plague and 4 cows aborted. The rest remained healthy.—*L. M. Bishop.*

Exotique* 22(4): 239-241. 1929.—Rinderpest can maintain itself in a form not clinically evident, in animals considered resistant to its attacks or in animals immunized against it. These animals play an important part in propagating the disease.—*L. R. Bishop.*

BACTERIOLOGY AND OTHER MICROBIOLOGY

MEDICAL

JAMES S. SIMMONS, *Editor*

(See also in this issue Entries 15582, 15769, 16104, 16158, 16262, 16301, 16322, 16328, 16330, 16331, 16338, 16339, 16349, 16381, 16388, 16398, 16435, 16436, 16451, 16453, 16459, 16461, 16465, 16485, 16495, 16504, 16519, 16524, 16543, 16547, 16633, 16652, 16746, 16749, 16754, 16757, 16760, 16766, 16767, 16771)

16671. **ALMEIDA, FLORIANO PAULO de. Estudo comparativo do Granuloma coccidioidico nos Estados Unidos e no Brasil. [Comparative study of Coccidioidal granuloma in the United States and Brasil.** [With English summary.] *Ann. Fac. Med. São Paulo* 4: 91-98. 4 pl. 1929.—The author reports studies of various aspects of the parasite of coccidioidal granuloma observed in the U. S. A. and Brazil, and summarizes the principal differences found in the 2 countries. Considering these differences, he proposes for the parasite of the Brazilian cases the name *Coccidioides* **brasiliensis** (*Zymonema brasiliense* Splendore). A tabular comparison of the features of the disease and the causal fungi, as reported in the U. S. A. and in Brazil, covers the following features: portals of entry, principal bodily localizations, dimensions of the fungus, reproduction in the tissues, cultures and cultural characters, and inoculations. In the U. S. A., positive results were easily obtained in guinea pigs with any mode of inoculation, and with generalization of lesions; in Brazil, infections were obtained with difficulty, except by the testicular route, and then only local lesions occurred.—*From author's summary.*

16672. **BENEDEK, T. Schizosaccharomycosis. I. The present status of identification of Schizosaccharomyces hominis and its results.** *Arch. Dermatol. and Syphil.*

24(4): 557-579. 9 fig. 1931.—The discoverer of *S. hominis* reports that in 28.02 ± 3.39% of 1500 cases the fungus was identified by cultures from scales of the skin, a method which identifies only such individuals as have left the vascular system, and, traversing the skin and epidermis, have settled on the surface. Through direct blood cultures, *S. hominis* was identified in 17.48 ± 8.1 of 206 cases, the low % being due to the high inhibitive action of whole blood. Through indirect blood cultures (cantharidin method) the parasite was identified in 66.55 ± 8.5% of 279 cases. If the contents of the blisters are examined microscopically and evaluated, the positive cultures increase to approximately 100%, since multiplication is conspicuous within 24 hrs. Centrifugalization of the citrated blood shows the degree of invasion of the blood stream at a given moment by *S. hominis;* it can be identified in the blood stream in the vegetative form and also phagocytosed by microphages and macrophages. By this method the author also demonstrated *S. hominis* in the venous blood of the umbilical cord, proving transplacental transmission from mother to fetus. *S. hominis* is a constant endoparasite of man, and the dermatoses caused by it are merely "projections" of this endoparasitism on the outer surface of the integument.

16673. **FONTES, A. Ueber die Veränderlichkeit des Tuberkelbazillus.** *Tuberkulose* 10(11): 255-258. 1930.—On the basis of clinical and experimental studies begun in 1906 the author concludes that the chromatin granules found in the bacterial cells are living units of reproduction and infection, and that tuberculosis virus passes through 3 stages: (1) germinative (granular dust, free granules); (2) growing (enlargement of the granule, organization of the acid-fast bacilli); and (3) fission or destruction (splitting of cells, freeing of granules). He declares that the existence of tuberculous infection without acid-fast bacilli and without formation of tubercles is an assured fact. The classic infection of which the acid-fast Koch bacillus is the recognized cause is, in this view, merely the critical point in a process which may lead to formation of tubercles or (as lately demonstrated) to a resorptive change in which the invading organism becomes non-acid-fast and saprophytic. The author claims to have produced a similar change in vitro, acid-fast bovine tubercle bacilli becoming non-acid-fast and gram-negative; and to have kept virus alive in vitro for 2 yrs., 7 mos. A new curative principle (apparently extracted from the bacteria and tending to produce this saprophytic change) is for the present designated as Agent X because the author does not assume to know that it is a "ponderable body."

16674. **HERELLE, F. d', R. H. MALONE, and M. N. LAHIRI. Studies on Asiatic cholera.** *Indian Med. Res. Mem.* 14. 1-161. 6 pl. 1930.—The viability of the cholera vibrio in water is very weak; usually all died in less than 48 hrs. The biochemical properties of the cholera vibrios studied are fixed. The following sugars are attacked with production of acid only: glucose, mannite, saccharose, and maltose; all gave the nitroso-indol reaction, reduced nitrates, and hemolyzed human erythrocytes. Vibrios cultivated outside the body are generally avirulent, but virulence may be reacquired when certain conditions are realized. We are in ignorance of the toxigenic power. Filtrates obtained directly from stools of patients should be made to act on the original culture of vibrios isolated from the stool of the same patient. The general characters of bacteriophages parasitic on cholera vibrios are the same as those of other bacteriophages already discovered and the technique of isolation is the same. In the intestines of patients attacked by cholera, both vibrios and bacteriophages possess individuality which is lost, in both cases, by serial cultures on artificial media. For cholera to declare itself, virulent vibrios must invade and multiply within the intestinal mucosa. Virulent cholera vibrios secrete enzymes capable of digesting the living substance of cells, and powerful hemolysins for human erythrocytes. The pathology of the disease results from the action of the vibrio, tending to produce fatal lesions and the intestinal bacteriophage of *B. coli* adapting itself to the pathogenic vibrio. The vibrio and bacteriophage being present together, 4 events may take place: (1) the intestinal bacteriophage adapts itself rapidly to parasitism for the invading vibrio: the symptoms, however severe at onset, rapidly improve and the patient becomes convalescent. (2) the intestinal bacteriophage adapts itself more slowly, but attains a high virulence: convalescence is established as soon as bacteriophagy occurs in vivo. (3) after a primary exaltation, the feeble virulence acquired by the bacteriophage becomes attenuated and disappears: after temporary amelioration of symptoms the patient's condition again becomes aggravated and death ensues, (4) the bacteriophage manifests no virulence for the vibrio: no improvement of the symptoms takes place and the patient rapidly succumbs. The action of the bacteriophage is exercised in 3 different ways, all tending to recovery: (1) the bacteriophage produces bacteriophagy in vivo. (2) the bacteriophage modifies the character of the vibrios so that a secondary culture is completely avirulent. (3) the bacteriophage produces lysis of bacteria by secretion of "lysins" which also possess opsonic power. From experimental treatments it is concluded that the administration per os (never by the subcutaneous route) of bacteriophages possessing high virulence for cholera vibrio, constitutes the specific treatment of Asiatic cholera. Observations show that cessation of epidemics of Asiatic cholera is due to diffusion from convalescents of bacteriophages adapted to effect the bacteriophagy of cholera vibrios, and that it is possible to reproduce this process experimentally by sowing selected cultures of bacteriophages in the wells of infected villages. This method is easily applied, is inexpensive, and causes least inconvenience to the population.—*P. L. Cummings.*

16675. **KADISCH, E., und A. DOEWY. Über den Verlauf der Infektion mit Achorion gypseum im Höhenklima. Ein Beitrag zur Frage des Sauerstoffbedürfnisses der Fadenpilze.** *Arch. Dermatol. u. Syph.* 163(1): 149-157. 11 fig. 1931.—The course of experimental infection of a guinea pig with *A. gypseum* changed with increasing altitude: (a) the incubation period was 8-10 days instead of 4; (b) the initial and the developed infection was less marked, i.e., infiltration, extent, and scale and scab formation were slighter; (c) the mold elements seemed to be less numerous in altitude animals and did not penetrate so deeply. From published in vitro experiments the authors assume that these phenomena are related to the decreasing O partial pressure. Once, in an animal transported from Davos to Berlin, on the 15th day after infection, a ring-shaped recurrence appeared, explained by the hypothesis that at the time of transportation a local, but not general, allergy had already formed; thus the original central disease was cured, while around it there was a relapse. These results show a further parallel between trichophytia and tuberculosis. Temp. and air supply determine the localization of mycoses. Temp. and air supply, however, have values deviating from the interior of the body in the lungs as well as on the skin. Lungs and skin are therefore to be suspected as sites of predilection for tuberculosis, for temp. and air supply can also play a part in the localization of tuberculosis. The milder course of mycoses in guinea pigs at high altitudes represents perhaps in miniature a parallel to the effect of a high mountain climate on pulmonary tuberculosis.

16676. **KAHN, MORTON C. A growth cycle of the human tubercle bacillus as determined by single cell studies.** *Tubercle* 11(5): 202-217. 4 fig. 1930.—The author isolated single cells to start stock cultures, and again isolated single cells from these for study. Micro-droplets containing 1-6 bacilli were placed on cover slips and kept in special glass moisture chambers for several days up to a few weeks, observations being made very frequently. At certain stages in development, stained preparations were made, to find their reaction toward the acid-fast stain. After a few hrs. at 37° C., the rods develop certain dark zones. At 24-72 hrs. after isolation, lines of cleavage appear, without reference to the dark

zones, and the original rod is segmented into 3 or more ovoid units. At this period the ovoid forms are usually acid-fast, but some of them are only surrounded by an acid-fast zone. These coccoid forms then subdivide by simple cleavage into very small coccoid forms, some of which form short chains and diplococci. These forms are found to be non-acid-fast. After another 24 hrs. these small granules tend to form clumps and soon these small forms become dust-like granules too small to distinguish. After 24-96 hrs., small, very delicate rods, mostly non-acid-fast or very slightly acid-fast, are seen developing from these dust-like clumps. These rods gradually thicken and grow into adult acid-fast rods. Several unusual forms, such as branched bacilli with dark zones, granules breaking from rods, and fine rod-like processes growing from dark zones in the bacilli, were also observed, but they did not seem to be part of the usual life cycle. The 4 principal steps in the life cycle seem to be (1) division of the rod into 3 or more coccoid units which then (2) divide into diplococcoid forms, then (3) group themselves into dust-like groups from which new tiny rods emerge, growing again (4) into adult rods.—*F. Stivers.*

16677. **MONTEIRO, J. LEMOS. Sobre a presença de Rickettsia brasiliensis n. sp. nas cellulas endotheliaes da parede peritoneal em cobaias innoculadas no peritoneo com o virus do typho endemico de S. Paulo. [Presence of R. brasiliensis n. sp. in endothelial cells of the peritoneal wall in guinea pigs inoculated in the peritoneum with the virus of endemic typhus.]** [With English summary.] *Brasil-Med.* 45(35): 805-807. 1 fig. 1931.—The author reviews the relation between the members of the *Rickettsia* group and the pathological varieties of exanthematic typhus and allied infections. Rickettsias occur in the endothelial cells of Descement's membrane and may also occur in the endothelial cells of the peritoneal wall as a result of virus inoculation into the peritoneum of guinea pigs. Based on the etiological and immunological relations between this *Rickettsia* and the form found in the typhus endemic in São Paulo, the name of *Rickettsia* **brasiliensis*** (p. 806) is proposed. Microorganisms indistinguishable from the rickettsias appear in the endothelial cells of the peritoneal wall of guinea pigs peritoneally inoculated with the São Paulo endemic typhus virus.—*Author's summary.*

16678. **NAGAYO, MATARO, YONEJI MIYAGAWA, TOKUSHIRO MITAMURA, TAKEO TAMIYA, KIYOSHI SATO, HIKOZAEMON HAZATO, und ARAO IMAMURA. Über den Nachweis des Erregers der Tsutsugamushi-Krankheit, der Rickettsia orientalis.** *Japanese Jour. Exp. Med.* 9(2): 87-150. 13 pl. (4 col.), 1 fig. 1931.—There is considerable dispute as to the cause of tsutsugamushi disease. The authors, in very elaborate and extensive experimental work, claim to have furnished conclusive evidence that the cause is *Rickettsia orientalis.* Intraocular inoculation of the virus invariably produces a specific disease of the eye, and in the endothelial cells of Descemet's membrane the micro-organism can invariably be found. *R. orientalis* is identical in every respect with the organism isolated from the tissues of tsutsugamushi cases, as well as with the virus from experimentally infected animals. Inoculation of the endothelial cells of Descemet's membrane harboring the microorganisms even in small amounts, induces a severe infection. Introduction of virus-containing material into eyes immune against the disease induces no infection and the microorganism can not be recovered following such inoculations. The histological changes in the eye induced by the virus are identical with those found in natural cases or with those produced experimentally in animals.—*A. Eichhorn.*

16679. **PACHECO, GENESIO, e F. CARNEIRO de MENDONÇA. Um anno de investigações nas dysenterias do Rio de Janeiro. (One year's investigations on the dysenteries of Rio de Janeiro.)** [With French and English summaries.] *Archivos Hyg. [Rio de Janeiro]* 4(1): 5-39. 1930.—Results of an investigation made on stools of suspicious cases of dysentery show that diagnosis of probability by the cellular test, by presence of mucus, or by type of stools, is not likely to replace bacteriological diagnosis, for clinical and hygienic orientation. Identification of the samples was based on investigations of the sugar-fermenting organisms, on the neutral-red change, and on the action of agglutinating sera prepared from known samples.

16680. **SAUNDERS, EDWARD WATTS, with the technical assistance of MARY A. COOPER. Is there a specific bacterial irritant to four sites of carcinoma?** *Amer. Jour. Cancer* 15(4): 2745-2755. 1931.—A streptococcus isolated by anaerobic tissue cultures from stomach, colon, breast, and cervix in disease was shown to be pathogenic on isolation, then to pass through various stages, on environmental changes, from smooth to rough, to lose its pathogenicity, and to become morphologically, biologically, and serologically identical with enterococci, which are closely related to, or identical with, *Streptococcus lacticus* of cows' milk. Its greatest viability and resistance to heat above that of pasteurization, are noted. Its lactic acid production and pH range are also noted specifically because of the metabolism of the carcinoma cells, as demonstrated by Warburg. Its H_2S production is noted because of Hammett's work in demonstrating that S in the reduced state, which occurs at pH 5.5 or lower, is the chemical stimulus to cell division. The acid range of this organism is 4.2-4.8, which, according to Hammett, would result in maintaining S in the suboxidized state, stimulatory to cell division. Agglutination tests of patients' serum against an antigen of several of the identical strains demonstrated circulating antibodies. Definite microbic dissociation was demonstrated. A hypothesis is formulated, that the chronic ulcerative lesion of long duration, which finally starts to show proliferative activity and uncontrolled cell division, may be due to: (1) continuous repair; (2) poor blood supply and lymph return; (3) presence of the streptococcus, which is characterized by (a) remarkable viability, (b) lactic acid production, (c) H_2S production, (d) anaerobiosis. As a result of these 4 major characteristics, there is brought about a pH value and an oxidation-reduction potential in which the sulphydryl group, present in all tissues in the form of cystein and glutathione, is stimulatory to cell division.—*Author's summary.*

16681. **VELU, H., L. BALOZET, et G. ZOTTNER. Apparition de la virulence du cerveau chez les cobayes inoculés avec le spirochète hispano-marocain.** *Compt. Rend. Soc. Biol.* 106(12): 1089-1091. 1931.—10 guinea pigs were inoculated by putting a drop of blood containing *Spirochaeta hispanicum* in the eye. They were killed by ether at different times after inoculation and the virulence of brain and spleen was tested by subcutaneous injection into other guinea pigs and the blood examined for presence of spirochaetes. Both organs became infective at the same time, which was little before appearance of spirochaetes in the blood. To show the effect of injuring tissues, 5 guinea pigs were inoculated in the same way and 5 intraperitoneally. The spleen and blood were infective in every case, even when examined only 12 hrs. after inoculation intraperitoneally; but with the other method, this occurred later and irregularly. The brain became virulent after the blood and spleen, and organisms appeared in the blood stream still later. The left hemisphere was inoculated and the virulence of the right hemisphere, spleen and blood were studied in 7 guinea pigs after 6 hrs. to 4 days. Results were inconclusive, all the organs being infective in every case. The affinity of the central nervous system for these spirochaetes is shown only by its retention of the organisms or by their persistence in the organ because of its lack of a means of defense.—*E. Weiner.*

16682. **WEIGMANN, F. Experimentelle Untersuchungen über die Beziehungen zwischen Bact. abortus Bang und Bact. melitense.** *Zentralbl. Bakt. I. Abt. Orig.* 121 (5/6): 318-328. 3 fig. 1931.—In confirmation of Huddleson's findings, it is shown that gentian violet makes possible a differential medium for Bang's bacillus, since it inhibits various closely related organisms, but not this

bacillus. *Bact. abortus,* both bovine and human strains, were inhibited by thionin but not by methyl violet. With *Bact. melitense* and *Brucella suis* the opposite is true. *Bact. melitense* is pathogenic for monkeys (*Macacus rhesus*) which show a temp. curve similar to that in man, while human or bovine *abortus* strains are only pathogenic in large doses. By absorption of agglutinins no differences could be detected among several old laboratory strains of *Bact. abortus* and *Bact. melitense,* although the latter is more resistant to bactericidal action of normal human serum. If one takes into consideration the fact that *Bact. abortus,* on primary isolation, grows only under a modified O tension (atmosphere of CO_2, illuminating gas), while *Bact. melitense,* according to the author's work, grows under ordinary aerobic conditions, it is seen that a differentiating distinction of types within the *Brucella* group exists. On the other hand, by treating white mice with killed vaccines of either type, protection against infection with both homologous and heterologous types is demonstrated. 2 monkeys which had been infected with live cultures of *abortus* and *melitensis* strains, respectively, were later inoculated with 4 times the infecting dose in the reverse order; no symptoms of illness developed. The intracutaneous reaction is the same with both types of antigen (abortin and melitensin) regardless of which strain is responsible for infection. Inoculation of goats with human strains of *abortus,* either subcutaneously or per os, produces no noticeable symptoms. The organisms could be recovered only from the inoculation site, and no change to the *melitensis* type was noted. Inoculation of various experimental animals (guinea pigs, monkeys, goats) results in production of agglutinating and complement-fixing antibodies. Agglutinating titers were equally high for *abortus* and *melitensis* strains. An abortus strain isolated from the blood of a patient could not be differentiated from bovine strains.—*F. Weigmann* (*transl. by L. Thompson*).

16683. WINGE, KNUD. Über den klinischen Nachweis des Tuberkelbazillus durch Züchtung auf Substrat und durch Tierversuche. *Acta Tuberc. Scandinavica* 5(1): 37-85. 1929.—The experiments included comparative investigations on the same material between cultures and animal experiments in the form of intracutaneous and intraperitoneal inoculations into guinea pigs. The material examined included expectorates, clear and turbid pleural exudates, joint exudates, urine and spinal fluid. In group I are examined the yields of the different methods applied to the material, in which direct microscopy had revealed tubercle bacilli. In 20 of 24 experiments, glycerinated potato yielded growth within 13-46 days (mean 25 days), Petroff's substrate gave growth 23 times within 9-47 days (mean 13 days), and Hohn's substrate 24 times within 9-19 days (mean 13). In 23 of the animal experiments, intracutaneous inoculation yielded positive results within 7-17 days (mean 13). Autopsy of the guinea pigs performed 6 weeks after infection revealed tuberculosis in all of them. In group II were employed tubercle bacillus elutriations in different dilutions. In a dilution of 1: 10,000, bacilli could still be demonstrated in animal experiments and on Petroff's substrate. Group III comprises all the experiments in which tubercle bacilli could not be demonstrated by direct microscopy. In 41 of 59 experiments, bacilli were detected in animal experiments, and 34 times in cultures. In 7 cases, animal experiments yielded positive results, whereas the substrates failed to give results. In 1 case, 2 of the substrates gave growth of tubercle bacilli, whereas the animal experiment failed to do so. The several methods yielded the following results: Glycerinated potato gave growth 21 times within 15-65 days (mean 14 days); Petroff's substrate yielded 31 positive results within 10-51 days (mean 24 days) and Hohn's substrate gave growth 30 times within 10-40 days (mean 22 days). In the animal experiments, autopsy of guinea pigs 6 weeks after infection revealed tuberculosis in 41 of 42 cases which, in spite of the negative result obtained by direct microscopy, contained tubercle bacilli. The intracutaneous test gave 31 positive results within 7-33 days (mean 22 days). As the results of neither animal experiments nor cultures are absolutely reliable, both methods should be employed for demonstration in case direct microscopy fails. In animal experiments, intracutaneous inoculation frequently enables one to make an early diagnosis.—*K. Winge.*

16685. BRESLER, FRITZ, und HERBERT LUBINSKI. Die Bestimmung des Chlorgehaltes in eisenreichen Wässern. *Arch. Hyg. u. Bakteriol.* 106(4): 197-208. 1931.—In water containing 50-100 mgm. of Fe per liter the author suggests addition of 5-10 cc. of cold, saturated Na acetate solution to each 100 cc. of water tested, thereby reducing the acidity sufficiently for Mohr's test, and avoiding the necessity of precipitating and filtering off the Fe.

16686. CASARINI, ARTURO. La medicina militare nella leggenda e nella storia. [Military medicine in legend and history.] *Gior. Med. Militare* 20: 1-688. 154 fig. 1929.—The spirit which animates the volume rests on the conception that one must not study the history of medicine as of antiquaries; several false directives which have ruled the development of medical sciences in the course of the centuries would not have arisen if the investigators, medical and biological, had had the knowledge of history and had appreciated it in its true value. One must consider the historical studies in question not as objects of specialization but as objects of synthesis. In a rapid but sufficient incursion across the centuries the author attempts to place in evidence the sources, not many, which can be arranged for the history of military medicine (Ancient Orient, Rome, Middle Ages, Renaissance, 17th and 18th centuries, Napoleonic Period, Ancient Italian States, Great War), and to deduce the general practical conclusions. An appendix gives a glance at the Italian military sanitary services since 1870 and at the services of assistance to those sick and injured in war.—*G. Tegoni* (*transl. by G. G. DeBord*).

16687. CARNES, E. H. Rat-flea survey of the port of St. Thomas, Virgin Islands. *U. S. Publ. Health Repts.* 46(43): 2558-2562. 1931.—The survey (July 1, 1929, to June 30, 1930) yielded 312 rats, from which 2,113 fleas were taken: *Xenopsylla cheopis* and 5 *Ctenocephalus canis* or *felis.* The average rat-flea index for the period was 6.7. The *cheopis* index was high throughout the yr., but relatively highest during summer (March-September, inclusive) and varied in direct relation to temp. and rainfall. *Rattus alexandrinus* was the predominating rat; *R. norvegicus* was found. Should plague be introduced, it would probably spread rapidly, as all conditions appear favorable.

16688. COLLINS, SELWYN D., W. H. FROST, MARY GOVER, and EDGAR SYDENSTRICKER. Mortality

from influenza and pneumonia in 50 large cities of the United States, 1910-1929. *U. S. Publ. Health Repts.* 45(39): 2277-2328. 1930.—This report deals with influenza and pneumonia mortality in the 50 cities with 100,000 or more population in 1910. For 35 of these cities, with an aggregate population of nearly 25,000,000, deaths from influenza and pneumonia are available by weeks from September, 1918, to date of writing. Deaths for the country as a whole are not available by weeks, so that these data for this large group of cities has considerable significance. To supplement them, monthly influenza and pneumonia death rates have been computed for the same cities for 1910-1918. Since 1915 there have occurred 10 distinct periods, each 8-13 wk. in duration, in which the mortality from influenza and pneumonia in this group of widely dispersed cities was so greatly increased as to denote epidemic conditions. Minor epidemics prior to the 1918 pandemic occurred in January, 1916, January, 1917, and April, 1918, with a very slight rise in mortality in April, 1915, also. We are accustomed to think of the epidemic of 1918 as occurring in the fall, and it is true that the enormous peak, at mid-October, overshadowed all prior and subsequent epidemics. In addition to this tremendous peak, the epidemic stretched over a period of 31 wk., from September 15, 1918, to April 19, 1919, and as late as the latter part of January, 1919, mortality from influenza and pneumonia in excess of the expected rates at that season was greater than the excess mortality during the epidemic of 1929. In the early months of 1920, a very sharp epidemic occurred, with excess mortality greater than during any other epidemic since the 1918 pandemic. In February, 1922, February, 1923, March, 1926, and January, 1929, other epidemics occurred, and in May of 1928 there was a slight rise in influenza mortality extending to many sections of the country. The combined excess mortality from influenza and pneumonia during these 6 epidemics that have occurred since the pandemic of 1918 was somewhere near ½ that of 1918-1919. In addition to data for these cities, this report contains monthly excess death rates for each of the 50 cities for 1910-1929 and weekly excess death rates for a large number of the cities during the 3 major epidemics, 1918-1919, 1920 and 1928-1929. In all of the epidemics, there is a great variation in severity in different cities. Moreover, there are periods of excess mortality from influenza and pneumonia in certain cities and sections of the country, which are not of sufficient importance to show in the combined data for the country as a whole. The report is intended as a rather detailed history of influenza and pneumonia mortality during 20 yrs., as a background for consideration of the situation with respect to the respiratory diseases at date of writing.—*S. D. Collins.*

16689. CRAMER, ROBERT. The rôle of protozoa in activated sludge. *Industr. and Engineer. Chem.* 23 (3): 309-313. 4 fig. 1931.—Clarification of sewage was investigated under aerobic conditions maintained by dissolving 0.3% $NaClO_3$ in 100 cc. cultures. Raw sewage clarified in 2-4 days, producing sediment not distinguishable from activated sludge, when bacteria and protozoa were present and the surface was exposed to air, but not in absence of any one of these conditions. Inoculation with 1 drop of activated sludge hastened clarification. Keeping cultures at 20° C. caused clarification in about ⅓ the time required at 10°. Omission of $NaClO_3$ caused putrefaction; addition of 0.05% prevented it.—*R. Cramer.*

16690. CRICHLOW, N. The prevalent diseases of the British Solomon Islands. *Trans. Roy. Soc. Trop. Med. and Hyg.* 23(2): 179-184. 1929.—Widespread diseases are: malaria, chiefly benign tertian; pulmonary diseases, which cause 16-20% of the total deaths; tuberculosis; dysentery, chiefly bacillary, responsible for a heavy death rate; yaws, the commonest disease. Intestinal worms are widely prevalent. Gonorrhea is not uncommon, but syphilis has not been found. Other diseases are reported.—*H. Kirby, Jr.*

16691. COLLINSON, JOHN, and CLARA COUNCELL. Whooping cough in Maryland. *Maryland Dept. Health, Bur. Vital Statistics Bull.* 1. 1-16. 1931.—In this study of whooping cough in Maryland, 1921-1929, it is shown that the mean rate per 100,000 population of reported morbidity was 246.4 and that the mortality was 10.7. This death rate is higher than that in the Registration States of 1910 during the same period. The rate of mortality in Maryland was higher in the female than in the male sex, and in the negro than in the white race. 12% of the cases and 56% of the deaths were among infants under 1 yr. old. 55% of the cases and 96% of the deaths were in those under 5 years old. The peaks of morbidity and of mortality occurred during March. Age, sex, color and seasonal distribution have not varied markedly in years of high or low prevalence. Death rates from whooping cough in the counties of Maryland have been almost consistently higher than those in Baltimore City since 1906. In the different counties there is a wide degree of variation in rates and there is apparently no relation between prevalence in the negro and white races. During the preceding 24 yrs. there was a slight downward trend in death rates from this disease.—*J. Collinson.*

16693. DOHRN, K. Leitfaden der Gesundheitsfürsorge: für Fürsorgerinnen und alle in der Wohlfartspflege tätigen Personen. [Guide in sanitation for those engaged in health welfare work.] 147p. Johann Ambrosius Barth: Leipzig, 1931. Price 4.60 M.

16694. DYER, R. E., E. T. CEDER, R. D. LILLIE, A. RUMREICH, and L. F. BADGER. Typhus fever. The experimental transmission of endemic typhus fever of the United States by the rat flea Xenopsylla cheopis. *U. S. Publ. Health Repts.* 46(42): 2481-2499. 2 pl. 1931.—Epidemiological evidence rules out the tick, bed bug, head louse and body louse as possible vectors, and incriminates some blood-sucking parasite of rats. The authors report successful infection of *X. cheopis* with the virus and experimental transmission of the disease from rat to rat by this flea. Typhus virus has also been repeatedly recovered from feces of infected fleas. Brain lesions found in guinea pigs infected with endemic typhus are described. The evidence presented points to *X. cheopis* as a common vector of endemic typhus from rat to rat and from rat to man.—*R. E. Dyer.*

16695. ELLICOTT, V. L., and CHARLES H. HALLIDAY. The psittacosis outbreak in Maryland, December, 1929, and January, 1930. *U. S. Publ. Health Repts.* 46 (15): 843-850. 1931.—24 cases of psittacosis occurred in Baltimore and 12 in the counties of Maryland during the outbreak of 1929-30; 5 were fatal. 5 cases occurred among a total of 33 pet shop employees; 4, among 21 persons exposed to human cases but not to infected birds; and 2, among health department employees. Of 12 pet birds in homes prior to the outbreak and which became associated with infected parrots brought into these homes, 6 died.—*V. L. Ellicott.*

16696. FLOOD, G. M. Sewage disposal from isolated buildings. 257p. 125 fig. Sutherland Publ. Co., Ltd.: Manchester, 1929. Price 12s.—After discussing the underlying theories of sewage disposal and purification, the author describes the design and construction of septic and sedimentation tanks, filters, chemical and dry closets, and distributing systems.—*W. N. Sparhawk.*

16697. HASSELTINE, H. E. Prevalence of undulant fever in the United States. *U. S. Publ. Health Repts.* 46(26): 1519-1523. 1931.—Data compiled from reports of state health authorities (32 states) give the reported cases by mo., for 1929 and 1930. Minima occur in Jan., Feb. or Mar.; maxima in July (1930) or September (1929).

16698. HASSELTINE, H. E., and I. W. KNIGHT. Outbreak of undulant fever traced to infected milk supply. *U. S. Publ. Health Repts.* 46(39): 2291-2300. 1931.—6 cases of undulant fever in a community of 5,300, between September 1, 1930, and January 9, 1931,

all used raw milk supplied by 1 dealer who produced most of the milk that he sold. This herd consisted of 42 animals. 24 gave serologic evidence of infection with *Brucella*. In February, 1931, milk samples were obtained from 6 of the reacting cows remaining on the premises and from 2 of them *Br. melitensis* var. *abortus* was isolated in 2 different laboratories. On January 9, 1931, the State Department of Health required the dealer to discontinue sale of raw milk until all reacting animals were removed from the premises, or, as an alternative, that all milk sold from the premises should be pasteurized. The dairyman pasteurized all milk from January 10, 1931, until the last of the reacting animals were eliminated from the herd, in May, 1931. No case of undulant fever occurred among the consumers of this herd's milk after pasteurization was put into effect.—*H. E. Hasseltine.*

16699. **HERB, O. Absorptionsversuche mit belebtem Schlamm.** *Archiv Hyg.* 100(1/4): 112-120. 1928.—Experimental data and observations reported indicate that treatment of different types of sewage with activated sludge gives the same results that were obtained with the old oxidation treatments. They also show that Dunbar's absorption theory is applicable to activated sludge. Clarification of sewage depends on absorption ability as well as on kind of bacteria and ferments in the activated sludge. 25° C. is the optimum temp. for clarification of sewage with activated sludge.—*B. Domogalla.*

16700. **HOLSENDORF, B. E. An important source of original rat infestation on newly constructed vessels.** *U. S. Publ. Health Repts.* 46(33): 1943-1945. 1931.

16701. **HUDDLESON, I. FOREST. Étude sur les infections à Brucella observées à Tunis et à Malte.** *Arch. Inst. Pasteur Tunis* 19(4): 391-421. 2 pl., 1 fig. 1930.—The rapid agglutination test appears to be as accurate and specific for serodiagnosis of undulant fever in Mediterranean countries as is the test tube method. Isolation of *Br. melitensis* from human blood can be accomplished with much more ease and higher success if a special medium such as beef or veal liver infusion bouillon be used. The time interval between inoculation and initial growth of *Br. melitensis* from blood averages about 72 hrs., but occasionally 15-days' incubation is required for initial growth. The pyretic period is most favorable for culturing the organism from blood. Delay in inoculation of medium after procuring blood specimens postpones initial growth. There is no evidence that the disease in man in Tunis and the Maltese Islands is caused by a *Brucella* other than *Br. melitensis*. The disease in goats in Mediterranean countries differs from that in cows in the U. S. A., in that it is of a more generalized nature and in that the premature expulsion of the fetus commonly associated with the disease in cows does not often occur. Human infection with *Br. melitensis* in Tunis and in the Maltese Islands is on the average more severe and of longer duration than is human infection with *Br. abortus* in the U. S. A.—*I. F. Huddleson.*

16702. **HUDGINS, BERT. Turbidity, plankton, and mineral content of the Detroit Water Supply.** *Jour. Amer. Water Works Assoc.* 23(3): 435-444. Map. 1931.—Turbidity of the Detroit water supply is about 35 p. p. m., on the average. This low turbidity results in economy in the cleaning of settling basins, and yet is sufficient for aiding coagulation with alum. Increased turbidity serves as an indicator of pollution. Among plankton present in Detroit Water Supply are *Asterionella, Fragilaria, Anabaena, Synura* and hydra. The last is the only one that has ever given trouble in purification; it collects on filter walls in April and in November, necessitating scrubbing them off. Mineral content of only 96 p. p. m. in hardness and no Fe content saves the city thousands of dollars each year, because of the small amount of encrustation of boilers, hot water heaters, etc. —*B. Hudgins.*

16703. **JOHNSON, E. M. An attempt to control cyclops in a water plant.** *Jour. Amer. Water Works Assoc.* (*Proc. 50th year*) 23(4): 582-585. 1931.—The presence of *Cyclops* in the raw water of the Monroe, North Carolina, water supply reduced the length of filter runs from 26 hrs. to 13 hrs., other conditions being the same. $CuSO_4$ in large doses or prechlorination with doses as high as 0.8 p. p. m. failed to destroy *Cyclops*. Cl doses of 1.5 p. p. m. were somewhat effective. Larger doses could not be tried because of limitation of capacity of the chlorinator. Reference is made to the successful destruction of *Cyclops* by Frank Hale, New York City, with Cl doses of 1.0-3.0 p. p. m.—*C. R. Cox.*

16704. **LE-ROY y CASSÁ, JORGE. La primera epidemia de fiebre amarilla en la Habana, en 1649. [First epidemic of yellow fever in Havana, 1649.]** *Vida Nueva [Havana]* 25: 254-299; *Sanidad y Beneficencia [Havana]* 35(1/6): 64-109. Map; also publ. by "La Propagandista," 71p. Map. Havana, 1930.—Finlay affirmed the existence of this epidemic, based on a detailed study of the historians and, above all, on the Codices Mayas Chumayel and Tizimín, referred to by Bishop Dr. Carrillo y Ancona, by Cogolludo's description demonstrating the existence of yellow fever in Yucatán in 1648, and by Berenger Feraud's study citing the description by P. du Tertre, of the epidemic of this malady in 1648, in the Island of Guadalupe. A document, unknown until now, of the Captain General of the Island of Cuba, D. Diego de Villalba y Toledo, victim of yellow fever, demonstrates the introduction of "tabardillo" (the name for yellow fever in that epoch) by the fleet that came from Vera Cruz, Mexico. The author discusses the data reported by different authors. From a study of the records of deaths that occurred in Havana each day during the 17th century, he concludes that the epidemic took place during August and September, 1649; and demonstrates that this was the first invasion of yellow fever in Cuba. The disease known in epidemic outbreaks until the last introduction from Vera Cruz (1761) resulted in endemic establishment, until Gorgas eradicated it in 1901.—*J. Le-Roy y Cassá.*

16705. **LE-ROY y CASSÁ, JORGE. La mortandad en la Habana durante el siglo XVII. [Mortality in Havana in the 17th Century.]** *Vida Nueva [Havana]* 25: 414-435; *Sanidad y Beneficencia [Havana]* 35(1/6): 64-109. Map; also publ. by "La Propagandista," 71p. Map. Havana, 1930.—The author bases this study of mortality in the 17th century on the records in the parochial books, the only sources of information extant; in them he traces day by day and month by month the deaths registered in Havana, beginning with 1613, the date of the first of these records still existing. In this way he arrives at estimates of populations. He does not admit the supposed epidemic of yellow fever in 1620, which might have been malaria, smallpox or some other malady rather than yellow fever, which appeared in 1649. He discusses the other pestilences which might have affected the population, concluding with the epidemic of yellow fever and smallpox, well-attested, with which the century closed.—*J. Le-Roy y Cassá.*

16706. **LEVINE, MAX, J. H. TOULOUSE, and J. H. BUCHANAN. Effect of addition of salts on the germicidal efficiency of sodium hydroxide.** *Industr. & Engineer. Chem.* 20(2): 179-181. 1928.—Continuing studies on the germicidal properties of substances used in the mechanical washing of milk and other beverage bottles, experiments were carried out with the organism earlier employed (an unnamed bacillus resembling *B. subtilis, B. laterosporus* and *B. ruminatus*), isolated from ginger ale. Addition of NaCl, Na_2CO_3, or trisodium phosphate to NaOH markedly decreased the killing time at 50° and 60° C. The effects of equal weights of NaCl and Na_2CO_3 were approximately the same, whereas the phosphate was less efficient. As the concentration of salts added to the NaOH was increased the killing time decreased, but at a decreasing rate. It is suggested that the undissociated NaOH may be the agent which penetrates the cell. Addition of the various salts would increase the concentration of undissociated NaOH, or possibly decrease the solubility of the NaOH in the water phase which would tend to force the NaOH into the bac-

terial phase of the suspension. In either case the effect would be to increase the death rate of the bacteria.

16707. **MOHLMAN, F. W., T. L. HERRICK, and H. GLADYS SWOPE.** Technic of stream-pollution investigations. *Industr. and Engineer. Chem.* 23(2): 209-213. 1931.—Intensive studies of the condition of the Illinois River have been made by the Sanitary District of Chicago since 1925, although this work was begun in 1900. Sampling is a very important factor in stream surveys. The most representative sample was found by obtaining current meter readings and samples at various points across the stream and computing the weighted average. Depth of sample must be considered, since a deep sample may stir up sludge deposits in the river bed and, therefore, an abnormally high biochemical oxygen demand (B.O.D.) would be obtained. Sludge deposits, as long as they remain quiescent, cause no increase in O demand. Hourly samples are generally necessary in highly polluted streams or where large hourly variations in dissolved O occur. This was particularly true between Chillicothe and Peoria, due to photosynthesis. The 5-day B. O. D. was used daily, but studies were made weekly to determine the rate of B. O. D. from 1 to 40 days.—*F. W. Mohlman.*

16708. **LUCE-CLAUSEN, ETHEL M., and STANHOPE BAYNE-JONES.** The specificity of light action in experimental tuberculosis. *Amer. Rev. Tuberc.* 24 (6): 686-694. 1931.—Of 53 tuberculous guinea pigs, the average survival period was: for 17, receiving daily 15 min. ultraviolet exposure (317-430 m μ E 0.012 gm. cal/min./cm^2), 30 days; for 18, receiving daily 15 min. infra-red exposure (720-1120 m μ E 0.122 gm. cal/min./cm^2), 28 days; for 18 kept in a dark room, 33 days.

16709. **NAESLUND, CARL.** Experimentelle Untersuchungen über gewisse Faktoren, die für die Entstehung von Blausäurevergiftung bei Zyanwasserstoffbehandlung von Wohnungen und anderen Räumen von Bedeutung sind. *Upsala Läkareförен. Förhandl.* 34(5/6): 793-847. 1928/1929.—The author made numerous tests of ordinary building materials, foodstuffs, and of the various materials and substances which make up dwelling houses, etc., to determine what might be the factors involved in the cases of HCN poisoning following use of this gas as a vermifuge. He found that skins, down and similar articles held large quantities of this gas, and poisonous amounts were readily yielded after ordinary aeration or longer. For sanitary engineers the data here compiled will be invaluable.—*R. H. M'Gonigle.*

16710. **PARKER, R. R., ERIC HEARLE, and E. A. BRUCE.** The occurrence of tularaemia in British Columbia. *U. S. Publ. Health Repts.* 46(2): 45-46. 1931.—Recovery of *Bacterium tularense* from snowshoe rabbits (*Lepus americanus columbiensis*) and report of human cases, together with experimental evidence of transmission by ticks (*Haemaphysalis leporis-palustris*) from rabbit cases.

16711. **RIDLON, J. R.** Studies on Leptospira icterohemorrhagiae. *U. S. Publ. Health Repts.* 46(1): 1-5. 1931.—Leptospiras were found in the kidneys of wild rats from San Francisco Bay cities. These apparently conform to the descriptions of *L. icterohemorrhagiae.* Guinea pigs were inoculated with material from the kidneys of rats harboring Leptospiras and died, showing fever and jaundice of the eyes and skin before death. At autopsy they showed subcutaneous jaundice and hemorrhages of subcutaneous tissues and internal organs, which are the gross pathological changes described by several writers as typical of infection with *L. icterohemorrhagiae.* Leptospiras were found in the internal organs and urine of infected guinea pigs. Positive cultures were obtained. Guinea pigs were infected by injection of positive cultures. The disease was carried over in successive guinea-pig inoculations, both from original rat injections and from culture injections.—*Author's summary.*

16712. **SMITH, H. F.** Résumé of report on sanitation and yellow fever control in Liberia. *U. S. Publ. Health Repts.* 46(23): 1353-1359. 4 pl. 1931.

16713. **SOLLAI, GIUSEPPE, e CARLO G. CERRUTI.** Sull'epidemiologia dell'infezione melitense dell'uomo e degli animali in Sardegna, con particolare riguardo alla provincia di Cagliari. *La Nuova Vet.* 9(4): 137-144. 1931.—After mentioning the continual diffusion of *Alcaligenes melitensis* infection in man in Sardinia, the authors show that it is also prevalent and severe in the flocks of sheep and goats which by frequent elimination of the bacteria in the milk constitute a grave and permanent peril to man. They describe the course of the disease in these animals and indicate the best method of prophylaxis.—*C. G. Cerruti (transl. by L. W. Hackett).*

16714. **SYDENSTRICKER, EDGAR, and SELWYN D. COLLINS.** Age incidence of communicable diseases in a rural population. *U. S. Publ. Health Repts.* 46(3): 110-113. 1931.—This study, based on records of communicable diseases officially reported to the Cattaraugus County, New York, Health Department and supplemented by personal inquiries in a sample of the rural population consisting of approximately 5,000 persons, shows that the incidence of practically all the common infectious diseases is at later ages in rural than in urban populations for which similar data were available. The "lag" in age curves persists even when the rural population is classified according to farm and village. For most of these diseases,—particularly measles, whooping cough and diphtheria,—there is indicated a slower rate of immunization in more sparsely settled areas. On the other hand, in the instances of measles and whooping cough, it is shown that the % of persons at the age of 25 who had histories of attacks were about the same in both rural and urban areas.—*E. Sydenstricker.*

16715. **SYDENSTRICKER, EDGAR.** The incidence of influenza among persons of different economic status during the epidemic of 1918. *U. S. Publ. Health Repts.* 46 (4): 154-170. 1931.—In a survey of over 100,000 persons in 9 urban localities at the end of the influenza epidemic in 1918-1919, the families were graded according to economic status to ascertain whether or not the incidence varied in relation to this condition. Analysis of these records showed that the influenza and mortality rates were higher among persons living in poorer households than among those in well-to-do and moderate circumstances. The higher mortality rate was not due merely to higher incidence of the disease but also to higher fatality of the cases among poorer persons. This higher case fatality rate manifested itself particularly in the age groups 0-4, 15-34, and 45 yrs. and over, thus suggesting economic conditions in families with young children and with old persons. Household crowding, although a concomitant of poverty, did not appear to be the determining factor in this association of economic status and influenza.—*E. Sydenstricker.*

16718. **WEDEMANN, W.** Kann phosphorsaurer Futterkalk, der bei der Verarbeitung milzbrand-sporenhaltigen Knochenmaterials in Gelatinefabriken gewonnen wird, noch lebensfähige Milzbranderreger enthalten? *Arch. Wiss. u. Prakt. Tierheilk.* 63(3): 215-229. 1931.—Anthrax spores in bone material were destroyed in 2-8 hrs. in maceration fluid of 5.8-10.8° Baumé. The dicalcium phosphate obtained from similar maceration fluids and then dried at 50-70° C. for 72 hrs. is practically free from anthrax organisms. Maceration fluids of 10.4-15° Baumé do not kill anthrax spores in 15-72 hrs.; and the dicalcium phosphate obtained from such material was not free from living anthrax organisms even after drying at 50-70° for 72 hrs. These findings are applied to the method now commonly used for recovery of

dicalcium phosphate in connection wtih gelatin manufacture.—*H. C. H. Kernkampf.*

16719. **WILLIAMS, C. L. The fumigation of loaded ships.** *U. S. Publ. Health Repts.* 46(31): 1823-1836. 1931.—Fumigation of loaded ships is described as essentially a proper introduction of the gas by way of the ventilators, sounding pipes and other routes of access. Ways of utilizing these and special apparatus devised for these purposes are described. Cargo is divided into liquid, bulk, and package. The first is in itself rat destructive. Bulk and package cargo differ in that the former fills the holds to the ship's sides, while the latter is held away from the sides by battens; with either there is always space above the cargo. Gas spreads over the top of the cargo and, when this is package, down the sides and through the interstices. Rat harborages covered by cargo cannot be reached for the purpose of making openings for entrance of gas. Carefully carried out fumigations with HCN on loaded ships usually destroy 80% or more of the rats on board.—*C. L. Williams.*

16720. **WILSON, CHARLES C., IRA V. HISCOCK, J. H. WATKINS, and JARVIS D. CASE, with the cooperation of JOHN L. RICE. A study of illness among grade school children.** *U. S. Publ. Health Repts.* 46(31): 1801-1823. 1931.—Records of absences of 3 or more successive school days which occurred among pupils attending the New Haven, Conn., public schools during the school year 1927-1928 showed that 53.8% of all cases and 38.9% of the total days of sickness were due to respiratory illness. The specific communicable diseases of childhood caused 27.9% of the cases and 44.2% of the total number of days of sickness. The average number of days of sickness was greatest for the 5-yr. old group and decreased with age. The average number of days of sickness per case showed no consistent sex differences.—*C. C. Wilson.*

16721. **YANT, W. P., H. H. SCHRENK, F. A. PATTY, and C. P. WAITE. Acute response of guinea pigs to vapors of some new commercial organic compounds. VI. Dioxan.** *U. S. Publ. Health Repts.* 45(35): 2023-2032. 1930.—The toxicity of dioxan (1, 4-dioxan or diethylene dioxide) is comparatively low. The symptoms produced are eye and nasal irritation, with lung irritation after long exposure. High concentrations also cause narcosis. The chief pathological findings are edema and congestion of the lungs. Distinct warning by irritation of eyes and nose is produced in persons by concentrations of 0.16% or above. Considering the low toxicity and low vapor pressure of dioxan, as well as its warning properties, health hazards from breathing the vapors are remote under ordinary conditions of usage and reasonable exposure. As in the case of practically all comparatively non-toxic volatile liquids, however, dioxan presents a hazard to life under conditions of exposure to air confined over liquid in tanks, vats, and similar places where high concentrations would accumulate.—*W. P. Yant.*

16723. **BROWN, R. J., and H. W. DAHLBERG. Inversion of sucrose in beet-house sirups.** *Industr. and Engineer. Chem.* 21(3): 282-285. 1929.—A satisfactory method for determining invert sugar in beet-factory sirups is given. It is shown that the invert-sugar content of low-purity beet products can not be taken as a measure of previous inversion of sucrose, owing to the destruction of invert sugar; at pH 6-9 the rate of destruction depended on the concentration of impurities, the H- or OH-ion concentration showing no measurable effect. Decreasing the pH of the sirup from 8 to 6 increased the rate of loss of sucrose about 10 times. Decreasing the purity from 100 to 60% decreased the rate of loss of sucrose about 40%. A 10° C. rise increased the rate 2-3 times. Variations in concentration of solutions, in the range of 10-80% dry substance, produced no marked effect on rate. Rate of loss of sucrose in beet sirups from different sources was constant under constant conditions; in sirups of 90% purity at pH 6 and 80% dry substance heated at 80° C. it was almost double that calculated by Spengler and Tödt on the basis of the inversion constant of sucrose in HCl found by Jackson and Gillis.—*Courtesy Industr. and Engineer. 16724. **CHACE, E. M., and H. D. POORE. Quick-freezing citrus fruit juices and other fruit products. A preliminary report.** *Industr. and Engineer. Chem.* 23 (10): 1109-1112. 1931.—Experiments do not show that replacing the air in the head space above the juices or washing out dissolved air with CO_2 has any marked effect on flavor. Too much CO_2 gives an off-flavor. With frozen fruits, a slight improvement was noted when CO_2 was used; this was marked when friction-top cans were used. Vacuum-packed fruits are better than the ordinary pack. Freezing can readily be carried out in crown-capped glass bottles, 4- or 8-oz., before or after capping, and in 8-oz. glasses or 12-oz. glass jars, with or without vacuum. Open freezing and freezing in friction-top cans is not recommended unless special precautions are taken for storage out of contact with air.

16725. **CULPEPPER, C. W., and H. H. MOON. Sulphur-spray residues and the swelling of tin cans packed with peaches.** *Jour. Agric. Res.* 39(1): 31-40. 1929.—Sulphur-spray residues are sometimes rather difficult to remove from the surface of peaches; presence of this S in the can causes formation of H_2S and H gas, with consequent swelling of the can. Washing in cold or hot water is not always effective in removing spray material, but dipping the fruit in hot dilute lye solution followed by washing in jets of cold water is effective. Almost all forms of S in the acid juices of peaches cause swelling of the can, corrosion being caused by its combining with the metal and by its acting as a catalytic agent greatly accelerating action of the natural fruit juices on the metal. In absence of organic acids, no swelling occurs unless the S is in such form that it will combine with the metal, in which case it will corrode the can in absence of acids. H is formed by action of organic acids on the Fe, not the Sn; therefore gas formation should be less if the Fe were more completely covered with Sn. The electrochemical theory of corrosion seems to offer an adequate explanation of the phenomena observed: normal acid juices of peaches (containing oxidizing acids) act as electrolytes in which Fe is cathodic to Sn when they are in contact, but if a reducing agent such as H_2S is present this is reversed, the Fe becoming anodic and Sn cathodic. This relationship, together with the fact that H_2S accelerates the liberation of H from Fe, seems to account completely for swelling of the cans in the cases observed.—*M. W. Jennison.*

16726. **FLETCHER, LOUIS. Notes on the determination of dry matter (or moisture) in pressed yeast.** *Jour. Inst. Brewing* 37(10): 506-508. 1931.—5 gm. of unwashed yeast in a 50 mm. diam. dish is weighed, moistened with absolute alcohol and dried in a current of air for 7-9 hrs. in a water oven at 98°. A more exact method is to dry in a Lobry de Bruyn vacuum apparatus at 105°, the water being caught in H_2SO_4 bulbs. This method gives about 2¼% more water, but as the first method is easy to manipulate and gives uniform and reproducible re-

sults, it is recommended as a routine standard for relative results.—*L. Fletcher.*

16727. **HARLER, C. R. The firing of tea.** *Indian Tea Assoc. Sci. Dept. Quart. Jour.* 1930(2): 67-74. 1930.—This report deals with fermentation and drying of tea. During fermentation of the leaf, the principal chemical reaction is that of oxidation of the tannin with the aid of an enzyme in the leaf. Some tannin combines with protein in the leaf and becomes insoluble. During fermentation, there is steady loss in soluble solids. When firing begins, the rate of loss is greatly reduced. Firing inactivates the yeasts and other microorganisms on the leaf, but the fired tea gives a faint enzymic reaction resulting in a post-fermentation. This is believed to be responsible for the mellowing or maturing of tea. Optimum drying temp. vary with different conditions. Also, for teas from certain sections, i.e., northeastern India, double fire is adopted because of high moisture. In Ceylon, tea is usually fired in 1 process. Apparently, it is necessary to heat the leaf to 170° F. or more before the processes of fermentation are sufficiently slowed to allow the tea to be stored without losing quality. The author lists 5 points of most importance in firing tea in northeastern India.—*E. J. Cameron.*

16729. **TOULOUSE, J. H., with J. H. BUCHANAN, and MAX LEVINE. The action of citric acid and its salts in sugar solutions.** *Iowa State Coll. Jour. Sci.* 5(2): 89-120. 1931.—Addition of citric acid, to make 0.01-0.08 *M* acid solution, depending on the final acidity desired in a beverage, can inhibit or destroy yeast under certain conditions. The effect was more marked at higher sucrose concentrations (33-36° Bé.) and lacking in dilute syrups (24° Bé.). Increasing acid strength was highly effective, but it was shown that wide variation in rate of death of yeast occurred in certain solutions of the same pH. The presence of salts of citric acid lowered the germicidal effectiveness of the acid to a marked degree. A commercial process of "cold sterilization" of bottlers' syrups is indicated, since a 36° Bé. syrup, inoculated with yeast, containing 0.04 *M* citric acid, became sterile in 24 hrs.—*J. H. Toulouse.*

16730. **BONDIOLI, M. Quelques recherches sur la relation existant entre l'acidité d'un sérum-lactique et son contenu microbien.** *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(3): 77-78. 1931.—Coccus forms predominate in lactic whey as acid is first produced. As acidity rises, coccus forms are succeeded by bacilli, which produce more acid and are more acid-resistant. Samples of lactic whey obtained immediately after cheese making, were divided into 3 portions, held at different temp., and then tested separately for either total titrable acidity or pH value, and examined microscopically for bacteria. Results were plotted on curves (not presented) and the following conclusions drawn: At low temp., increase of acidity is directly proportional to time; at higher temp. the greatest increase occurs in the first 6 hrs. Ionic acidity increases most rapidly during the first 6 hrs. even at low temp. The proportion of coccus and bacillary forms was plotted against time; the time required for cocci and bacilli to reach equal numbers lessened as temp. increased.—*G. L. A. Ruehle.*

16731. **FABIAN, F. W., E. A. BEAVENS, C. S. BRYAN, and J. M. JENSEN. Influence of alkalies on available chlorine and on germicidal effect of sodium hypochlorite in presence of organic matter as ice-cream mix.** *Industr. and Engineer. Chem.* 23(10): 1169-1174. 1931.—In the absence of organic matter, such as ice-cream mix, NaOCl was stable for 1 hr. at 50° C., but in presence of organic matter, it rapidly lost its available Cl. NaOH and Na_2HPO_4 had a stabilizing influence on the NaOCl. Na_2CO_3 in small amounts stabilized the NaOCl but larger amounts tended to decompose it. With a decrease of organic matter, available Cl did not decrease quantitatively. Addition of alkalies to NaOCl in the presence of ice-cream mix increased the loss of available Cl and was proportional to the amount of alkali added. The influence of the alkalies in the order of their decreasing effect is: NaOH, Na_2CO_3 and Na_3PO_4. A large bacterial content reduced the available Cl. A comparison of the germicidal effect of NaOCl to which 0.5% of Na_2CO_3, NaOH and Na_3PO_4 have been added showed that, in presence of ice-cream mix: Na_2CO_3 was the least effective; there was a correlation between amount of available Cl present and the germicidal effect of the solution, especially true with Na_2CO_3; 0.5% NaOH and Na_3PO_4, when added to NaOCl, killed the bacteria in practically all cases; the effectiveness of NaOH was due to its pH, since experiments showed that it greatly reduced the loss of available Cl under similar conditions; adding 0.5% of Na_3PO_4 to the NaOCl solutions showed that it was as good as NaOH and better than Na_2CO_3 in killing bacteria.—*F. W. Fabian.*

16732. **HEIDUSCHA, ALFRED, und ERNST KOMM. Über das Vorkommen von Peptidasen in der Milch.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 196(3/4): 187-194. 1931.—High quality raw cow's milk usually gave negative tests for peptolytic enzymes with the glycyltryptophane reagent. Occasionally very slight hydrolysis of peptids was noted, ascribed to bacteria in the milk. Commercial raw milks with high bacterial counts usually gave marked hydrolysis of the dipeptids, also ascribed to bacteria. Results with high-quality pasteurized milks were variable. Enzymes were ascribed to bacterial contamination. Human milk gave no positive test; 3 samples of goats' milk were also negative. Fresh, sterile milk is thus considered free of peptolytic enzyme.—*From abstract by F. J. McClure.*

16733. **HUSSONG, R. V., and B. W. HAMMER. The isomeric forms of lactic acid produced in milk by some of the anaerobes.** *Iowa State Coll. Jour. Sci.* 5(3): 167-170. 1931.—A number of cultures of *Clostridium welchii*, grown in milk, produced lactic acid of the *d* type or a mixture of active and inactive acids; 2 cultures of *C. butyricum*, grown in milk, produced inactive lactic acid; others yielded, from 1300 cc. of milk incubated 1 week at 37° C., such small amounts of Zn salt of the non-volatile acid that satisfactory purification was impossible. *C. welchii* produced smaller quantities of volatile acid in milk than *C. butyricum.*—*Authors' summary.*

16734. **WALTON, J. H. Seasonal variations in the germ content of milk at Pusa.** *Agric. Res. Inst. Pusa Bull.* 170. 12p. 1927.—Plate and coli counts of milk varied seasonally, with highest counts in the rainy season, when the most scrupulous attention should be paid to cleanliness and to efficient sterilization of all utensils.—*Author's conclusion.*

(See also in this issue Entries 15353, 15467, 15534, 15571, 15604, 16772, 16951)

16735. **BAVENDAMM, WERNER.** The possible rôle of micro-organisms in the precipitation of calcium carbonate in tropical seas. *Science* 73(1900): 597-598. 1931. A preliminary report of bacteriological studies of the flora of mud collected from different locations and depths off the Great Bahama Banks, Andros Island and Williams Island, in connection with the International Expedition to the Bahamas, 1930. The opinion is expressed that micro-biological rather than chemical-physical processes are primarily responsible for $CaCO_3$ precipitation at these points.—*P. L. Gainey.*

16736. **BROWN, P. E.** Soil bacteriology as a science. *Proc. Iowa Acad. Sci.* 37: 59-64. 1930(1931).—Soil bacteriology is a distinct branch of science, related to bacteriology, botany, chemistry, geology and zoology, but especially to pedology. It utilizes methods and viewpoints from all these sources, but has developed a technique of its own, and has accumulated a body of knowledge. Its special importance is in relation to crop production.—*H. S. Conard.*

16737. **BURK, DEAN.** The influence of oxygen gas upon the organic catalysis of nitrogen fixation by Azotobacter. *Jour. Phys. Chem.* 34(6): 1195-1209. 3 fig. 1930.—The unique O pressure functions of *Azotobacter* with respect to respiration, growth, efficiency of growth, pH, and humic acid obtain in both free and fixed N. Hence, they offer no indication as to the nature of the chemical mechanism of N fixation. The mechanism of respiration has been interpreted in terms of both chain reaction kinetics and contact catalysis. With respect to the latter, the data presented are consistent with the view that both O and the organic molecule oxidized must be in contact with the solid respiratory enzyme catalyst for the reaction to take place measurably, bombardments of unadsorbed molecules being ineffective.—*Author's summary.*

16738. **MURRAY, A. N., and LEWIS CLINE.** Report of progress on the organic acids produced by the bacterial decomposition of plant material. *Proc. Oklahoma Acad. Sci.* 10: 95-96. 1930.—Experiments show that soil bacteria have the power of decomposing plant material with production of at least 2 fatty acids—butyric and propionic. The water in which the decomposition took place reached a maximum acidity of 0.10935 *N*.—*A. N. Murray.*

16739. **PENDLETON, RAY A., and FREDERICK B. SMITH.** Further studies on the nitrate assimilating power of soils. *Proc. Iowa Acad. Sci.* 37: 65-69. 1930(1931).—6 types of soil were tested, showing that accumulation of nitrate in soils depresses the vigor of the nitrate-assimilating organisms. Assimilation of nitrate is increased by addition of organic matter, in this case chopped straw.—*H. S. Conard.*

16740. **PORSILD, MORTEN P.** Giebt es Knöllchenbakterien auf Disko in Grönland? *Dansk. Bot. Arkiv.* 6(7): 1-7. 1930.—Contrary to a statement by Niels Nielsen, the occurrence of *Bacillus radicicola* is reported on Disko Island and other parts of Greenland devoid of wild Leguminosae, viz., in soils near the residences of Europeans. Also an abstract is given on the results of Swedish and English researches on the contents of bacteria and protozoa in Disko soils.—*M. P. Porsild.*

16741. **SMITH, FREDERICK B.** Effect of artificial manure on nitrification in Carrington loam. *Proc. Iowa Acad. Sci.* 37: 71-73. 1930(1931).—Presents results with artificial manures, farm manure, green manures and crop residues on nitrification. The first 2 stimulate nitrification. Straw and corn stalk residues increase nitrate assimilation and depress nitrification. Green manures increase both nitrate assimilation and nitrification, but nitrates accumulate in the soil.—*H. S. Conard.*

16742. **VERONA, O.** À propos de l'oxydation microorganique de l'acide salicylique. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(6): 218-220. 1931.—Salicylic acid, in suitable dilution, was used as a source of energy by certain soil microorganisms. With some soils the oxidation was rapid and complete and was distinctly influenced by the presence of disaccharids and of nitrogenous material.—*D. J. Healy.*

16743. **WALKER, R. H.** Studies on nitrogen fixation in some Iowa soils. *Proc. Iowa Acad. Sci.* 37: 75. 1930(1931).—Studies indicate that too little credit has been given to the anaerobic Clostridiums and too much to the aerobic Azotobacter group. Further study is needed.—*H. S. Conard.*

16744. **WAKSMAN, SELMAN A.** Chemical nature of soil organic matter, methods of analysis, and the rôle of microorganisms in its formation and decomposition. *Compt. Rend. Deux. Comm. Assoc. Internat. Sci. Sol [Budapest]* A 1929: 172-197. 1929.—At a high annual temp. and in well aerated soils, very little organic matter or none will accumulate in the decomposition of plant and animal residues, due to the fact that the soil microorganisms can decompose organic matter more rapidly than the plant residues can supply it. At a low annual temp. and in water-logged soils, organic matter accumulates. In the decomposition of plant residues in the soil, the water-soluble substances are the first to be acted on; then the proteins, certain hemicelluloses, and celluloses. The lignins are more resistant to decomposition in aerated soil and are practically undecomposed in water-logged soils. The soil organic matter is made up of a number of chemical complexes, depending on the nature of the plant and animal residues, on the microorganisms active in decomposition of those residues, and on the environmental conditions, especially moisture, temp., aeration and reaction, at which decomposition is taking place. The only reliable method at present available for determination of total soil organic matter is the C content of the soil as measured by wet or dry combustion. The earlier assumption that the soil organic matter contains about 58% C is confirmed by more recent investigations. As a result of the decomposition in the soil of plant residues of a wide C:N ratio, considerable quantities of CO_2 are liberated and only limited amounts of NH_3 or nitrate, until a soil organic matter has been produced of a fairly constant C:N ratio. Further decomposition leads to a parallel liberation of both C and N, in the form of CO_2 and NH_3, the latter being rapidly changed, in normal soils, to nitrate. Either liberation of CO_2 or formation of nitrate can be used with equal justification as index of decomposition of soil organic matter.—*S. A. Waksman.*

16745. **WILSON, J. K.** Nodule production on etiolated vetch seedlings. *Phytopath.* 21(11): 1083-1085. 1 fig. 1931.—Vetch seedlings were grown on sterile synthetic agar to which various saccharids were added; into the agar, 2 days after seeding, active culture of *Rhizobium leguminosarum* was inoculated and the whole continually kept from sunlight. After 36 days, plants grown on sugarless medium showed only 1 nodule in about 40 plants; with levulose, but 1 was found. Plants grown with saccharose developed nodules in all concentrations tried, more being present at 0.5 and 1% than at 2%. With other sugars, varying results, according to sugar, were obtained. Infection by *Rhizobium* may occur before photosynthesis has begun and, if suitable conditions are maintained by supplying a satisfactory carbohydrate, macroscopic nodules may develop in absence of light.—*W. A. Whitney.*

GENERAL BACTERIOLOGY

R. E. BUCHANAN, *Editor*

(See also in this issue Entries 15159, 15408, 15409, 15569, 15582, 15616, 15625, 15658, 15774, 16447, 16487, 16547, 16591, 16658, 16673, 16674, 16676, 16677, 16682, 16733, 16737, 16738, 16742, 17593)

16746. **ANDERSON, R. J. A discussion of certain fat constituents of acid-fast bacteria.** *Amer. Rev. Tuberc.* 24(6): 746-750. 1931.—Chemical analyses of human, avian and bovine type tubercle bacilli, timothy bacillus and leprosy bacillus shows that all acid-fast bacteria contain, in greatly varying proportions, similar lipoids belonging to the 3 general groups: phosphatides, acetone-soluble fat, and wax. Human type tubercle bacillus yields 10 times the amount of phosphatide contained in the non-pathogenic timothy bacillus, which, in view of the cell-stimulating, antigenic and other properties of the phosphatides, suggests that pathogenicity may bear some relation to phosphatide content. The timothy bacillus contains an acid which, though optically inactive, gives biologic reactions similar to those of the dextro-rotatory phthioic acid isolated from human type tubercle bacillus. Hence, the possibility that timothy bacillus may acquire virulence should, the author believes, be reinvestigated.

16747. **BARELLI, L. Influences de liquides organiques sur le développement cultural du bacille tuberculaire.** *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(9): 532-538. 1931.—Mixture of a synthetic non-protein medium with fresh serum for several days inhibits growth of tubercle bacilli, probably through bacteriolytic activity; later, growth is accelerated, probably because complementary action remains inactivated in the thermostat and the nutritive function of the serum constituents dominates. Mixture with reheated serum for ½ hr. at 56° always considerably accelerates growth. Mixture with washed erythrocytes has a somewhat tardy favorable action. Mixture with leucocytes from sterile exudate of guinea pigs gives initial inhibitory, followed by a certain favorable, action; the latter dominates if the leucocytes are freed of exudate by washing. At first there probably is a certain bacteriostatic action of the exudate serum accompanying the normal antibacterial thermolabile powers (complementary function). However, when this action is eliminated by holding in the thermostat or by washing of the leucocytes, the cellular constituents of blood or exudate are shown to contain a growth-promoting principle or to furnish nutritive substances. With this method no traces of antibacterial principles are evident. Hemoglobin dissolved in the medium has a rather favorable action on growth. Non-protein ultrafiltrate from acetic collodion filters has a rather inhibitory action, perhaps by dilution of the medium; if there is any antibacterial action here, it is uncertain and hardly probable, but the bacilli grow with considerable difficulty in pure ultrafiltrates.—*Author's conclusions (transl.)*.

16748. **BETTENCOURT, NICOLAU de. Étude sur les types "S" et "R" de l'Éberthella typhi.** *Arq. Inst. Bact. Camara Pestana* 6(2): XI-XXVI. 1 pl. 1930.—The author evoked microbic dissociation in an old strain of *Eberthella typhi* by successive culturing in phenol broth. Studying the cytomorphosis, growth curve and resistance to physical and chemical agents, he failed to observe appreciable differences between "S" and "R" types. The latter are not to be considered as a degenerative or involution form. Changing the proportion of phenol and incubation time of the "S" type cultures caused the "passage" S > R to appear suddenly, with the characteristics of a mutation-like phenomenon. The experiments to provoke the reversion R > S by changing the reaction (pH 6.0 to 8.2) and the nature of the culture media were unsuccessful; only successive and direct passages in the pleural cavity of guinea pigs produced once on 3 series the reversion R > S. Study of the antigenic constitution agreed with nearly all other work on the serology of "S" and "R" forms. In 1 of 17 cases of enteric fever, the patient's serum, examined on the 6th and the 10th days of illness, was negative with formolized broth cultures (Dreyer) and positive (1:100 and 1:400) with the alcoholized suspension (medium of Bien) of the "S" form—small-flake agglutination.—*N. de Bettencourt*.

16749. **BOISSEVAIN, C. H., and C. T. RYDER. Some observations on chemical and biological properties of the phosphatide from the tubercle bacillus.** *Amer. Rev. Tuberc.* 24(6): 751-756. 1931.—Intraperitoneal injection of a phosphatide, prepared according to Anderson's directions for phosphatide A3, causes formation of tubercular tissue and appearance of cutaneous hypersensitiveness in guinea pigs. It is impossible to free this phosphatide from acid-fast bacilli and bacillary debris by centrifugation, precipitation, or filtration of its ethereal solution. Filter candles that retain bacilli suspended in water let the same bacilli pass through when suspended in ether. It is possible to free the phosphatide from bacteria and bacterial debris by dialysis of the ethereal solution through a rubber membrane, subsequent solution in a mixture of water, alcohol and ether, and filtration through a Mandler filter candle. Intraperitoneal injection of the purified phosphatide does not cause formation of tubercular tissue or appearance of cutaneous hypersensitiveness. The tissue reaction to phthioic acid is of the nature of a foreign-body reaction.—*Authors' summary*.

16750. **CERRUTI, CARLO G., et G. SOLLAI. Étude bactériologique de cinq souches de Br. melitensis de provenance ovine et caprine, isolées en Sardaigne. Classification de deux de ces souches dans le groupe paramelitensis.** *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(3): 69-72. 1931.—Isolation in Sardinia of 5 strains of *Brucella*, 2 of which (Arbus and Serbariu) were of caprine and 3 (Dolianova I and II and Gonnesa) of sheep origin. Besides the 2 goat strains which are not agglutinable with abortus and melitensis sera, all 5 strains showed the morphological, cultural, biological, and biochemical characteristics of *Brucella*. Moreover, the 2 goat strains inoculated into a rabbit had a very weak antigenic power. Several strains of abortus-melitensis used for cross tests were found to be non-sensitive, or nearly so, to the agglutination of the same sera, as had been demonstrated by Nègre and Raynaud. On the basis of other reactions (thermo-agglutination, non-specific agglutination), the authors classify the caprine strains under paramelitensis and the sheep strains under melitensis.—*C. G. Cerruti (transl. by P. Hillkowitz)*.

16751. **COLLEY, MARY WOTHERSPOON. Stimulation phenomena in the growth of bacteria as determined by nephelometry.** *Amer. Jour. Bot.* 18(4): 266-287. 1931. —When a relatively heavy inoculum of *Escherichia coli* was introduced into broth containing 0.0001 *N* $ZnSO_4$, more gas was produced than in control cultures. *E. coli* colonies grown in 0.001 *N*, 0.002 *N*, 0.003 *N*, and 0.004 *N* $ZnSO_4$ agar were initially larger than controls. After 8 hrs. incubation, size difference was most pronounced. The contrast was less marked at 12 and 16 hrs. and after 20 and 24 the once large colonies became approximately the same size as controls. Greatest growth as shown by colony area was 58% in 0.003 *N* $ZnSO_4$ after 8 hrs. *E. coli* colonies grown in weaker concentrations of $ZnSO_4$, 0.0001 *N* and 0.00025 *N*, were initially inhibited, but after 16 and 20 hrs. they increased so that after 24 hrs. they were 9% larger than controls. Colonies containing more than 0.005 *N* $ZnSO_4$ showed no stimulation, but an increasing toxic effect. *Serratia marcescens* colonies grown in 0.002 *N*, 0.003 *N*, 0.004 *N*, and 0.005 *N* $ZnSO_4$ agar were initially larger than controls. This difference was most marked in early growth stages. Greatest increase was 72% with 0.004 *N* after 16 hrs. A relative decrease

in size followed, which in the case of those which had been most stimulated approached within 6-8% of the normal after 48 hrs. *Azotobacter chroococcum* cultures grown in a mannitol solution containing dilute solutions of $ZnSO_4$ showed by their turbidity, measured nephelometrically, a growth increase in the presence of 0.000005 *N* and 0.000007 *N* $ZnSO_4$. This was greatest (17%) after 5 days with the 0.000007 *N*. With stronger concentrations, 0.000009-0.002 *N*, growth was initially inhibited. No growth occurred in presence of 0.005 *N*. Similar cultures containing manganese sulphate showed increased growth with 0.00001 *N*, 0.00005 *N*, 0.0001 *N*, and 0.0005 *N* after 2 days. This increase, greatest with the 0.00005 *N* after 2 days, was not maintained, and after 15 days, the cultures appeared subnormal. No growth occurred in presence of 0.01 *N* manganese sulphate. Other test salts were too toxic in dilutions used to give data on growth stimulation. Their toxicity may be judged by the highest concentrations in which no growth occurred: $Co(NO_3)_2$ 0.0001 *N*, $CuSO_4$ 0.0001 *N*, $Ni(NO_3)_2$ 0.00005 *N*, and $Cd(NO_3)_2$ 0.00005 *N*. Presence of metallic test salts in the *A. chroococcum* cultures seemed to bring about abnormally early pigmentation of cells and to shorten the life of the culture. *Pseudomonas tumefaciens* grown in a synthetic medium at 22 and 28° C. was shown by turbidity measurements to be stimulated at both temp. by presence of 0.00005 *N* $ZnSO_4$. Degree of stimulation, however, was greatest at 28°, maximum being 20% after 7 days. With increase in available O no growth stimulation was produced by $ZnSO_4$. This was also the case when dextrose was increased. Cultures of *P. tumefaciens* grown at 28° showed maximum growth increase of 28% after 5 days in presence of 0.0005 *N* manganese sulphate. As with $ZnSO_4$, when O tension was increased, there was no growth stimulation produced by manganese sulphate. *P. tumefaciens* grown at 28° with dilute solutions of $Co(NO_3)_2$ showed maximum growth increase of 19% after 5 days in presence of 0.00001 *N* dilution of the salt; and with $CuSO_4$, maximum growth increase of 52% after 5 days with a 0.00005 *N* dilution of salt.—*Author's summary.*

16752. **CORTESE, FRANZ. Esame fluoroscopico di alcuni actinomiceti. [Fluoroscopic investigation of certain Actinomyces.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 842-844. 1930.—The author had previously reported the occurrence of a reddish fluorescence in certain strains of *A. bovis* under Wood's light. He now reports that these strains are facultative anaerobes and that the fluorescence appears only when the cultures are exposed to O. There is no fluoroscopic difference between strains grown in light and in darkness; direct sunshine is destructive to these strains. Strains grown on strongly acid or alkaline meat broth were more fluorescent than those on neutral media. Since the fluorescence occurred only in cultures on meat broth media, the attempt was made to grow the strains on "peptoglucosate" agar to which small amounts were added of constituents of the meat broth or substances chemically akin to these. Addition of phytin or "inotsal" elicited fluorescence; addition of creatine or inosite did not. The fact that the fluorescence-inciting substances are esters of phosphoric acid, comparable in chemical structure to the hexosephosphoric esters of muscle, suggests that the fluorescence may be connected with the presence in the culture medium of phosphorated compounds. The fluorescent substance, extracted with ether, was an amorphous brownish-red porphyrin; the spectroscopic and other characters of its solutions are described. Fluoroscopic studies show that under the name of *A. bovis* Harz different species are ordinarily described, especially *A. albus* and *A. sulphureus* Gasperini.—*M. Comel.*

16753. **DIMITRIJEVIÉ-SPETH, VOJIN. Weitere Erfahrungen mit Agargelatine und ihre verschiedene Durchlässigkeit für Bakterien. [Further experiments with agar gel and variations in its permeability to bacteria.]** *Zentralbl. Bakt. I. Abt. Orig.* 112(1/2): 17-25. 1929.

16754. **EVANS, ALICE C. A new subspecies, radicans, of Alcaligenes faecalis.** *U. S. Publ. Health Repts.* 46 (29): 1676-1680. 1931.—*A. faecalis* ssp. **radicans** (p. 1676) from the blood of a patient with a mild case of a fever resembling typhoid. Cultural and biochemical reactions are discussed. The patient's serum gave no agglutination with typhoid or paratyphoid A and B antigens. Intraperitoneal and intrapleural inoculations of 2 guinea pigs led to a mild peritonitis, congestion of the omentum, and an abscess near the stomach in 1 case, the organism being recovered from the abscess. In 2 rabbits and 2 mice, no pathogenicity was observed; on a few weeks' cultivation the organism apparently lost its mild pathogenicity for guinea pigs.

16755. **FOURMENT, PIERRE. Contribution à l'étude des boues végétominérales (barègines) contenues dans les eaux sulfurées-sodiques de Barèges (Hautes-Pyrénées).** *Bull. Soc. Hist. Nat. Afrique du Nord* 21(2): 11-24. 1 pl., 5 fig. 1930.—The sodic sulphated waters of Barèges favor the growth of micro-organisms, sulphuraria, adapted to this particular medium by reason of thermality and S content. In this vegeto-mineral spring baregin (or glairin) is formed at the expense of sulphuraria (*Thiothrix*), constituting an organic and mineral complex. The bulk of it originates from destruction of the dead cells of sulphuraria. This disorganization first affects the mucilaginous sheath, passing to the cellular membrane and finally destroying the protoplasm. By a combination of biologic and physical causes, there is an accumulation of mineral principles in baregin. There is 1st a protoplasmic appearance of granules of S in a soft state which, by destruction of the sulphuraria, take on rapidly a crystalline form; 2nd, a fixation by adsorption of various mineral principles, among which are silicates and salts of Fe, the latter passing through successive stages of reduction and oxidation. Baregin is a characteristic of water formed at thermal stations in southern France, e.g., Barèges and Aix-les-Bains. The author notes that the richness of these mucilaginous bodies in mineral elements explains the use of these soft masses as an aid in hydromineral cures; but he warns that it might be dangerous to apply them to mucous surfaces, or to the cutaneous surface if it has been injured or has lost its integrity, because of a possible septic character. The S is in a soft state but not colloidal. Illustrations show the filament of *Thiothrix,* the cells of which contain S; and filaments with empty vacuoles and protoplasmic granulations. Others show the filament of *Thiothrix* after plasmolysis and the attachment of the growth of *Thiothrix* and the floating masses.—*G. Hinsdale.*

16756. **GOLDIE, HORATIO. Studien über die Anäeroben-Umwandlungen.** *Zentralbl. Bakt. I. Abt. Orig.* 117 (6): 384-395. 1930.—The bacilli of Shiga and of Flexner, *B. typhosus,* and *Vibrio cholerae* underwent permanent changes in cultural characteristics when small amounts of sterile pus were added to their young bouillon cultures. Similar studies were made of the effects of leucocytes on anaerobes. Sterile pus from guinea pig abdomens was added to cultures of *B. botulinus* and *B. tetani.* This transformed the bacilli, enabling them to grow aerobically through many transplants; only the young bacilli were changed. Probable reactions of enzymes from leucocytes on the bacilli are discussed.—*W. N. Berg.*

16757. **HILL, FR. Zur Biologie des Paratyphus B-Bazillus. (Verhalten in Glyzerin-Fuchsinbouillon, Rhamnoselösung und Ammoniumchlorid-Rhamnoselösung.)** *Zentralbl. Bakt. I. Abt. Orig.* 113(5/6): 348-352. 1929. —Paratyphoid B bacilli, Schottmüller type, are recognizable by their ability to ferment glycerol and by the change of color in Stern's glycerol-fuchsinbouillon. Most Schottmüller bacilli ferment glycerol in 72-96 hrs. at 37°C. The degree of color produced varied from light to dark red. Tests with 90 strains in rhamnose solution of Bitter, Weigman and Habs, and in ammonium-rhamnose solution of Pesch and Masche, showed agreement 65 times. 25 strains gave negative results in rhamnose solution; in the ammonium-rhamnose solution only 12 of the 25 gave negative results. Thus, the ammonium-

rhamnose solution seems superior to rhamnose solution. 7 Breslau strains fermented glycerol in 48 hrs. In the Bitter, Weigman and Habs bouillon, and also in that of Pesch and Masche, they showed corresponding red color. —*H. J. Stafseth.*

16758. **KAPLAN-BRILLE, ALICE. Influence du nombre des microbes ensemencés sur la mutiplication du bacille pyocyanique dans un milieu de culture liquide.** 110p. Imprimeries Vieillemard: Paris, 1931.—4 chapters are devoted to techniques used for quantitative study of bacterial growth; to growth phases in cultures; and to results of studies on the influence of numbers of bacteria seeded on the multiplication of *Bacillus pyocyaneus* in culture media. The numbers of bacteria were determined by microscopic count, and by plating in agar. The number of cells found by direct count is always larger than from plating. The ratio between plate count and microscopic count, called "vitality ratio," is not a constant. It varies from one experiment to another in spite of efforts to maintain constant environmental conditions. It varies during the growth of the culture. It is at a minimum during the first hrs. after seeding, then increases, and may exceptionally assume a value of nearly unity, but generally does not rise above 0.4-0.5. Maximum value is found toward the close of the logarithmic growth period, then it decreases. Microscopic counts reveal no latency period following seeding; the logarithmic period of increase follows immediately. Enumeration by plate counts shows a latency period. During the logarithmic growth phase, the generation time is apparently shorter for bacteria, determined by plating. The total "crop yield" is of the same order of magnitude irrespective of size of initial seeding (250 thousand to 500 million seeded). Total numbers by microscopic count varied from 14 to 23 thousand millions, and by the plate count from 2.5 to 9 thousand millions. Duration of logarithmic growth period is relatively constant, except with very large seedings. The morphology of the bacterial cells undergoes regular variations, which follow quite regularly the growth phases. The maximum cell length, which is 2-3 times that of the cells seeded, is attained at the end of the logarithmic growth period, usually about 10 hrs. after inoculation. A bibliography of 112 titles is included.—*R. E. Buchanan.*

16759. **KITAOKA, MASAMI. Über ein neues Phänomen bei Wasserleptospirenkultur. Eine Methode zur Reinkultur der Wasserleptospiren mittels dieses Phänomens.** *Proc. Imp. Acad.* [*Tokyo*] 7(2): 82-83. 1931.—In the isolation of water Leptospiras from impure cultures, cultures made on Ringer's agar sometimes contain, 2-3 cm. deep, pure, ring-shaped colonies of *Leptospira,* contaminating organisms being superficial. To enable the bacteriologist to fish out such colonies, a special culture vessel was devised, having a closed side arm in which such deep colonies may develop. With pathogenic *Leptospira* spp., isolation is more difficult.

16760. **KOPACZEWSKI, W. Conditions physico-chimiques de la vitalité microbienne.** *Arch. Mikrobiol.* [*Berlin*] 2(2): 187-244. 12 fig. 1931.—A critical discussion of the chemical composition of media; biological factors influencing growth, such as antagonism and synergism of microbes; and physical factors, such as radiations, pH, electrical conductivity, electric charge, and surface tension. The physical modifications (density, surface tension, viscosity and reaction) of different culture media (broth, serum and tomato juice) produced by 20 species of bacteria, including pathogenic and saprophytic forms, are detailed. Physical modifications which the organisms produce in the course of their growth depend on the initial chemical composition of the medium; particularly on the pH. The sp. is also a determining factor. Definite periodicity may be noted. Physical changes are most marked in media with low buffer capacity. Bacterial antagonisms may be largely explained by the physical variations produced. The senescence of cultures is accompanied by physico-chemical modifications such that the medium becomes unsuited to growth. If the medium is restored to its initial condition, growth again occurs. The therapeutic effect of old microbial cultures may be explicable on the basis of physico-chemical action rather than of "specific antagonistic virus." Resemblances between changes produced by the microorganisms in media and in the humors and tissues of the body are emphasized as suggestive of a more direct and simple explanation of pathogenic changes.—*R. E. Buchanan.*

16761. **LOELE, W. Über die Verwendbarkeit von Oxydationsreaktionen mit Paraphenylendiamin in der Bakteriologie.** *Zentralbl. Bakt. I. Abt. Orig.* 111(6/8): 325-335. 1 fig. 1929.—The author compares the paraphenylendiamine oxidation reaction with the indolphenol blue reaction in yeasts and in a large number of bacteria of various types; results were similar in both tests. He notes special points in connection with individual bacteria and discusses the importance of the oxidation reaction of bacteria, from various points of view. Among his conclusions he states that bacteria may be divided into 4 groups according to behavior in a solution of paraphenylendiamine.—*M. L. Orcutt.*

16762. **LOGHEM, J. J. van. Zur Terminologie der bakteriellen Veränderlichkeit.** *Zentralbl. Bakt. I. Abt. Orig.* 120(5/6): 318-320. 1931.—The author points out that inheritance of acquired functions, flexibility of the genotypical constitution, instability of species, transgression of the limits of the species and "Dauermodification" are conceptions not accepted in the genetics of the higher organisms but which nevertheless have found a place in microbiology. In his own attempts at classifying the phenomena of bacterial variability he has arrived at a physiological conception: if not the single bacterial cell but the clone (i.e., the posterity of a single cell) is taken as the individual (individual line, individuality), the variations to be observed in the clone are recognized as functional phenomena within the inidividual existence of the bacterium. Accordingly, he proposes to distinguish bacterial variability as adaptation (physiological reaction on the influences of the outer world), and regression (pathological reaction); and the bacterial variations as adaptate (adaptatively changed), mutilate (permanently mutilated), atropheont (a function irretrievably lost), and degenerant (permanent change, manifesting itself as a phylogenetic regression or atavism). —*J. J. van Loghem.*

16763. **MARCHOUX, E., et V. CHORINE. Culture des spirochètes de la poule.** *Compt. Rend. Soc. Biol.* 106(12): 1125-1128. 1931.—The best medium consisted of slants of coagulated egg white or coagulum in physiological saline covered by a solution of serum diluted with physiological saline and containing 0.2% peptone and 0.1% glycogen. Optimum temp. was 37°C.; optimum pH, 7.5-7.7. The first cultures succeed only in rabbit serum, but after the 4th or 5th subculture, horse, ox, or human serum may be used. A cover of vaseline oil 1 cm. deep is also necessary.—*E. Weiner.*

16764. **MATERNOWSKA, IRENA. Eine biochemische Methode zur feineren Differenzierung der Bakterienarten der Coli-Typhusgruppe auf dem eiweissfreien Pesch-Maschke-Nährboden.** *Zentralbl. Bakt. I. Abt. Orig.* 113 (5/6): 361-365. 1929.—Determining the pH changes in liquid media of Pesch and Maschke (NH_4Cl and rhamnose) during 3 weeks after inoculation and noting turbidity of the broth, provided a satisfactory method of differentiating Breslau and Gärtner strains of *Bact. enteritidis, Salmonella schottmülleri,* and *S. suipestifer.* The Gärtner strains (16), all serologically similar, could be divided into 2 groups by this method. *S. suipestifer* would seem to belong between the Breslau and Schottmüller organisms.—*Leona Baumgartner.*

16765. **MICKLE, FRIEND LEE. Brief notes on laboratory incubator temperatures.** *Ann. Rept. Internat. Assoc. Dairy & Milk Inspect.* 19: 288-300. 1930.—A study of the effect of various loadings and environments of bacteriological incubators on temp., with recommendations as to studies needed.

16766. **MORELLI, E. Observations à propos du polymorphisme des streptothrichées.** *Soc. Internaz. Micro-*

biol. Boll. Sez. Ital. 2(6): 299-304. 1930.—*Nocardia, Cohnistreptothrix* and actinobacilli isolated from actinomycotic foci are described. The author believes them all to be different phases of the same variable organism. On artificial media and after long cultivation he was able to make these, and some old stock, cultures go through all the forms which have been given as characteristic of the different species. All gradations between the 2 forms were observed, which ruled out the possibility of having started with a mixed culture. Methods of cultivation which brought about these changes, as described, consisted of changing the organisms from anaërobic to aërobic growth, or vice versa, and addition of substances, like blood, to the media. The author believes that *Streptothrix* is a basic form with great polymorphic power, by which it can adapt itself to parasitic life in the group of mycobacteria, corynebacteria and the other forms of *Cohnistreptothrix* and actinobacilli.—*M. S. Ingalls.*

16767. **POTTENGER, JOSEPH E. The demonstration of rare tubercle bacilli in sputum by the dilution-flotation method in conjunction with picric acid.** *Amer. Rev. Tubere.* 24(5): 583-595. 1931.—Picric acid as a counterstain in preparations of rare tubercle bacilli yields over 5 times the number obtained by methylene-blue. The latter, in the concentration usually employed, should be discarded for this purpose. The dilution-flotation method, followed by picric acid as a counterstain, gives an average of over 60 times as many bacilli as can be found in direct smears from most likely particles, counterstained with methylene-blue, and 150-250 times as many in homogenized materials. The method detects as few as 1,000 bacilli in many 24-hr. sputa, thus limiting materially the use of the more time-consuming methods of culture and guinea pig inoculation. Perfect acid-fast rods were found in many specimens wholly negative by the Ziehl-Nielsen method. Failure to find bacilli may not always be due, as generally believed, to the presence of other pleomorphic forms, to the exclusion of acid-fast rods.—*Author's summary.*

16768. **REED, GUILFORD B., and CHRISTINE E. RICE. The behaviour of acid-fast bacteria in oil and water systems.** *Jour. Bacteriol.* 22(4): 239-247. 1931.—The work of Mudd on the behavior of acid-fast bacteria in oil and water systems was confirmed, using a macroscopic, in place of his microscopic, method. On shaking watery suspensions of acid-fast bacteria with oil they readily pass into the oil, while non-acid-fast organisms remain in the water. The same reaction occurs with a variety of fat solvents. The partition is complete for tubercle bacilli and 70-90% for 6 other acid-fast spp. Homologous immune serum inhibits the partition in proportion to its concentration. Emulsifying agents have a similar effect.—*G. B. Reed.*

16769. **RIGOBELLO, G. A propos de l'antagonisme entre le B. pyocyanique et son filtrat vis-à-vis de différents bactères "in vitro" et "in vivo."** *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 2(6): 332-336. 1930.—A comparison between the effects of the filtrate of a culture of *Bacillus pyocyaneus* and of pyocyanase in vitro and in vivo. One can prepare strains of anthrax bacillus attenuated for rabbits by previous treatment with filtrate of *B. pyocyaneus.*—*R. Dubos.*

16770. **RYTI, ELSA. Studien über Bakterien der Coligruppe.** *Acta Soc. Med. Fennicae "Duodecim"* [*Suomalaisen Lääkäriseuran Duodecim'in.*] 13[Ser. A.] (3): 1-54. [Art. 6] 1931.—Of 320 bacterial strains isolated from various habitats (blood, gastric and duodenal contents, urine, feces), all were Gram-negative, motile, and failed to liquefy gelatine; they belong thus to the coli-group in the broadest sense. 5 of the strains were Voges-Proskauer-positive, 3 being methyl-red-negative and belonging thus to the aerogenes group (American system). Of the Voges-Proskauer-positive strains, 2 were invariably methyl-red-positive, thus forming a kind of intermediate form between aerogenes and coli bacilli. Of the Voges-Proskauer-negative strains, 6 fermented none of the sugars or polyvalent alcohols examined (glucose, lactose, mannite, maltose, salicin, saccharose); and, moreover, produced no indol; they thus belong to Petruschky's faecalis alkaligenes bacteria. Further, 5 strains were lactose-negative, but fermented all the monosaccharide sugars and produced indol; some of them, moreover, fermented certain other sugars, belonging thus to the so-called Morgan's bacilli. 304 of the strains belong to the true coli bacilli, and may, on account of their relation to fermentation of the sugars examined, production of indol, and causing of hemolysis in blood-agar, be divided into 14 groups. The greater the number of characteristics taken into consideration and the greater the number of bacterial strains examined, the more numerous are the groups found as based on biological characteristics; no uniform classification of the coli bacilli is thus obtained. Agglutination tests, using immune serum from 30 different rabbits, produced with 24 different strains, showed that some strains produce almost strain-specific sera, while other sera agglutinate a greater or lesser number of foreign strains, this condition being, however, completely irregular and quite independent of the biological characteristics and origin of the bacteria. Sera produced by aerogenes and Morgan bacilli are capable of agglutinating the true coli bacilli; it thus seems almost impossible to classify coli bacilli on their manner of agglutination.—*Author's summary.*

16771. **SCUDDER, SARA ALICIA. A differential stain favorable to the diagnosis of neisserian infection.** *Stain Technol.* 6(3): 99-105. 1 col. pl. 1931.—A differential Gram stain incorporating combined features of original Gram and Pappenheim methods. National Aniline crystal violet and new methyl green and pyronin are preferred. Iodine mixture of Kopeloff and Beerman is a satisfactory mordant, and Merck's pure technical acetone is an excellent differentiating agent. Gram-positive bacteria are coated by buffered crystal-violet solution, and iodine-NaOH solution precipitates crystal violet from other substances. The dye-iodine precipitate dissolves readily in pure acetone. Iodine green, a pure derivative of crystal violet, has the effect of non-interference in the technic and has selective action on nuclear substance. Pyronin has affinity for neisserian organisms primarily and acts as inert substance on most other proteins (except cytoplasm of eosinophiles, lymphocytes, plasma cells, and endothelial cells). Technic recommended: Stain air-dry films 3-5 min. in 1% solution of crystal violet in 10 parts Clark and Lubs' phosphate buffer of pH 6.6-7.0 and 90 parts water. Decant and flush with 2% iodine in *N*/10 NaOH. Decant and decolorize in acetone 10 sec. or less. Air dry and counterstain 1½-2 min. with methyl-green-pyronin (2 parts 2% aqueous methyl green National with 1 part 0.3% aqueous pyronin yellowish). Wash and air dry. Oil of bergamot is preferable to xylene as clearing agent.—*Author (courtesy Wistar Bibl. Serv.).*

16772. **SMIT, JAN. Die Gärungssarcinen. Eine Monographie.** 59p. 6 pl., 10 fig. Gustav Fischer. Jena, 1930. Price 9 M.—The author reviews the literature on *Sarcina ventriculi, S. maxima, S. paludosa,* and the methane sarcinae; and describes isolation of sarcinae from gastric contents, various soils, atmosphere, grains and sewage, and the morphology and physiology of the group. He creates the genus **ZYMOSARCINA** (Coccaceae) (p. 26) to include *Z.* **ventriculi** (*Sarcina ventriculi* Goodsir) (p. 27); *Z.* **maxima** (*Sarcina maxima* Lindner) (p. 27); and *Z.* **methanica** (p. 27) for the methane sarcina first studied by Söhngen but not obtained in pure culture, and which is probably identical with *Sarcina paludosa* Schröter. *Z. ventriculi* and *Z. maxima* are found to be very acid-tolerant, growing at pH 0.8-9.8. These sarcinae are strict anaerobes, under ordinary conditions forming no colonies on petri plates. Fermentation of glucose by *Z. ventriculi* yields CO_2 and ethyl alcohol, with small amounts of acetic, lactic, formic and succinic acids and of H. *Z. maxima,* on the other hand, yields CO_2, H and acetic, butyric and lactic acids as the chief products, only small amounts of ethyl alcohol being produced. Presence in the soil of resistant, long-lived and perhaps invisible forms is shown.—*M. Johnson.*

16773. **SUGIMOTO. Untersuchungen über die Bedeutung akzessorischer Nährstoffe für den Verwendungsstoffwechsel der Typhus-Coli-Gruppe.** *Arch. Hyg. u. Bakteriol.* 106(4): 185-196. 1931.—2 strains each of *Bacillus coli, B. paratyphi, B. hominis,* Breslau bacillus from meat, *B. pestifer, B. typhi,* Kruse-Shiga and Flexner bacilli, *B. paratyphi A,* and *B. pyocyaneus* were grown on 8 media, the control and base being 0.5% NaCl and 0.2% K-biphosphate in double distilled water made to pH 7 with KOH, using as source of N: ammonium lactate, tartrate, oxalate, sulphate plus Na_2CO_3, chloride plus glycerine, chloride plus dextrose, and chloride. Thereafter, lemon juice 1:1000 as source of vitamine C and ether extract of lemon rind as source of vitamine A, 0.2% alcohol, or 0.008% Na-citrate plus 0.001% fructose were added to each of the media. Both the vitamine additions and the chemical control solutions (Na-citrate and alcohol) resulted in acceleration of growth, growth on inadequate media, increased glycerine decomposition, and stimulation to color formation (with exception of *B. paratyphi A* in all instances, and Shiga in most). Thus, the accessory growth substances exerted no specific stimulus, chemicals producing the same effect.

16774. **TANAKA, KUNIO. Studies on the effect of metals and metal salts on microorganisms.** *Jour. Biochem. Tokyo* 13: 81-105. 1931.—Chlorides of Au, Cu, Ni, Co, Fe and Zn, and $AgNO_3$ were used on *Bacillus typhosus, Bacterium coli commune* and *Staphylococcus pyogenes aureus.* In the lower concentrations, bactericidal action became greater with increase in concentration up to a certain point, fell off with further increase, and finally became greater again with very high concentrations. This is explained by the fact that addition of increasing quantities of a chloride increases the acidity, finally making it more acid than pH 4.5, which is the isoelectric point for bacterial proteins. Metal-ions can combine with proteins only on the alkaline side of this point; hence, bactericidal effect lessens with increasing concentration of chloride on the acid side of the isoelectric point. Employment of $CuCl_2$ in experiments in which the acidity of the solution was kept more alkaline than pH 4.5, showed progressively greater bactericidal effect with increase in concentration. The Gram-positive *Staph. pyogenes* is more resistant on the acid side and less resistant on the alkaline side of the isoelectric point than are the Gram-negative *B. coli* and *B. typhosus.*—*J. S. Caldwell.*

16775. **TYCHOWSKI, ALEXANDER, und MARIA KOBEL. Über eine schnell verlaufende Umwandlung von Hexose-di-phosphat in Lactat unter dem Einfluss des typischen Milchsäurebildners Bacillus delbrücki. [Rapid breaking up of hexose diphosphate into lactate, as affected by the typical acid-producing Bacillus delbrücki.]** *Biochem. Zeitschr.* 209(1/3): 134-141. 1929.

16776. **UBERTINI, BRUNO. Caraterri culturali, biochimici e sierologici del "Gruppo Intermedio" (Standfuss) paragonati a quelli dei germi del gruppo Paratifo B avvelenatori da carne. Appendice: Alcuni reperti di Paratifo B negli uccelli. [Cultural, biochemic and serological characteristics of the "intermediate group" (Standfuss) compared to those of the Paratyphoid B group of meat poisoning. Appendix: some findings in paratyphoid B in birds.]** *Clinica Vet.* 54(2): 80-107. 1931.—"Intermediate group" organisms are frequently found both in the deeper layers and on the surface of organs of animals killed or dying as a result of disease, and even in healthy animals. The biochemical and serological behavior of this group, though similar to that of the paratyphoid (as regards action on glucose, lactose and mannitol), nevertheless permits a sufficiently exact and rapid individualization. Differentiation from paratyphoid B is necessary in the practical bacteriological examination of meats because in the present state of knowledge the "intermediate group" is not to be considered pathogenic for man. Consumption of meat in which "intermediate group" bacteria have been found, produces no disturbance in human health. In the present state of our knowledge, the meat poisoning bacteria of the paratyphoid B group are the following types: Gärtner, Breslau, Schottmüller, suipestifer. In the Province of Brescia it was possible to isolate an enzoötic of the paratyphoid B Breslau type in canaries and another of the same type in pigeons of a military pigeon house. Bacteriological examination of a turkey cock after death showed the presence of paratyphoid B, Gärtner type. In a young turkey from a flock in which there was an epidemic of infectious entero-hepatitis, there was found a bacillus with morphologic, biochemic and serologic characteristics of paratyphoid B, Breslau type.—*B. Ubertini (transl. by P. Hillkowitz).*

16777. **WERKMAN, C. H. Dimethyl-alpha-naphthylamine for the determination of bacterial reduction of nitrates.** *Proc. Iowa Acad. Sci.* 37: 53-55. 1930(1931).—1 cc. is dissolved in 5 cc. of methyl alcohol and the volume made up to 100 cc. with 5*N* acetic acid. It is used with sulphanilic acid solution: 0.8 gm. in 100 cc. of 5*N* acetic acid. 1 cc. of each solution is added to approximately 5 cc. of the culture to be tested. The pink color develops within 3 min., and holds well. It is sensitive to $1:10^7$ dilution of the NO_2-ion.—*H. S. Conard.*

16778. **WREDE, FRITZ, und E. STRACK. Über das Pyocyanin, den blauen Farbstoff des Bacillus pyocyaneus. III. Die Konstitution des Hemipyocyanins.** *Hoppe-Seyler's Zeitschr. Physiol. Chem.* 177(3/4): 177-186. 1928.—Pyocyanin is deep blue. It has the empirical formula $C_{26}H_{24}N_4O_2$. The pure pigment is basic. Its salts are wine red. Although it is extraordinarily resistant to acids it can be split by prolonged hydrolysis. About 80% of the initial wt. is recovered after hydrolysis. One of the split products is hemipyocyanin (empirical formula $C_{13}H_{12}N_2O$). The author thinks that pyocyanin is composed of 2 molecules of hemipyocyanin. The latter behaves as an acid of about the strength of phenol. It dissolves in acids to give a wine red, and in bases to give a violet red, solution. On neutralization it is precipitated as yellow crystals. Pure hemipyocyanin was found by the author to be identical with hydroxyphenazine (structural formula given). It has a melting point of 158° C. [uncorrected]. The calculated molecular wt. was 196; the wt. found, 204.—*N. M. Payne.*

16786. MARÉCHAL, P. Études sur les rubicoles 2: Rhopalum clavipes L. et R. tibiale F. [Studies on bramble insects.] *Ann. Soc. Ent. France.* 98: 111-122. 2 pl. 1929.—Describes nest-making habits, metamorphosis, larvae, pupae and cocoons. An account of mixed nests is given. The following parasites are reported: *Caenocryptus macilentus* Grav., *Melittobia acasta* Smith, *Ptychoneura melaleuca* Meig and *Megaselia rata* Wood?. —*P. Maréchal (transl. by A. C. Hodson).*

16787. MASSEE, A. M. The control of the fruit tree red spider (Oligonychus ulmi C. L. Koch) of plum during the growing season. *Jour. Pomol. and Hort. Sci.* 8 (2): 184-194. 1 pl. 1930.—In England this serious pest of plums occurs commonly in orchards sprayed during the dormant season with a tar-distillate winter wash. It is essential to continue using the tar-distillate washes though the red spider is not controlled by them, as other important pests and diseases such as plum aphids, winter moth and brown rot are controlled by tar-distillate spraying. The fruit tree red spider can be controlled by spraying, about 2 weeks after the blossoms have fallen, with lime-sulphur 1-99. The spray does not reduce the crop, or cause any form of injury to the foliage or fruits. White oil emulsion (1%) and Bordeaux mixture (8:12:100) are not toxic to the mites.—*Author's summary.*

16788. MASSEE, A. M. The tarsonemid mite of strawberry. *Jour. Pomol. and Hort. Sci.* 8(4): 305-308. 1 pl. 1930.—Healthy Royal Sovereign strawberry plants became diseased and malformed when attacked by *Tarsonemus fragariae* Zimm. The older leaves became crinkled and very brittle. The young leaves turned a silvery-brown color, and remained stunted or dried up. Attacked runners were also malformed, and produced unhealthy plants. All the "control" (non-infected) plants remained healthy.—*Author's summary.*

16789. MILES, HERBERT W. Tar-distillates for the winter spraying of apples in North-West England. *Jour. Ministry Agric. [Gr. Brit.]* 36(2): 145-152. 1929.—Five brands of tar-distillate washes and dinitroorthocresol were tested against aphids, apple sucker, apple capsids, tortrix larvae and larvae of the winter moth and its allies. Yield and percentage of clean fruit were increased and appearance of foliage improved in the sprayed plats. All brands of tar-distillates were about equally effective, giving a considerable but not perfect control of aphids, apple sucker, winter and tortrix moths. Capsids were not controlled. Dinitroorthocresol was equally effective; slightly less so against winter moths.—*H. Baker.*

16790. MILLER, N. C. E. Coccus (Lecanium) viridis Green. The "Green scale" of coffee. *Dept. Agric., Straits Settlements and Fed. Malay States, Sci. Ser.* 7. p. 17-29. 5 fig. 1931.—*Coccus (Lecanium) viridis** is a serious pest of coffee wherever grown. In Malaya it occurs also on *Bassia latifolia, Achras sapota,* and *Citrus acida.* It is usually attended by the ant, *Oecophylla smaragdina,* which consumes the sticky juices exuded before

the sooty mold can spread over the leaves and kill the scales. The species is parasitized in Malaya by *Aneristus ceroplastae**, *Coccophagus* sp. [Eulophidae], and *Encyrtus flavus** [Encyrtidae], and is also attacked by the fungus *Fusarium*, probably *F. aleyrodis*. Spraying with kerosene emulsion is effective; other sprays are also used with good results, as tobacco-soap solution, resin-soda, and lime-sulphur. Control of *O. smaragdina* is also necessary, and consists of destruction of the nests on the tree and banding of trunks with tanglefoot.

16791. MORRIS, H. M. A survey of olive pests. *Dept. Agric. Cyprus (Ent. Ser.), Bull.* 2. 1-10. 4 fig. 1930.—The principal olive pests in Cyprus are the olive fly, *Dacus oleae;* the olive moth, *Prays oleellus;* the olive weevil, *Rhynchitis ruber;* a cecidomyid larva; and the scale, *Leucodiaspis riccae*, all of which cause the olives to fall. The type of injury to fruit, for the first 4 spp., is illustrated.

16792. PAGDEN, H. T. Two citrus fruit borers. *Dept. Agric., Straits Settlements and Fed. Malay States, Sci. Ser.* 7. p. 1-16. 9 fig. 1931.—*Prays endocarpa** [Lepidoptera, Hyponomeutidae] attacks *Citrus medica acida, C. limonum, C. decumana,* and *C. aurantium;* it breeds in the fruit, forming surface galls, but leaves the fruit to pupate. The egg*, larva*, pupa* and adult* are briefly described. The larvae are parasitized by *Euderus malayensis** [Chalcidoidea, Eulophidae]. No practical control measures so far tried are really successful except the destruction of injured fruit. *Citripestis sagittiferella* also feeds on the same fruits as *Prays endocarpa*, but its damage is much more severe. Where several larvae attack a single fruit, the entire contents are destroyed. The adult* is described by H. M. PENDLEBURY. The egg*, larva*, and pupa* are described. The larva is parasitized by a Tachinid and a Braconid, near *Chelonus*. As control measures the writer does not favor lead arsenate although effective, because of its effect on the flavor of the fruit, but recommends the use of tuba [Derris] or some other vegetable poison containing rotenone. Collection and destruction of damaged fruit is advised. The females are attracted to oil of limes, and will oviposit on paper painted with it. The principal ingredient of oil of limes is citral.

16793. PETTEY, F. W., and C. J. JOUBERT. Pear mealy bugs and results of experiments for their control. *Union So. Africa Sci. Bull.* 95. 1-23. 5 fig. 1930.—Two mealy bugs occur—*Pseudococcus maritimus* and *P. gahani*. The former is the more common and abundant. The life cycle and habits of both are similar. About 2½ months are required for the life cycle in summer and five mo. in winter. The eggs are laid in waxy ovisacs in crevices, under loose bark, under codling moth bands, and in calyx cavities. Damage arises chiefly from the staining of the fruit by the sooty fungus which grows on the honeydew. Some varieties of pears are preferred by the bugs to others. Infestation is heavier on late varieties and in the hotter and drier localities. Spraying should always be preceded by scraping the rough bark off the trunks and branches in winter and removing, so far as possible, all egg masses with a brush. Hessian should first be spread on the ground to catch the fallen bugs and eggs. Control by spraying is difficult and costly and in the heaviest infested areas it is questionable whether it would not be more economical to wipe the fruit. No spray gave appreciable results except an oil spray. Only 1 application of the usual winter oil spray can be given without injury to the trees if the oil in this ranges from 50 to 70% unsulphonatable residue and has a viscosity of about 110 seconds Saybolt. The strength of each spray in actual oil must not exceed 4%. No single winter application will give control of the infestation if at all heavy because no one application will kill all eggs. Possibly oils lighter in viscosity and of fairly low refinement might permit of 2 winter applications at 7% strength, 6-8 weeks apart, and effect control. In fairly light infestations and in comparatively cool areas, a winter application of 4% oil plus the substitution of 5 applications of a 1% medium grade summer oil and 40% nicotine sulphate 1-1600 for the 5 last arsenate of lead sprays, gave promising results.—*L. Caesar.*

16794. YGLESIAS, BERNARDO R. Costa Rica: The "enfermedad del café." *Internat. Bull. Plant Protect.* [*Rome*] 5(9): 158-159. 1931.—Due to serious attack, principally of young plants, by 3 insects: *Saissetia hemisphaerica, Pseudococcus* sp., and an aphid.

16798. HARDY, F., and G. RODRIGUEZ. Froghopper investigation. Progress report, June 18, 1930. *Proc. Agric. Soc. Trinidad and Tobago* 30(7): 260-266. 1930.—Notes on froghopper incidence, and attempt to cope with the outbreak by use of cyanogas and natural control.

16799. HOLDAWAY, F. G. The pink bollworm situation in Australia. *Trans. 4th Internat. Congress Ent., Ithaca, New York, 1928.* 2: 73-80. 2 fig. 1929.—The reasons for the present confusion regarding the pink bollworm situation in Australia are discussed. There occur in Australia not only the true pink bollworm, *Pectinophora gossypiella* Saund., but also 3 other spp., one of which is the Queensland pink bollworm, *P. scutigera* Holdaway. A brief discussion of the generic synonymy is given and the opinion expressed that *Pectinophora*, not *Platyedra*, is the correct genus for the pink bollworms. The original home and the world distribution of *Pectinophora* are discussed in the light of Wegener's hypothesis of the origin of continents. If this hypothesis is in principle correct then the apparently anomalous situation of the genus *Pectinophora*, and more particularly *P. gossypiella*, indigenous to Africa, Asia and Australia, is explained.—*F. G. Holdaway.*

16800. HOYER, C. Der "nebelige Schildkäfer." Ein wenig bekannter, jetzt häufig auftretender Rübenschädling! [The helmet beetle, a little known but frequently encountered beet pest.] *Deutsche Landwirtsch. Presse* 57(35): 477. 1930.—Note on *Cessida nebulesce* L.

16801. MILLER, DAVID. Insects infesting Phormium. *New Zealand Jour. Sci. and Tech.* 11(5): 273-283. 5 fig. 1930.—Two spp. of *Phormium* grow in New Zealand. *P. tenax* is milled for its "flax" fibre, and is cultivated mainly in the swamp areas. On the mountains it occurs in native stand along with *P. cookianum*. The insect fauna are all endemic. The most important enemies are those attacking the leaf, principal among which is the looping grub, *Orthoclydon praefectata*, which attacks both spp. The moths are nocturnal, depositing their eggs in batches, with a total fecundity average of 200 eggs. The larvae* feed on the epidermis and are nocturnal,

hiding during the day in dead leaf tubes. Flooding is fatal to the larvae and pupae, pupation taking place in the comparatively dry ground. The sp. is 2-brooded with a main generation and an overlapping generation as shown by a graph. The drainage of the swamplands for more extensive cultivation of the flax has been favorable to greater damage by this insect. Next in importance is the notching-grub, *Melanchra steropastis*, which cuts triangular notches in the leaves. To maintain control it is necessary to keep the soil comparatively moist, as the damage is greatest in dry lands. These 2 spp. are attacked by the parasites *Ichneumon* sp., *Paniscus productus* and *Phorocera marginata*, and by *Syrphus ropalus*, whose larvae feed on the young caterpillars. The case moth, *Oecticus omnivorus*, is of minor importance. The leaves are also attacked by *Leucaspis cordylindis*, *L. stricta*, *Trionymus diminutus*, and *Coelostomidia cordylindis*; the crown and leaf bases are attacked by larvae of *Porina signata*. A moth and a chloropid fly breed in the seeds. In the gummy fluid at the base of the plant are found larvae of *Lepidomyia decessum*. The larvae of *Batrachedra arenosella* feed upon the scale insects *Leucaspis cordylindis* and *L. stricta*.

16802. **PAGDEN, H. T. A preliminary account of three rice stem borers.** *Dept. Agric., Straits Settlements and Fed. Malay States, Sci. Ser. No.* 1. 1-30. 1 col. pl., 7 fig. 1930.—*Diatraea auricilia** oviposits in masses, the flat overlapping eggs* being found on rice leaves. The larvae* bore in the stems; they also attack *Scirpus grossus* and *Zea mays*. The eggs are parasitized by *Trichogramma nanum**, ? *Paranagrus optabilis*, and ? *Phanurus beneficiens*; the larvae, by *Apanteles flavipes*; and the pupae*, by a chalcidoid insect. *Schoenobius incertellus** deposits its eggs* in masses covered with anal hairs of the adult. The larvae* bore downward in the stalk of rice; no alternative host was found. They pupate in a silken cocoon. The eggs are parasitized by *T. nanum* and *P. beneficiens*. *Sesamia inferens** deposits loosely adhering strings of depressed spherical eggs*; the larvae* bore in the stalks of rice, maize, sugar cane, and *Paspalum commersonii*, and can also breed in *Eleusine indica*. No egg parasite has been found under natural conditions, but *T. nanum* will attack in the laboratory. The larvae are attacked by *Winthemia semiberbis*, and the pupae* by the same chalcidoids as *D. auricilia*, and by a *Xanthopimpla*. The ant *Diacamma vagans* (?) was observed extracting *Sesamia* larvae from rice stems. The life history of *T. nanum* is discussed, with descriptions of egg*, larva*, and pupa, and data on the experiments in mass breeding, using eggs of *Sitotroga cerealella*.

16803. **PHILLIPS, W. J., and G. W. BARBER. A study of hibernation of the corn earworm [Heliothis obsoleta Fab.] in Virginia.** *Virginia Agric. Exp. Sta. Tech. Bull.* 40. 1-24. 10 fig. 1929.—In studies in central Virginia covering 8 yrs., the kind of food apparently had an influence on the tendency of individuals to hibernate even as early as midsummer. Larvae that enter the ground from the 1st to the 3rd week in September usually hibernated most successfully, provided they had the proper food. Larvae construct emergence burrows for the escape of the adults and the pupae rest in a cell at the bottom of the burrows. The depth of the pupal cell ranges from ½ inch to 9 in. The fall burrows are much deeper than those in summer. The percentage of larvae that failed to pupate after entering burrows ranged from 41.8 to 43.7. Mortality of pupae was greatest from November to January. Emergence may occur from the last of May until August. Moles are the most important predaceous enemy of hibernating pupae.—*W. J. Phillips.*

16804. **RADEMACHER, BERNHARD. Der augenblickliche Stand der Rübenaaskäferbekämpfung.** *Zuckerrübenbau* 12 (5) : 84-89. 3 fig. 1930.—On control of *Blitophaga opaca* L., *B. undata* Müll. and *Silpha obscura* L. on beet.

16805. **ROOKE, H. G. D., with introduction by J. F. WEBSTER. Note on locusts in 'Iraq and the control measures adopted.** *'Iraq Dept. Agric. Mem.* 13. 1-13. 5 pl., 1 map. 1930.—A record of the results of studies by the Locust Department in 'Iraq since its inception in October, 1924, describing the organisation of the locust campaign, the life history of the Moroccan Locust, *Dociostaurus marocanus* (the species most destructive in 'Iraq), and the movements of these locusts within the country. Damage to crops and the natural enemies and other control factors are dealt with also. The most successful control methods have been ploughing of infested areas, spreading of poison bait, and spraying during the earlier stages of the hopping locusts.

Wood Preservers' Assoc.* 26: 318-337. 3 fig. 1930.—A progress report of test pieces of western yellow pine treated with various preservatives and set in Panama Canal Zone, Australia, South Africa and Hawaii.—*W. H. Snell.*

16808. **HUNT, G. M., and T. E. SNYDER. An international termite exposure test. Second progress report.** *Proc. Amer. Wood Preservers' Assoc.* 27: 279-285. 2 fig. 1931.—In some cases, the test sticks reported upon in 1930 have been removed to locations where termite attack would be more certain or more severe. Some of the preservatives have proven very effective after 1-2 yrs., but it is too early to arrive at definite conclusions as to specific toxic agents at this stage. Preservatives have not shown equal effectiveness at all 4 stations, perhaps because of the presence of different spp. of termites.—*W. H. Snell.*

16809. **KING, H. H. Experiments with arsenite of soda and sulphate of copper for the protection of timber against attack by termites.** *Wellcome Trop. Res. Lab., Ent. Sect. Bull.* 31. 22-32. 1 pl. 1930.—A report on the superficial treatment of logs of *Pinus* sp., *Hyphaena thebaica*, and *Acacia arabica*, with arsenite of soda and copper sulphate, soaking for 24 and 48 hrs., and treating ½ of each lot with tar to hold in the poison. Copper sulphate will not protect wood from attack of termites over a period of yrs. Arsenite of soda affords a high degree of protection.

16810. **KOFOID, C. A. Why is there a termite problem in California?** *Proc. Amer. Wood Preservers' Assoc.* 26: 298-306. 1930.—A complete discussion of the biological and ecological relations of California species of termites, with special reference to changes in the economy of nature brought about by the use of wood by civilized man.—*W. H. Snell.*

16811. **PASSERINI, N., e R. PAMPANINI. La conservazione degli erbari e l'efficacia del sublimato ($HgCl_2$) nell'avvelenamento delle piante. [Conservation of her-**

baria and the efficacy of $HgCl_2$ in poisoning plants.] *Boll. R. Ist. Sup. Agrar. Pisa* 3: 411-453. 1927.—Various chemicals are considered. CS_2 is recommended for general purposes and Na-arsenite for protecting the specimens against insect attacks.

16812. PÉREZ, DELFÍN GONZÁLEZ. Como prevenir el "Apolillado" de las frutas secas. [How to prevent moth injury to dried fruits.] *Bol. Min. Agric. Chile* 3(1/3): 84-88. 1931.—The best prevention is to expose the fruit as short a time as possible after it is dried. For fumigation in stores CS_2 is recommended.

16813. RANDALL, MERLE. Termites and the retail distribution of treated timber products. *Proc. Amer. Wood Preservers' Assoc.* 26: 207-214. 1930.

16814. SPENCER, G. J. An important breeding place of clothes moths in homes. *Canadian Ent.* 63(9): 199-200. 1931.—The principal household pests in British Columbia are the webbing clothes moth, *Tineola biselliella*, and the case-making clothes moth, *Tinea pelionella*. All stages of these moths were found during the winter in the felt accumulating from sweepings in the cold-air shafts of hot-air furnaces.

16815. WILLE, JOHANNES. Lasioderma serricorne F. als Schädling an Baumwollsamen. [L. serricorne as a pest of cotton seed.] *Anzeiger Schädlingsk.* 7(10): 110-112. 1931.

16816. WILLIAMS, C. L. Effect of fumigation on cockroaches on ships. *U. S. Publ. Health Repts.* 46(29): 1680-1694. 1931.—In laboratory tests it was found that with exposures of 2 hrs. (standard exposure period for quarantine fumigations with HCN), a maintained concentration of 1 oz. per 1000 cubic feet was required to kill all free running forms of *Blatella germanica* and twice this dosage to kill the eggs. When adequate harborage was provided, 4 oz. per 1000 cubic feet was necessary to kill the eggs. Concentration tests on ships demonstrated that only ½ the calculated concentration could be counted on as actually present. Therefore, on ships a dosage of 8 oz. per 1000 cubic feet was indicated as necessary; a further safety margin of 2 oz. is suggested. Practical tests on ships confirmed these laboratory figures. Since the cockroach is not believed to carry quarantinable diseases, its destruction by fumigation on ships should for economic reasons be restricted to the crew's quarters.—*C. L. Williams.*

16818. BARNES, H. F. Further results of an investigation into the resistance of basket willows to button gall formation. *Ann. Appl. Biol.* 18(1): 75-82. 2 pl. 1931. —Twelve commercial varieties of *Salix triandra*, under experimental conditions, were very susceptible to attack by the button top midge (*Rhabdophaga heterobia*). Three varieties of *S. purpurea*, 1 of *S. viminalis*, 3 hybrids of *S. viminalis* and *purpurea* and *S. alba* var. *vitellina* were totally immune. Notwithstanding eggs sometimes being laid and the larvae hatching, no galls or side-branching occurred. From field observations a closely allied gall midge, *R. terminalis*, is known to attack *S. alba* var. *vitellina*, but has not been known to attack any variety of *S. triandra*. Reference has been made to a similar phenomenon with regard to attacks on willows by the Chrysomelid beetles *Galerucella lineola* (apparently confined to varieties of *S. triandra*) and *Phyllodecta vitellinae*, which is known to attack *S. alba* var. *vitellina* and *S. purpurea* and its varieties but no variety of *S. triandra*. Hybridization of *S. triandra* × *S. purpurea* or × *S. viminalis* or × *S. alba* should be attempted. Mention is made of 3 aspects of host plant preference needing special attention in connection with willow gall midges.—*Author's summary.*

16819. BEDFORD, H. W. A preliminary note on die-back of sunt (Acacia arabica Willd.). *Wellcome Trop. Res. Lab., Ent. Sect. Bull.* 31. 39-41. 1930.—The die-back disease manifested by exudations of gum is primarily due to buprestid larvae, principally *Anthaxia congregata*, which is parasitized by *Hecabalodes anthaxia;* although *Chrysobothris dorsata* has been bred from diseased timber. Branches which have died from die-back are subject to the attack of *Sinoxylon senegalense* and *S. sudanicum*. The gum is sometimes dark colored, possibly due to the presence of bacteria, which however are not regarded as true parasites.

16820. BELL, C. F. Administration of the Forest Department of the Central Provinces for the year ending 31st March 1930. p. 1-35. 1931.—The epiphytotic sal borer (*Hoplocerambyx spinicornis*) attack has been successfully overcome by burning infested trees and by trap tree operations combined with beetle catching operations, at a cost of Rs. 1,25,801 during the last 4 yrs. The severe attack of the borer *Coelosterna scabrata* Fabr. in plantations of *Acacia arabica* is ascribed to planting the *Acacia* pure in dry and unsuitable localities. Over 95% of the trees are attacked in such localities.—*M. V. Laurie.*

16821. BERTHET, H. Sur la présence de Cossus terebra (Fabr.) dans les Alpes françaises et particulièrement en Oisans. *Bull. Soc. Ent. France* 1931(5): 76-78. 1931.—The larva of *C. tenebra* feeds on *Populus tremula* and *Betula alba* in the French Alps.—*S. B. Fracker.*

16823. CHAMBERS, E. L., and N. F. THOMPSON. Some of the more important insects and plant diseases of Wisconsin trees and shrubs. *Wisconsin Dept. Agric. and Markets Bull.* 123. 1-58. 57 fig. 1931.

16824. FRYDRYCHEWICZ, JULJUSZ. Żerowanie gąsienic Brudnicy nieparki (L. dispar L.) w świetle cyfr i pewne dane z jej biologji. [Voracity of Lymantria dispar larvae.] [With French summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest. Ann.)* 19(2): 171-186. 2 fig. 1928.—Laboratory experiments showed that a larva of *L. dispar* which moults 5 times devours in the course of its life 27 oak leaves of average size, while one which moults 4 times eats about 16 leaves. The chrysalis period in the ♂ averages 17.3 days, that of the ♀ 14.4 days. 19% of the ♂ leave the chrysalis after 15 days and 34.1% of the ♀ at the end of 14 days. A newly formed ♀ chrysalis weighed 890 mgm. (av. of 67), while that of a ♂ (av. of 76) weighs 420 mgm. The ♀ imago weighs 430 mgm. (48% of the newly formed chrysalid) while the ♂ imago weighs 85 mgm. (20% of the chrysalid).—*From author's summary (transl.).*

16825. GRAHAM, SAMUEL A. The larch sawfly and forestry. *Trans. Internat. Congress Ent., Ithaca, N. Y., 1928* 2: 401-407. 1929.—This paper discusses the im-

portance of the larch sawfly, *Lygeonematus erichsoni* Hartig, in the swamp forests of the northern States and summarizes some results of experiments in the Lake States, especially the effects of physical and biotic environmental factors. Excessive heat and moisture are important factors in preventing successful hibernation of the sawfly. Mice are important enemies of the sawfly in the cocooned stages and destroy on the average more than 50% of the cocooned prepupae. The larval numbers are reduced by heavy rains during the first instar and by parasites and predatory spp. during the 4th and 5th instars. It is clear that the physical conditions existent in tamarack (*Larix laricina*) swamps are favorable to the sawfly. Unless it is possible either to modify these conditions or to increase biotic resistance by favoring the enemies of the sawfly, the future of tamarack as a timber tree is dubious. It is believed that means of accomplishing the desired results will ultimately be found.—*S. A. Graham.*

16826. **MALENOTTI, ETTORE.** Osservazioni sui rapporti fra Diaspis pentagona Targ. e Prospaltella berlesei How. [Relations between D. pentagona and P. berlesei.] *Atti Accad. Agric. Sci. e Lett. Verona Ser. 5* 9: 97-106; also in *Italia Agric.* 68(5): 289-293. 1931.—Although *P. berlesei* is a specific endoparasite of *D. pentagona*, it does little harm to the latter along roads traversed by speedy traffic, because the dust drives away the parasites. After these roads are paved, the ravages of *Prospaltella* immediately increase. In a trip of 250 km. through the Apennines, on all the mulberry trees infested with *D. pentagona*, *P. berlesei* was also found abundantly. No effort has been made to disseminate this endoparasite artificially, since it is probably diffused throughout Italy.—*E. Malenotti* (*transl. by P. Popenoe*).

16827. **MARCU, O.** Contribuţiuni la oecologia unor distrugători ai pădurilor Bucovinei. [Ecology of some forest insect pests of Bukowina.] [With German summary.] *Intâiul Congr. Nat. Naturalişt. România* 1: 327-336. 3 fig. 1928(1930).—Biological associations in bark beetles as described by Borce for *Ips typographus* and *Pityogenes chalcographus* are not the only ones in this family. Every conifer has various associations varying with the age and health of the tree. In sound trees such associations are found mostly at the top but descend as the top becomes damaged. In young fir, associations occur between *Cryphalus abietis* and *Pityogenes chalcographus* and between these and *Pityophthorus micrographus*. All these sp. occur in the tops of old pines. The lower bole regions are occupied by *Ips typographus* and *I. amitinus*. As the tree decreases in health *P. chalcographus* increases and descends, mixing with the *Ips* spp. The same sort of thing occurs in spruce, *Cryphalus picae*, *Pityokteines spinidens*, and *P. curvidens* occur, and the spp. characteristic of firs, *P. chalcographus* and *P. micrographus* (above), which occasionally occur also on spruces. The associations on *Pinus montana* are generally composed of *Pityogenes bidentatus* and *Pityophthorus glabratus*, and on *P. silvestris* of *Blastophagus piniperda*, *Pityogenes bidentatus*, *Ips naturalis*, *I. amitinus* and *I. acuminatus*. In Bukowina there is only 1 generation of *I. acuminatus* but 2 of *Xyloterus lineatus*. —*From author's summary* (*transl.*).

(See also in B. A. 6(5): Entries 12366, 13630, 13856, 13885, 13902, 13904, 14762, 14787, 14843, 14846; and in this issue 16581, 16790, 16801, 16802, 16826, 16829, 16989, 17702, 17705, 17786, 17799, 17800, 17809, 17822)

16834. **BLUNCK, HANS.** Über die Parasiten der Rohrglanzgrasgallmücke Mayetiola phalaris Barnes. *Zeitschr. Angewandte Ent.* 18(3): 582-589. 1931.—*Trichacis remutus*, *Polygnotus minutulus*, *Platygaster hiemalis*, *Phygadeuon* cf. *monodon*, *Semiotellus destructor*, *Meraporus graminicola*, *Entedon metallicus* and *Tetrastichus rileyi* are discussed.

16835. **BROWN, F. MARTIN.** Bacterial wilt disease. *Jour. Econ. Ent.* 23(1): 145-146. 1930.—*Staphylococcus flaccidifex* obtained from 7 spp. of lepidopterous larvae affected equally all lepidopterous larvae used. In the laboratory, using *Pyrameis huntera* and *Callosamia promethea*, the disease caused by this organism was highly successful both as to fatality and contagion, but under field conditions poor results were obtained.—*F. E. Whitehead.*

16836. **CARIÉ, PAUL.** La destruction des "Opuntia" à l'île Maurice. [Destruction of Opuntia in Mauritius.] *Rev. Hist. Nat. Pt. 1. B. Aquicult., Ent., Aquar. et Terrar.* 10(5): 174-176. 2 pl. 1929.—Experiments with the cochineal insect, *Dactylopius indicus*, are described.

16837. **CHATER, E. H.** A contribution to the study of

the natural control of gorse. *Bull. Ent. Res.* 22(2): 225-235. 1931.—At the request of the government of New Zealand, where the plant is a pest, a study of gorse (*Ulex europaeus*) has been made in England. It thrives on soils deficient in Ca. The annual cycle, methods of spread by adventitious rooting and seed dispersal, seed mortality, and insect damage are discussed. The greatest damage is done by *Apion ulicis*, which breeds in the flowers. The flowers are also attacked by *Depressaria costosa* and *Anarsia spartiella*, but the larvae of the latter migrate to the tips of young shoots, where they are parasitized by *Paralitomastix varicornis, Pimpla inquisitor, P. detrita, Microbracon stabilis*, and *Phaeogenes* sp. The pods are damaged by *Apion ulicis, Laspeyresia ulicitana* and *Coleophora albicosta*. *Apion scutellare* is found on *Ulex minor* and *U. gallii*. *Asphondylia ulicis* forms galls on the flower buds. Unsuccessful efforts have been made to introduce *Apion ulicis* into New Zealand.

16838. **CLARK, ARTHUR F. The parasite control of Gonipterus scutellatus Gyll.** *New Zealand Jour. Sci. and Technol.* 13(1): 22-28. 10 fig. 1931.—*Gonipterus scutellatus* is an Australian defoliator on *Eucalyptus globulus, E. viminalis, E. radiata, E. gunnii*, and *E. macarthuri*, and rarely on *E. linearis* and *E. amygdalina*. Its life history is described. *Anaphoidea nitens* parasitizes the eggs. Its egg*, larva*, pupa*, and adult* are described. *Cermatulus nasalis* final-instar larvae* and adults have been observed to feed upon the weevil larvae, although they also feed on *Eucalyptus* leaves.

16839. **FERRIÈRE, CH. Parasites de Perrisia pyri, Bouché (Dipt., Cecidom.).** *Bull. Ent. Res.* 17(4): 421-422. 1927.—The parasites of the pear midge, *Perrisia pyri*, in France, are: Scelionidae—*Isostemma boscii*, and *Misocyclops marchali;* Chalcidoidea—*Torymus abbreviatus, Eurytoma aciculata, Tetrastichus brevicornis* and *Entedon* sp.; and possibly Diapriidae—*Trichopria* (*Planopria*) sp. The 3 first named are most important.

16840. **GROSSMAN, EDGAR F. Insect enemies of the cotton boll weevil.** *Florida Ent.* 15(1): 8-10. 1931.—Records of percentage of parasitism of the boll weevil, *Anthonomus grandis*, in Florida, Georgia, and Alabama in 1927 and 1930.

16841. **IMMS, A. D. Remarks on the problem of the biological control of noxious weeds.** *Trans. 4th Internat. Congr. Ent., Ithaca* 1928. 2: 10-17. 1929.—The general principles upon which the biological control of noxious weeds is based are discussed. The precautions necessary in selecting suitable types of insects for plant control, and in introducing them into other lands, are stressed. The bearing of the host-selection principle also finds place in this discussion. The scheme of control of blackberry (*Rubus fruticosus*), ragwort (*Senecio jacobaea*) and gorse or furze (*Ulex europaeus*) in New Zealand is described. Reference is made to work carried out on this problem in connection with insect enemies of the above plants at the Rothamsted Experimental Station, and a short account given of methods adopted in shipping living insects to New Zealand.—*A. D. Imms.*

16842. **JAZYKOV, AL. A. Parasites and hyperparasites of the egg-pods of injurious locusts (Acridodea) of Turkestan.** *Bull. Ent. Res.* 22(3): 385-391. 1931.—*Epicauta erythrocephala* (Meloidae) parasitizes the egg-capsules of *Calliptamus italicus, Locusta migratoria*, and occasionally *Schistocerca gregaria;* its life history is sketched. The pseudopupa resting stage can be repeated during an individual development 2 or 3 times. A diapause, lasting many yrs., of some of the pseudopupae of each brood was regularly noticed. *Mylabris frolovi* (Meloidae) parasitizes the eggs of *Dociostaurus maroccanus, D. kraussi, Calliptamus italicus*, and *C. turanicus*. *M. deserta* is distinct: it parasitizes *Dociostaurus maroccanus, D. kraussi*, and *Ramburiella turcomana;* *M. tekkensis* parasitizes the eggs of *D. maroccanus;* *M. scabiosae scabiosae* the eggs of *D. maroccanus, D. kraussi, D. crucigerus tartarus*, and *R. turcomana;* *M. 4-punctata* the eggs of *Cal. italicus;* *M. biguttata* the eggs of *R. turcomana;* *M. atrata* is distinct, but its host is unknown. *Trichodes* larvae (Cleridae) were found in eggs of *R. turcomana, D. kraussi*, and *D. maraccanus*. *Callistoma desertorum* (Bombyliidae) is a valuable parasite of *D. maroccanus, Calliptamus turanicus*, etc.; *Cytherea setosa* parasitizes the eggs of *Calliptamus italicus;* *Anastoechus nitidulus* the eggs of *Cal. italicus*, and *C. turanicus;* *A. baigakumensis* the eggs of *Locusta migratoria;* *Hemipenthes* (*Thyridanthrax*) **pallidipennis** Paramonov (in litt.) (p. 390), undescribed, Tashkent, parasitizes eggs of *D. maroccanus;* *Anthrax oophagus* Paramonov (in. litt.) (p. 390), undescribed, (will be described in a forthcoming paper by Paramonov), data on life history, parasitizes the eggs of *Dociostaurus maroccanus, D. kraussi, D. crucigerus tartarus, Ramburiella turcomana*, and *Calliptamus turanicus*, and may become hyperparasitic on *Callistoma* [*d.*] and *Mylabris biguttata*, inhabiting the egg pods; *A. monachus* attacks the egg pods of *R. turcomana* and hyperparasitizes *Mylabris s. scabiosae* in the pods; *A.* **jazykovi** Paramonov (in litt.) (p. 390), undescribed, is close to *A. zonabriphagus* and parasitic on the prepupae of *Epicauta erythrocephala* in the Zeravshan Valley; data on life history. *Oophagomyia plotnikovi* (Tachinidae) is rare in the egg pods of *Schistocerca gregaria* and *Locusta migratoria;* *Stomatorhina lunata* is parasitic in eggs of *S. gregaria*. *Scelio nikolskyi* (Hymenoptera) attacks eggs of *Locusta migratoria*. Its true type locality is Maidan-tal district, Tashkent Prov., and not Perovsk.

16843. **MUIR, F. The critical point of parasitism and the law of Malthus.** *Bull. Ent. Res.* 22(2): 249-251. 1931.—The "critical point of parasitism" is defined as the point when the parasite can exist but can produce no further effect upon the host population. Various cases of parasite introduction and effect upon the hosts in Hawaii are discussed. The use of overlapping death factors is defended.

16844. **RILEY, WILLIAM A. Erasmus Darwin and the biologic control of insects.** *Science* 73(1896): 475-476. 1931.—Historical note on Erasmus Darwin as a forerunner of modern economic entomologists in use of insecticides and biological control.

16845. **SCARAMUZZA, L. C. Preliminary report on a study of the biology of Lixophaga diatraea Tns.** *Proc. Ann. Conf. Asoc. Tecn. Azucareros Cuba* 4: 59-63. 1930.—This Tachinid is the most important larval parasite of the sugar cane moth borer, *Diatraea saccharalis* Fbr., in Cuba. Parasitism reaches 40% during spring and summer. The flies are larviparous, and borer larvae can be inoculated by dissecting gravid ♀♀ and placing maggots on the host. There are 3 larval stages, of which part of the 1st and 2nd are attached to the trachea of the host while the 3rd is always free within the host body. 6-7 days are required for the pre-larvaposition period, 5.5-13 days in the larval stages, and 9-11 days in the pupal stage.—*Author's abstract.*

16846. **SITOWSKI, LUDWIK. O pasorzytach barczatki (Dendrolimus pini L.) i mniszki (Lymantria monacha L.). [The parasites of D. pini and L. monacha.]** [With German summary.] *Roczniki Nauk i Leśnych (Polish Agric. and Forest. Ann.)* 19(1): 1-12. 1928.

16847. **STEINER, PAUL. Zur Kenntnis der Parasiten des Kiefernspanners.** *Zeitschr. Angewandte Ent.* 17(3): 601-630. 7 fig. 1931.—*Trichogramma evanescens* Wests. and *Telenomus* sp. were obtained as egg parasites, and are favored by mixed forests. The ratios of egg parasitism in pure stands of pine, in stands of pine with an undergrowth of fir, and in mixed forests were 17, 66: 37, 62: 49, 2. Parasites of the larvae or pupae of the pine moth of practical significance are the ichneumonids, *Anomalon biguttatum* Grav., *Ichneumon nigritarius* Grav., *Heteropelma calcator* Westm. and *I. locutor* Thunb., and the tachinids, *Lydella nigripes* Fall. and *Carcelia rutilla* B.B. The total number of reared ichneumonids and tachinids were in the ratio of 1043:1871. Before the climax of the outbreak the ichneumonids were most strongly represented, after its culmination the tachinids. *I. nigritarius* develops only one generation annually in Mecklenburg and passes directly from one generation of the pine

moth to the other. Rearings at the beginning of the outbreak in 1928 exhibited a parasitism of 27% of the pupae, of 41.94% at the peak of the infestation in 1929, and 62.635% during its decline in 1930. Fungous and bacterial diseases were also potent factors regulating the population of the pest. Unparasitised pupae show a higher mortality, on account of disease, than parasitised pupae. Mortality in the unparasitised pupae and in those that contained ichneumonids is higher than the average, but among those parasitised by tachinids it is less. Supernumerary parasitism results in a contest which is won by the species having the fastest rate of development. *I. nigritarius* is not affected by the concurrence of other species. Tachinids are at a disadvantage as compared with *I. nigritarius*, but at an advantage as compared with the late emerging *H. calcator* and *A. biguttatum*. The latter suffer most seriously from superparasitism. Neither the parasites of the eggs nor of the larvae were threatened by a single application of poison in a year. Present knowledge does not furnish ground for stopping the spraying for the preservation of the parasites. The methods practised today in the study of pine moth parasites are explained.—*Author's summary (transl. by W. V. Balduf)*.

16848. **STRUBLE, GEORGE R. The biology of certain coleoptera associated with bark beetles in western yellow pine.** *Univ. California Publ. Ent.* 5(6): 105-134. 6 fig. 1930.—Life-histories are presented of 4 spp. of beetles in an attempt to find their value as a control for *Dendroctonus brevicomis* Lec. Full descriptions with figs., of egg, larva, pupa, and adult of each sp. are given. *Platysoma punctigerum* Lec. (Histeridae) overwinters as adult. Eggs are laid in May in small groups. Larvae are voracious predators; they mature in 4-6 weeks. This species has some slight value as check on *D. brevicomis*. *Plegaderus nitidus* Horn (Histeridae) overwinters as larva and adult. Eggs are laid in May and June; pupation occurs in September; overwintering larvae mature in July. It may prove valuable in control. *Hypophloeus substriatus* Lec. (Tenebrionidae) overwinters as larva and adult. Eggs laid in small groups in bark beetle burrows in June hatch in 10 days, pupate 10 days, adults emerge in September. Overwintering larvae develop in August. This is of little value in control because it feeds almost entirely on fungi. *Nudobius pugetanus* Csy. (Staphylinidae) overwinters as larva and adult. Eggs laid in June singly, larvae develop rapidly, pupate in August, adults appear in September. Overwintering larvae develop in late June. It is not valuable in control.—*J. C. Pallister*.

16849. **THORPE, W. H. The natural control of Hyponomeuta padellus L.** *Proc. Ent. Soc. London* 5: 28-30. 1930.—Nine spp. of Hymenopterous parasites and hyperparasites are recorded as attacking *H. padella*, L. (Lep.) in Sussex, England. The most important are *Herpestomus brunnicornis* Grav., *Angitia armillata* Grav., and *Ageniaspis fuscicollis* Dalm. Evidence is brought forward to show that these species are important in the control of moths of this genus.—*W. H. Thorpe*.

GENERAL

16850. **BOHSTEDT, G. The effect of mineral additions to practical swine rations.** *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 222-225. 1930(1931).—Experiments involving 260 young brood sows showed that neither complex nor simple mineral mixtures had a beneficial effect when added to a good practical brood sow ration. The young sows were fed from about weaning time to the time that they farrowed their first litters; each experiment, therefore, covered about one year. The basal ration consisted of corn, oats, wheat middlings, tankage, linseed meal, and ordinary flake salt, with alfalfa pasture in the summer and alfalfa hay in the winter in addition. The minerals consisted of bone meal, or bone meal and potassium iodide, or ground limestone, or rock phosphate, or a mixture of bone meal, limestone, sulphur, potassium chloride, Glauber's salts, Epsom salts, copperas, and potassium iodide. None of the mineral additions when added to the basal ration which contained tankage and legume pasture or hay, caused any consistent improvement with respect to rate of gain, economy of gain, or vigor of offspring produced.—*G. Bohstedt*.

16851. **CAVALLI, ROBERTO. L'ingrassamento economico dei maiali. Prove pratiche eseguite con l'impiego di mangimi meno usati. [Practical experiments carried out with less common feeds.]** *Riv. Zootecnia [Firenze]* 8(7): 277-293. 1931.—The use of corn and bran is not the most economical for fattening hogs in regions where milk by-products are not available. Optimum results are obtained from ground manioc, barley bran, coarse rice flour, meat meal, etc. Animals on these feeds gain 0.84-0.95 kgm. per day, and gain more cheaply, while the traditional feeds of corn and bran produce an increase of only 0.75 kgm. per day.—*Author's conclusions (transl.)*.

16852. **CLAUSEN, HJALMAR. Beitrag zur Frage des Eiweissoptimums bei Mastschweinen.** *Züchtungskunde* 6(8): 289-304. 1931.—For the development period of 30-90 kgm. the average daily optimum of digestible protein is 250-275 gm. Increasing the daily protein up to this amount causes (1) a greater daily increase in wt., (2) lower food requirement per kgm. added, and (3) less fat but more meat. Only grain and skim-milk were fed; if skim-milk is replaced by blood meal, the latter is as good as skim-milk, but the hogs consume less.—*From author's summary (transl.)*.

16853. **DASSAT, PIERO, e FURIO CANNAVO. Frodi e inganni nel commercio dei bovini. [Frauds and deceptions in the cattle business.]** *Riv. Zootecnia [Firenze]* 8(8): 320-335. 5 fig. 1931.—Methods are described of changing the physical appearance of cattle in order to deceive concerning their condition, age, etc.

16854. **DUMITRESCU, N. A. Cercetari asupra valorii nutritive a porumbului vechiu. [Nutritive value of maize for swine.]** *Ministerul Agriculturii si Domeniilor [Bucarest]* 4/5: 1-512. 12 fig. 1929(1930).—It is not only the spoiled fresh maize that produces serious disturbances given as the sole food of swine, but also unspoiled old maize of good quality. Although it contains a considerable quantity of all the food principles which have been considered as sufficient for sustaining animal life, maize is not a complete food because its proteins lack tryptophane and contain but little glycocoll, cystine and lysine, and also because of its deficiency in vitamins and vitasterols, proof of which is found in the manifestation of certain maladies, such as paralysis of the legs, analogous to rachitic phenomena; cutaneous eruptions very similar to those of pellagra; and xerophthalmic phenomena, produced by the lack of certain vitamins and vitasterols in the food (vitasterol E, vitamine P (?) and vitamine A). Swine fed exclusively on cornmeal mush show the pathologic phenomena in much accentuated form and suffer much more than animals fed on the raw maize grain. This proves that the seed coat

of maize, partly eliminated in sifting the meal, contains traces of amino acids, vitamins and vitasterols; hence the whole grain and the unsifted meal are more nourishing than the sifted cornmeal. After a while the blood of the pig fed exclusively on maize or on cornmeal mush forms zeinolithic ferments for the defense of the organism against the maize protein (zein). Zein penetrates into the blood without undergoing digestion by the gastric juice, particularly following the frequent gastro-intestinal disturbances occurring in swine fed exclusively on cornmeal mush. Neither the wheat grain nor the bread given to swine, instead of the maize grains and cornmeal mush on which they had fed for 84 days sufficed to restore them to health or to prolong their life greatly.—*Author's conclusions (transl. by W. E. Joseph).*

16855. DU TOIT, P. J. The value of phosphorus in the cattle industry of South Africa. *S. African Jour. Sci.* 26: 373-385. 1929.—South African soils and pastures are particularly deficient in phosphorus. This is evidenced by stunting of cattle grazing on the veld, low milk yields, infrequent calving, and the prevalence of lamsiekte. Theiler showed this disease could be prevented by feeding bone meal. Experiments were begun at Armoedsvlakte in 1925 in which purebred bulls of the Friesland, Redpoll, Sussex, and Africander breeds were mated with 200 scrub cows to determine whether high class stock could be maintained on the veld or whether they would revert to stunted or scrub stock. Two-thirds of the cows were fed 5 oz. bone meal per head 6 days a week, the other third serving as controls. During 3 years, the bone meal group produced 87.3% of the possible number of calves compared to 56.5% for the control group. No significant differences between birth weights of calves of the 2 groups were found. The bone meal fed cows produced nearly 70% more milk than the controls. At weaning age of 9 months, calves from bone meal fed mothers weighed 14% more than the controls; at 2 yrs, with bone meal feeding of calves from bone meal mothers begun at weaning, the difference had reached 33%. Twenty bone meal fed oxen and 8 controls were slaughtered at 3 years of age. The controls weighed 62% as much and dressed weights were 46% compared with 50% for the bone meal group. The quality of the beef of the controls was poor, selling for a little more than half the price per pound of the bone meal fed animals. Bone meal feeding induced greater skeletal development, prevented craving for bones, and reduced the incidence of disease. Commercial dicalcium phosphate containing 43 per cent P_2O_5 (compared to 22 per cent in the bone meal) was found slightly more efficient and economical than bone meal.—*W. B. Nevens.*

16856. GIULIANI, R. Le barbabietole da zucchero nell'alimentazione del bestiame. [Sugar beet roots as feed for domestic animals.] *Riv. Zootecnia [Firenze]* 8(7): 301-304. 1931.—For fattening hogs sugar beets are better cooked than raw, but need protein supplements. Sugar beets may advantageously be added to the feed of oxen, fattening cattle, goats, and sheep. Oxen can consume 25 kgm. per day and fattening cattle as much as 30 kgm. Lactating goats and sheep derive a great benefit from sugar beets to which is added some concentrate.

16857. GIULIANI, R. L'alimentazione del cavallo da tiro. [Feeding of draft horses.] *Riv. Zootecnia [Firenze]* 8(8): 345-351. 1931.

16858. GRONOVER, A., und F. TÜRK. Untersuchung von Milch unter Berücksichtigung ihrer Lichtbrechung. *Zeitschr. Untersuch. Lebensmittel* 61(1): 85-94. 3 fig. 1931.—By means of the Zeiss refractometer the refraction of light in milk may be determined directly, without first removing the protein and fat. The attempt to use a short cut in detecting adulteration of milk with water by this method is based on the assumption that the dry matter content, which determines the degree of refraction, and the refraction are proportional within narrow limits. On the basis of a large number of tests made, it is evident that this assumption is not valid, and that the variations are so great that this method can not be used for practical deductions concerning the composition of milk.—*A. Gronover (transl. by A. H. Kuhlman).*

16859. HANNSSON, NILS. Einfluss der verschiedenen Bereitungsweisen auf die Verdaulichkeit und den Futterwert der Getreidearten. [With English summary.] *Biedermanns Zentralbl. Agrikulturchem. u. Rationn. Landwirtschaftsbetrieb Abt. B. Tierernähr.* 3(3): 243-274. 1931.—In tests, chiefly with fattening swine, mere crushing of the grains increased the utilization by about 5-6%. When the grains are ground into coarse groats, which have a content of fine meal (i.e., a meal able to pass a sieve with meshes of 1 mm.; for the rest, groats of normal coarseness are to contain only particles of a diameter smaller than 3 mm.) of about 45-50%, the effect increases about 10-12% of that of the whole grain; when the grains are ground into fine groats (85-95% fine meal), about 15-18%. These data on swine seem to hold good in the main also for horses, and to a certain extent also for fowls. So-called maize-flakes (Maisflocken), prepared by crushing, cooking, rolling and drying the maize-kernel, seem to have the same digestibility and the same feeding-value as finely ground maize. Soaking of whole, crushed, or ground grain did not increase digestibility nor feeding-value. Cooking the whole or ground grain increased its digestibility or utilization only slightly, and in no case at a rate corresponding to the cost of cooking. On the contrary, cooking greatly impaired the keeping quality of grain and groats. The fermentation of concentrates did not increase their digestibility, nor their efficiency. The so-called "Biovita"-method is considered worthless if the concentrates are used in well balanced rations. Young pigs often suffer intestinal troubles if shifted too quickly to a diet high in maize. Good results were obtained with 50% maize in the concentrates (later, almost 75%) with pigs averaging 20-45 kgm. If the maize was fed with an abundance of dairy by-products, no ill effects on the firmness of the lard were noted, even when the concentrates contained 75% maize. In general there is full agreement between the results of the digestion trials and of the practical feeding trials.—*From author's summary.*

16860. HILLS, J. L. A third of a century of feeding-stuff inspection. *Vermont Agric. Exp. Sta. Bull.* 324. 1-48. 10 fig. 1930.—In this publication the author pictures the status of feeding stuffs prior to the passage of the feed control law and compares it with the situation after the law had been in effect for a few years and with the present status of feeding stuffs. The results in terms of guaranty maintenance by present-day licensees over a period of several years are given in table form. The amount of feeding stuffs used in the state, in several of the counties, and the per farm usage covering the period from 1910 to 1925 are also given in table form. The relationship of the use of feeding stuffs to milk production is presented.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

16861. HORLACHER, L. J. Factors involved in the fattening of show wethers. *Amer. Soc. Animal Product. Ann. Meet.* 23: 190-191. 1930(1931).—A comparison of breeds shows that Hampshire wethers make the most rapid gains, followed in order by grades, Southdowns, and Cheviots. Yearling wethers and wether lambs gain at the same rate. The smallest gains were made during the periods of highest temperature.—*L. J. Horlacher.*

16862. ISAACHSEN, HAAKON, und OLA ULVESLI. Die Kontrolle des Futterverbrauchs und der Gewichtszunahme bei Pferden (Östlands Pferden) im Alter von 1/2 Jahr bis zu etwa 3 Jahren. [Control of consumption of fodder and increase in weight with Östland horses from the age of 6 months to about 3 years.] [Translated from the Norwegian by EUGEN BASS and EUGEN BASS, Jr.] *Zeitschr. Gestütk. u. Pferdezucht* 26(2): 17-22. 1931.—(See also B. A. 5(10): 24336.)

16863. JOSEPH, W. E. Relation of size of grade fine wool ewes to their production. *Montana Agric. Exp. Sta. Bull.* 242. 1-15. 8 fig. 1931.—There was a progressive

increase in the weights of the average lamb crops as the weights of the ewes increased. There was an extreme spread of 21 lb. between the weight of the lamb crops from the lightest to the heaviest ewes. There was also a tendency for the heavier ewes to raise a larger percentage of twins and to raise pairs of twins that were heavier. The heavier ewes also produced heavier fleeces with a maximum spread of 1 lb. These tests were also conducted with 88 ewes out of the foundation ewes and sired by Rambouillet rams. Although these ewes averaged 20 lb. heavier than their dams, the relations between the weights of average lamb crops and weight of ewes was the same. Practically the same results were obtained in regard to twins and to wool production. The results show that culling the small ewes would not have eliminated any exceptional lamb producers and few were equal to the average. There were no indications that one weight class of ewes had any tendency to fail to produce a lamb crop more often than any other class. Preliminary results indicated that the size of a ewe was a more accurate measure of her ability to raise heavy lamb crops than was the lamb-producing ability of her dam. While size was not the sole criterion in selection, this work shows that it was the most accurate single measure for the selection of fine wool ewes.—*H. W. Marston (courtesy Exp. Sta. Rec.)*.

16864. **JUDKINS, HENRY F. The principles of dairying, testing and manufactures.** 2nd ed. rev. by RICHARD W. SMITH Jr. 322p. 85 fig. John Wiley & Sons: New York, 1931.

16865. **KLIESCH, J. Fütterungsversuche an Schweinen mit "P_3" (Chlorkalziumpräparat). Ein Beitrag zur Frage des Mineralstoffbedarfs der Schweine.** *Zeitschr. Züchtung B. Tierzücht. u. Züchtungsbiol.* 21(1): 194-200. 1931.—The investigation was conducted on pigs being rapidly fattened for market. The 5 experimental groups received the same basal ration to which different mineral salts were added. One group received no special mineral salt. The group that received the "P_3" (a $CaCl_2$ preparation), and the one that received pulverized chalk as the added mineral salt showed no difference in development. Apparently the swine on a correctly compounded fattening ration need no special mineral salts in addition. The group that received no additional mineral salts (although this may in part be due to the fact that the animals of this group were somewhat heavier at the beginning) and the group receiving "P_3" in combination with "Vigantol" developed the best. Whether the result was accidental could not be determined on the basis of one group. An earlier fattening experiment had shown with foods rich in vitamin D, that the enrichment of a normally compounded ration with vitamin D has no effect on the success of fattening in healthy swine.—*Author's summary (transl. by W. E. Joseph)*.

16867. **MONDOÑEDO, MARIANO, and FIDEL ALONTE. A comparative study of corn, cassava, sweet potatoes and pong-apong as feeds for swine.** *Philippine Agric.* 20(2): 113-119. 1931.—Cassava and sweet potato (camote) have about the same feeding value; pong-apong a somewhat lower feeding value. When compared to corn for feeding pigs, about 5 months of age or over in dry lot, 2.3 parts by weight of cassava or camote and 2.67 parts of pong-apong are equivalent to one part of corn.—*M. Manresa.*

16868. **MURO, EGIDIO de. Il nutria ed il sio allevamento. [Nutria and nutria-raising.]** *Riv. Zootecnia [Firenze]* 8(7): 293-300. 3 fig. 1931.

16869. **NEVENS, W. B. Feeding the dairy herd.** *Illinois Agric. Exp. Sta. Circ.* 372. 1-52. 15 fig. 1931.—A popular publication describing the feeding of various classes of dairy cattle. The characteristics of the ideal ration, the composition of feeds, calculating the relative economy of feeds, a simple method of balancing rations, some common problems in dairy feeding, and the feeding value and quality of individual feeds are also described. —*H. W. Marston (courtesy Exp. Sta. Rec.)*.

16870. **OTTEN, C. Die Ernährung und Aufzucht des rheinisch-deutschen Kaltblutfohlens. [Feeding and raising of Rhine-German Cold-blood colts.]** *Anleit. Deutsch. Ges. Züchtungsk.* 14. 1-20. 1931.—Feeds, care, and diseases are discussed.

16871. **PARISI, OTTAVIO. Esperimento di incrocio fra pecore gentili di Puglia e Garfagnine. [Crossing of sheep from Puglia and Garfagnana, Italy.]** *Riv. Zootec. [Firenze]* 7: 347-368. 8 fig. 1930.—Puglia sheep were unsatisfactory in low or damp areas. To produce satisfactorily they require mountain climate and high quality feeds. Attempts to acclimate them in lower levels resulted in diminished fecundity and reduced milk production which was not compensated by the increased wool production resulting. It was therefore considered impracticable to raise this breed pure in Garfagnana (part of Tuscany). Better results were obtained from the first generation crossbreds. Milk production was only slightly inferior to that of the Garfagnana sheep, while the wool was finer and its quantity was doubled. For meat production the crossbreds, although considerably smaller-framed than the Garfagnana breed, were generally fatter and there was no appreciable difference in weight. The good results obtained with the F_1 crossbreds (simple crossing) need to be checked in later generations. Especially is it indispensable to discover experimentally the method of crossing most advisable for adoption.—*Author's conclusions (transl. by E. N. Wentworth)*.

16872. **PATERSON, WILLIAM G. R. Cattle feeding. Swedes versus potatoes for beef production.** *Trans. Highland & Agric. Soc. Scotland* 43: 86-99. 1931.—Nine Blue-Grey (Shorthorn-Galloway cross) and nine Galloway bullocks with common ration of concentrates, hay and oat straw were fed in 3 groups receiving (1) 72 lb. swedes, (2) 36 lb. swedes, 16¼ lb. potatoes, (3) 32½ lb. potatoes. These amounts supplied equivalent weights of dry matter. Half the potatoes were Kerr's Pink and half Arran Chief variety; a third of total were chats. Blue-Greys were conditioned in 12 weeks; Galloways in 14 weeks. Average weekly live weight increase for Group (1) 12.4 lb. (2) 13.1 lb. (3) 13.6 lb. The percentage carcase weights to unfasted live weights were for Group (1) 57.8 (2) 58.1 (3) 58.9. The average for all the Blue-Greys was the same as for all the Galloways, 58.3. Examination of carcases showed little difference in quality of meat. From the expenditure and receipts it is calculated that 13/2d per ton was returned for swedes and 44/- for potatoes. Exclusive of moisture in roots the water consumption in gallons per head per day was, Group (1) 1.94, (2) 3.17, (3) 4.71.—*A. F. R. Nisbet.*

16873. **ROMANICKÝ, ALEX. Příspěvek k morfologii a biologii koně Przewalského (Equus przewalskii Polj.). [Morphology and biology of the Przewalski horse.]** *Zemědělský Archiv [Prague]* 21(3/4): 111-129. 6 fig. 1930.

16874. **SAITO, M. Some investigations on the freezing point of milk and its relation to the protein coagulation.** [In Japanese, with English summary.] *Bull. Miyazaki Coll. Agric. and Forestry* 3. 9-20. 1931.—Fresh Holstein milk has a freezing point of −0.530 to −0.585° C. (ave. −0.555); from Japanese breed, −0.530 to −0.575 (ave. −0.551). Milk having an acidity of more than 0.18% begins to show a depression of its freezing point below −0.555° C., the amount of the depression being approximately proportional to the acidity. When milk is coagulated by adding 0.92% of lactic acid by wt., the freezing point of the coagulated milk is lowered about 0.223° C. (ave.); lactic acid in water in the same concentration depresses the freezing point only 0.197° C. Rennet-coagulated milk tends to elevate its freezing point slightly (.0006° C.). Heating at 95-100° C. for 2 hrs. causes no appreciable change in freezing point.—*From author's summary.*

16875. **SCHARRER, K., und K. KÜRSCHNER. Ein neues, rasch durchführbares Verfahren zur Bestimmung**

der Rohfaser in Futtermitteln. [With English summary.] *Biedermanns Zentralbl. Agrikulturchem. u. Ration. Landwirtschaftsbetrieb Abt. B, Tierernähr.* 3(3): 302-310. 1931.—Three gm. of the feed (when homogeneous material is used only 1 gm., with corresponding reduction in reagents) are boiled in a reflux-condensor with 75 cc. acetic, 5 cc. conc. HNO_3 and 2 cc. trichloracetic acids. The material is filtered through a Gooch crucible, washed thoroughly with distilled H_2O, afterwards with alcohol and ether, dried at 100-110°, cooled in a desiccator, and weighed. Afterwards the crucible is heated in a muffle-furnace, with complete combustion of the organic substance. The loss of wt. between the 1st and the 2nd wt. represents the quantity of crude fiber.—*From authors' summary.*

16876. **SCHAUBE, GERHARD. Vergleichende Haaruntersuchungen am Kaninchenfell im Hinblick auf den Einfluss verschiedener Umweltfaktoren und unter besonderer Berücksichtigung der Pelzqualität.** *Wiss. Arch. Landw. Abt. B, Arch. Tierernähr. u. Tierzucht* 6 (2): 160-194. 13 fig. 1931.—To study the influence of external factors upon the hair covering, rabbits were kept under 4 different sets of environmental conditions. These different types of management appeared to have practically no influence upon the length and fineness of the downy underhair. The growth in length and diameter of the cover and guard hair was greater if the animals were kept outdoors than if they were kept in the warmer inside pens. Among the cover hair a positive correlation was found between length and diameter ($r = 0.3501 \pm 0.02925$). Among the underhair a low positive correlation was found between length and diameter ($r = 0.144 \pm 0.019$). The density of hair growth is definitely influenced by the environmental conditions; the differences in density (number of hairs per unit area) under the different environmental conditions varied up to 25%. No reciprocal relation seemed to exist between density of the underhair and fineness of the hair. Under identical feeding conditions the nutrition of the animals and the condition of the skin are influenced indirectly by the environment (e.g., temperature); this in turn greatly influences such fur qualities as resistance of the hair roots to pull, moulting, and so on. For the production of good fur qualities outdoor breeding appears to be best.—*Author's summary (transl. by W. Landauer).*

16887. **CHLEBAROFF, G. S. The fertilization of hens' eggs.** *World's Poultry Congress* 4 (Sect. a): 6-11; résumé sect., 2. 1930.—After segregation of the cock from the hens, the last fertile egg is most frequently laid at the end of the 2nd week, more rarely in the course of the 3rd week, and not later than the 19th day. The 1st egg fertilized by any one cock is laid on the 2nd day, irrespective of whether the last mating took place in the morning or evening. The number of eggs fertilized at one mating varies greatly, and depends on the intensity with which the hens are laying and on the sexual vigor of the cock. In the present tests the number was up to 8 eggs.—*Author's conclusions.*

16888. **CRESPO, RAMÓN J. Gallinas y gallineros. [Poultry and poultry culture], curso completo de avicultura adaptado al programa oficial publicado por el Ministerio de Fomento para la obtención del Título de Avicultor, previo examen ante los Tribunales competentes.** Libro 3. 406p. Illus. Ramon J. Crespo: Madrid, 1930.

16889. **FAWKES, A. K. Review of some breeding experiments carried out at the U. P. poultry association's demonstration farm, Lucknow.** *Madras Agric. Jour.* 19 (1): 2-6. 1931.—These experiments were carried on to produce a breed of egg-producing fowl more tolerant of the Indian climate. One of the most successful crosses was between pure Busra hens and a white Leghorn ♂. Egg production and size of egg were remarkable, and broodiness was almost eliminated.

16890. **FRONDA, F. M., and GAUDENCIO B. CRUZ. Preliminary studies on the possibilities of "green duck" production.** *Philippine Agric.* 19(9): 591-600. 1931.—Green ducks when properly fed make most rapid gains the 1st-7th weeks; subsequently the gains gradually diminish so that maximum profits are secured when the birds are 7-8 weeks old. The ♂♂ are easily recognized as early as 3 days after hatching by a tiny knob-like projection at the cloaca; this method has been practiced by Philippine duck raisers, for many years.—*M. Manresa.*

16891. **FUNK, E. M. Growth and feed consumption of turkeys raised in confinement.** *U. S. Egg and Poultry Mag.* 36(8): 23-25. 1 fig. 1930.—Tabulated results show the feed consumed by months by 100 Bronze and 100 White Holland turkeys. Tables also show the relative efficiency of the 2 varieties to use feed for growth and also the effect of age upon this efficiency. The most efficient gains are made during early life.

16892. **FUNK, E. M., and P. H. MARGOLF. Feed consumption and costs in raising turkeys.** *Pennsylvania Agric. Exp. Sta. Bull.* 250. 11p. 3 fig. 1930.—134 Poults of the Bronze and White Holland varieties were fed for 24 weeks. The poults were hatched in an incubator operated much the same as in hatching chicks, and were brooded in a long continuous house. Until 20 weeks of age they were fed by the all-mash method on a ration composed of yellow corn meal, wheat bran, wheat flour middlings, alfalfa leaf meal, dried buttermilk, fish meal, meat scrap, steamed bone meal, salt, and cod-liver oil. Water and liquid buttermilk were before the poults at all times until the 19th week, when condensed buttermilk

was substituted for the liquid. At 8 weeks of age ground oats was added to the mash, and at the 17th week 5 lb. of corn meal was substituted for a like amount of dried buttermilk. At 20 weeks equal parts of corn and wheat were fed in the mash hoppers. Green feed was before the birds at all times. The poults were confined until 18 weeks of age, when they were turned on range to minimize feather picking. Each poult was wing banded and weighed individually every 2 weeks to 16 weeks of age and then every 4 weeks. At the end of the test the live weight, blood and feather weight, and full-drawn weight of each turkey were determined. A growth faster than any previously reported was obtained in this study. The mash and grain consumption per bird for 24 weeks was 58.05 and 56.12 lb. for the Bronze and White Holland varieties, respectively, and the cost per pound of gain 14.7 and 15.3 cents respectively. The feed required to produce a pound of gain increased from 2.56 to 7.71 lbs. as the poults matured. A protein level of about 20% was maintained until the 18th week, and then decreased to 14.8% at 24 weeks. The mortality rate was less than 7%. Under the confinement system excellent market birds were produced. The blood and feather dressing loss for ♂♂ was 9.5%, for ♀♀ 10.4%; the total shrinkage based on full-drawn weight was 24.2% for ♂♂, 24.7 for ♀♀. The differences were due to size, not to sex.—*H. W. Marston (courtesy Exp. Sta. Rec.)*.

16893. HAYNES, JOE R. Determination of the rate of growth of Cantonese capons. *Philippine Agric.* 19(4): 243-252. 1930.—Capons showed no advantage in weight over roosters until 8 weeks after the operation. From then on the capons consistently showed a decided advantage in weight. To maintain their larger bodies the capons consumed slightly more feed but the difference was not great. Thus for every kgm. of weight the capons needed 12.30 kgm. of feed, and the roosters 12.23 kgm. The most economical gains among capons were secured at about 5 months after the operation.—*M. Manresa.*

16894. HUTT, F. B., and A. M. PILKEY. Studies in embryonic mortality in the fowl. 4. Comparative mortality rates in eggs laid at different periods of the day. *Bull. Alabama Polytech. Inst.* 25(1): 32-34. 1930. —Abstract.

16896. STEGGERDA, MORRIS. The relation of domestic fowls to climate. *Ecology* 10(3): 337-342. 2 fig. 1929.—It is assumed that *Gallus bankiva* is one of the ancestors of domestic poultry. The breeding season of these birds is during the dry season. This suggests a reason for the necessity of hot and dry brooder coops for chick raising. The U. S. A. census report shows that the Petaluma district of California, with the densest chicken population per farm, has a spring and summer climate most like that of the area of the original jungle fowls during the breeding season.—*M. Steggerda.*

16897. THOMPSON, WILLARD C. Limiting factors in modern poultry culture. The economic significance of variations in weights of eggs laid by individual hens in poultry flocks. *U. S. Egg and Poultry Mag.* 36(8): [46]-[58]. 1930.—Data given in 9 tables show that individual hens vary markedly as to the number or percentage of first, medium, and small eggs which they may produce during their first or pullet yr. No significant or useful correlation exists between the total number of eggs which a hen lays during the yr. and the number or percentage of firsts, mediums, or small eggs. The poultry breeder cannot use the total pullet year production record as indicative of any certain distribution as to weight or size. Egg size or weight is apparently a separate factor and probably behaves as such in inheritance, and therefore selection for this factor must be added to those which the poultry breeder must bear in mind when selecting breeding stock, if he would seek any certain condition as to egg weight or size in subsequent flocks.—*From author's conclusions.*

CROP SCIENCE (ARVICULTURE)

16900. ABESSADZE, G. [The new species of wheat, Triticum timopheevi Zhuk., and its distribution in Georgia.] [Text in Georgian; summaries in Russian and German.] *Bull. Inst. Exp. Agric. Georgia [Tiflis]* 1929 (2): 59-72. 1929.—Zhukovsky's diagnosis of the species is emended. The sp. is intermediate between emmer and *T. dicoccoides*, but closer to emmer as to growth form, number of grains produced, chromosome number, dimensions of the ear, nervation, and other characters. It is probably a hybrid, with *T. monococcum* as one of the probable parent forms. It must have originated in Georgia long ago, and has been in cultivation there a long time.

16901. ARRHENIUS, O. The optimum soil reaction of the sugar beet. *Indust. & Eng. Chem.* 20(2): 219. 1928.—Pot and field trials (southern Sweden) in which the yield of sugar beets was determined over a wide pH range, showed that the pH optimum is on the alkaline side. The range through which yields of over 90% of the maximum yield were obtained extended, in field trials, from about pH 6.5 to about 8.

16902. ASLANDER, ALFR. Natriumkloratets verkan på åkertistel och andra växter. (The effect of sodium chlorate upon Cirsium arvense (L.) Scop. and other plants.) [English summary.] *Nordisk Jordbrugsforsk.* 1. 1-21. 7 fig. 1931.—Chlorate attacks the epidermis or exodermis and works its way to the inner portion of the roots. In a dry soil the plants develop a corky epidermis and are more difficult to kill. Chlorate applied to the soil killed barley plants growing in daylight in less time than when growing in darkness. Green *Zea mays* plants were more affected by chlorates both in water cultures and in soil than albino seedlings. Of crop plants barley was most sensitive; oats, and especially peas and vetch were less injured. The toxic action is probably due to an oxidation process. Chlorate is decomposed to chloride; and the nascent oxygen given off destroys some sensitive part of the protoplasm. Probably the varying sensitivity towards chlorate shown by various organisms depends on differences in ability to decompose chlorate. Fungi and bacteria can endure a 1% solution of sodium chlorate, which kills higher plants in a few days.—*From author's summary.*

16903. ATWOOD, WALLACE W. The agricultural lands neighboring the east margin of thhe Pacific. *Proc. Third Pan-Pacific Sci. Congress, Tokyo* 2: 1623-1657. 7 maps. 1926(1928).—Statistics of production for various crops, and data on agricultural utilization of land in various countries along the Pacific Coast of the Americas are presented.

16904. AYYANGAR, G. N. RANGASWAMI, and K. KUNHI KRISHNAN NAMBIAR. Sorghum—studies in sowing depths. *Madras Agric. Jour.* 19(5): 205-209. 2 pl. 1931.—Seedings were made in pots. With increased depth of seeding there was a progressive decline in germination and in number of secondary roots, and a progressive increase in the length of the mesocotyl. The underground portion of the coleoptile also tended to be larger. Appreciable differences in length of mesocotyl and coleophyl were noticeable within strains.

16905. BEAR, FIRMAN E. The scientific use of nitrogen fertilizers. *Indust. & Eng. Chem.* 20(1): 65-70. 1928.—Climatic and soil conditions largely govern the type of nitrogenous fertilizer that is best adapted, a wide range of N fertilizers being now available to suit the needs of different soils and crops. In some cases N applied to grass or fruit trees increased drought resistance. The importance of applying N at certain stages of growth for different crops is emphasized. The possibility of extending the use of N to other crops and to many other countries of the world is discussed.—*F. L. Duley.*

16906. BENES, VLADIMIR. Působeni některých vlivů vnějších na zmenu variability obsazeni base pšeničného klaeu. [Influence of certain environmental conditions upon basal spikelet formation in winter wheat.] [German summary.] *Věstník Československ. Akad. Zem.* 6(6/7): 628-633. 1930.—This investigation on 13 winter wheat varieties showed that the % of sterile basal spikelets decreased with increase in plant size; this was true also of varietal lines but in different degrees. Application of Chile nitrate alone slightly increased the % sterile spikelets. Hilling, and irrigating the plants during the head-forming period with an average daily rainfall of 1.6 mm. seemed to have no influence.—*Author's summary (transl. by L. R. Waldron).*

16907. BERTHOLD, TH. Vergleichende morphologische und physiologische Untersuchungen an einigen Tabaksorten. 57p. 25 fig. Dissertation, Technische Hochschule München; Carl Gerber: München, 1929.—Leaf growth, depending upon a number of factors, shows its greatest intensity in the early stages and is not much affected by the time of transplanting. The lower leaves, at the middle period of their growth, have reached nearly their maximum size; the middle and upper leaves grow more uniformly. The final leaf size depends much upon the initial stages. The growth period of the leaves increases from below upwards with an increasing acceleration. The index of length/breadth varies relative to the stage of leaf growth and to the position of the leaves on the stem. The relatively broadest leaves are found on the lower portion of the stem. In general, plants of the cut-type tobaccos transpired less than the cigar-type tobaccos. No explanation is assigned. As absolute dependence of transpiration rate upon number of stomata could not be established; it was thought that width of openings and cuticular transpiration also affected the transpiration rate. Topping the plants and breaking side branches increased leaf area and extended the growth period, particularly with the upper leaves, but decreased the leaf quality. Topping, to be most efficient, should be done as late as possible and high on the plant. Sand cultures showed tobacco plants grow best on a weakly acid soil. Essential differences in nervation appeared in only a few varieties. Various methods of curing tobacco are discussed along with experimental results. The 8 variety groups studied are described in some detail.—*L. R. Waldron.*

16908. BEZRADECKI, SERGUJUSZ. Przyczynek do poznania niektórych ras jęczmienia nagiego. [Strains of Hordeum nudum.] [With English summary.] *Pam. Państw. Inst. Nauk. Gospod. Wiejskiego Puławach (Mém. Inst. Nation. Polonais Écon. Rur. Pulawy)* 11 (1): 28-38. 4 fig. 1930.—The 2 varieties studied, Pulawy and Chełm, belong to the group *falsum* form *B* Att. and are of Asiatic origin. Under Polish climatic conditions *H. nudum* contains a large % of albumin, is early, resistant to diseases and may prove valuable as a fodder plant. The 2 varieties show biometrically significant differences in several characters.

16909. BLEDSOE, R. P. Cotton fertilizers and cultural methods. *Georgia Agric. Exp. Sta. Bull.* 152. 37p. 8 fig. 1929.—At current prices a mixture of $NaNO_3$ and $(NH_4)_2SO_4$ proved to be the most economical source of N, followed by $(NH_4)_2SO_4$ alone, and $NaNO_3$ alone. As sole sources of N, organic materials were expensive. Calurea, leunasalpeter and urea are promising. The most profitable application of $NaNO_3$ was 167-233 lb. per A. In mixtures of cottonseed meal and $NaNO_3$, a ratio of 1 to 4 gave the highest yields but a ratio of 1 to 9 was most economical. "Top dressing cotton with $NaNO_3$ at squaring time gave much poorer results than top dressing at chopping time or applying all at planting time." Limestone was decidedly beneficial when used with $(NH_4)_2SO_4$. Acid phosphate was superior to rock phosphate. The yield from an acid phosphate, blood and muriate of potash mixture was increased by limestone but decreased by ferrous sulphate. The best rate for potash was 30 lb. on Cecil sandy clay. Top dressing cotton with potash appeared beneficial. Cultivation in excess of that needed to kill weeds did not increase the yield. "Best results were obtained from spacing cotton 8 inches apart. Delayed thinning decreased yields."—*H. A. Lunt.*

16910. BONAZZI, AUGUSTO. Relación entre la producción de la caña de azúcar y los terrenos en que ésta crece. [Relation between the production of sugar cane and the soils on which it grows.] *Rev. Agricult. Comer. y Trabajo.* 11(15): 19-23. 2 fig. 1930.—This, the 2nd contribution to the subject of soil-plant relationships in Cuba, shows a direct correlation between the soil Ca soluble in 0.72% HCl and the tonnage production of sugar cane. A study is made of the soil profiles in the valley of the Nipe river and of the production over a period of 7 yrs.—*A. Bonazzi.*

16916. **COSTENOBLE, H. V.** Das Zuckerrohr (Saccharum officinarum Linnaeus) und seine Kultur. *Neues Handb. Trop. Agrik. Lief.* 33. 1-35. [date?]—A general discussion of the culture of sugar cane, including fertilizers and diseases.

16917. **COX, JOSEPH F.** Crop production and management. (The Wiley Farm Series.) 2nd ed. rev. xii+469p. John Wiley and Sons, Inc.: New York. Chapman and Hall, Ltd.: London, 1930. Pr. 13s. 6d.

16918. **DECOUX, L.** L'acidité du sol en rapport avec la betterave à sucre. *Ann. Gembloux* 35(5): 129-152. 1929.—The proportion of acid soil in Belgian beet districts is estimated at 60%. Investigations show a marked diminution of yield and sugar content of beets produced in acid soil. In Belgium the highest yields of beets are obtained in the Polders district, where the CaO content of the soil is highest. The opt. soil reaction for the sugar beet is pH 7-7.5. Liming is necessary in acid soil, otherwise it is to be avoided. Frequent analysis of beet lands is desirable to determine their need of lime.—*L. Decoux (transl. by H. B. Shaw).*

16919. **DECOUX, L.** Les causes de variation de la réaction du sol en relation avec la betterave à sucre. *Sucrerie Belge* 1929(16): 310-332. 1929.—The general causes of variation in soil reaction are: leaching of soil by rain, effects of vegetation, microbic activity, action of sulphuric acid, use of acid or acidifying fertilizers. The use of fertilizer containing lime does not eliminate the necessity for liming.—*L. Decoux (transl. by H. B. Shaw).*

16920. **DEFFNER, CARL.** Der Anbau der Esparsette im Lande Thüringen. Beiträge zur Kenntnis seiner Grundlagen, seines Rückganges und seiner natürlichen und wirtschaftlichen Grenzen. *Wiss. Arch. Landw. Abt. A: Pflanzenbau* 3(4): 595-646. 2 maps. 1930.—Sanfoin appears to have a greater lime requirement than alfalfa. It can be grown only on soils where the subsoil is not below pH 6.0. On light shallow limestone soils the crop may last for 6-8 yrs. or longer while on heavier soils the average is only 4 yrs. When it is brought from poor thin soil to heavy soil the highest yields are obtained after the 2nd yr. Rich soils seem not to be adapted to this crop and it requires some time to become accustomed to such an environment, after which good yields will be produced for about 3 yrs. Sanfoin on good soils does not respond to phosphoric acid but is benefited on poor soils. One of the chief reasons for the diminished production of sanfoin, aside from "sanfoin sickness" and perhaps over-fertilization, is the use of unadapted seed. The use of foreign seed and especially that from southern France has injured the cultivation of sanfoin in Thuringia. A sharp distinction must be made between: (a) its extensive cultivation where it is grown only on the poorer soils and is the only available fodder crop, producing a certain crop even under these unfavorable conditions; and (b) its intensive cultivation where it is grown on the best fields on productive soils as a valuable supplement to alfalfa, because of its value as a horse fodder and as a fat-increasing [milk] fodder for cows. It is desirable that natural selection should ensue within these 2 types of culture of which the former makes up about $\frac{2}{3}$ and the latter $\frac{1}{3}$ of the total acreage in Thuringia.—*C. Deffner (transl. by T. E. Odland).*

16921. **DUTKIEWICZ-MICZYŃSKA, BARBARA.** Rozróżnianie odmian pszenic n podstawie barwienia ziarna fenolem. [Possibility of differentiating varieties of wheat by staining with phenol.] [French summary.] *Roczniki Nauk Rolniczych I Leśnych* 23(1): 93-100. 1930.—According to the method used by Pfuhl 50 seeds of each variety were spread out in a petri dish moistened with 2 cc. of 1% solution of phenol and allowed to remain for 4 hr. After drying for 24 hr. the seeds were examined. One of the varieties exposed to phenol for 4 hr. did not change in color. The others colored more or less intensely, changing their normal pigment to yellow, bright brown, dark brown, and black. The colors were determined by the used of a color chart. Both winter and summer varieties were examined. 20 varieties were examined at 2 different times. Examination of the 2 lots of materials showed that the color of the seed induced by the action of phenol is characteristic of the variety and not dependent upon age or locality. Seed of all varieties of *Triticum vulgare* which were exposed to the action of phenol for a longer time were colored black, but the hard wheat (*T. durum*, variety Pulawy) colored only faintly after several days and never became black. Anatomical study showed that phenol colored only the testa and pericarp; the inside of the seed, including the nucellus, did not stain. Although this method of determining varieties of wheat doubtless has its limitations, it may help to fix the identity of varieties. —*Author's summary (transl. by M. T. Munn).*

16922. **ENLOW, C. R., and W. E. STOKES.** Lawns in Florida. *Florida Agric. Exp. Sta. Bull.* 209. 20p. 11 fig. 1929.—Supplemented by an article by J. R. WATSON and H. E. BRATLEY entitled The Chinch Bug on St. Augustine Grass, this paper presents general information on the most important species of lawn grasses, preparation of seed beds and renovation of old lawns, care of established lawns, and upon species especially suited for winter lawns.—*J. W. Wellington (courtesy Exp. Sta. Rec.).*

16923. **ERICSSON, GUST.** Kort redogörelse för jämförande försök med några rågsorter vid Sveriges Utsädesförenings filial på Holms säteri 1917-1930. [A report on yield trials of rye 1917-1930 at the Svalöf Branch Station in Holm.] *Sveriges Utsädesför. Tidskr.* 41(1): 58-66. 1931.

16924. **[EVKO, V. E.]** ЕВКО, В. Е. Опыты с удобрением табака на южном берегу Крыма за время 1911-1919 г. г. (Fertilizer experiments with tobacco on the southern coast of Crimea in 1911-1919.) [English summary.] Известия Государственного Института Табаковедения [*Bull. State Inst. Tobacco Invest.*] 55. 1-41. Portrait. 1929.—When 82 kg. of N as $NaNO_3$, 52 kg. of P_2O_5 as superphosphate, and 75 kg. of K_2O as the sulphate were applied, the mean yield increase was 86%. Of this increase 75% was due to the nitrogenous fertilizers and 10.5% to potash and superphosphate. The potash and superphosphate with the $NaNO_3$ were applied in spring, the remaining $NaNO_3$ in autumn. The autumn application of fertilizers has some advantages, but the triple combination applied in spring gave nearly the same results some years. When 18 tons of manure were added to the mineral fertilizers, applied as above, the mean increase in yield during 5 yr. was 30% for the P-K combination, 28% for the N-P combination, and lesser increases with other combinations. Manure as a fertilizer furnished chiefly N, less potash, and least phosphoric acid. When mineral fertilizers were applied in spring, manure applied previously in autumn showed less effect, but was again chiefly a source of N. With different quantities of manure applied alone, increase in yield paralleled increase in quantity of manure. The greatest mean yield increase from manure alone for the 5 yr. period was obtained from an application equivalent

to 540 kg. of N. This increase was 55% as against 75% from 82 kg. of N from $NaNO_3$, with P and K. With 41 kg. of N, as $NaNO_3$, 33% increase was obtained.—*From author's summary.*

16925. **FENTON, E. WYLLIE. A botanical study of pasture plots.** *Ann. Appl. Biol.* 17(3): 522-548. 1930.—Botanical analyses and estimates of total yields were made yearly during 1923-1927 of pasture mixtures in plots two yards square. There was a marked tendency to develop a flora of the same proportions in all plots. This change occurred in 3 stages; (1) the dominance of rye grasses and red clover, (2) increase of cocksfoot, timothy, wild white clover and fescues, (3) stabilization of the flora with dominance of cocksfoot and a steady proportion of perennial rye and wild white clover. In general the order of aggressiveness was: Italian rye, perennial rye, red clover, cocksfoot, wild white clover, bent and rough-stalked meadow grass, timothy, fall and meadow fescue.—*J. A. Bizzell.*

16930. **GARBARS, J. Vasaras kvieši. [Wheat varieties.]** *Lauksaimniecibas Menešraksts [Riga]* 1930(7): 436-444. [German summary p. 3-4, in back of issue.] 1930.—The Lettish wheat varieties Rubin, Janetzky and Extra Kolben are those most resembling the foreign kinds under trial. The period of vegetation available in Latvia for spring wheats is practically 110 days. In spite of their short vegetative period, the Canadian varieties Prelude, Garnet, Marquis and Reward are not adapted to the Lettish climate, lacking vigor and tending to lodge. This also applies to varieties from Italy and Jugoslavia. The local spring wheats consist mainly of a mixture of different botanical forms, those considered most valuable being white and brown awnless sorts. The harvest is made more difficult because of this mixture since the different kinds do not ripen at the same time. All local wheats have a low weight per 1000 kernels and the quality of grain is good, for the most part. Experiments have shown that under Lettish conditions a seeding rate of 250-300 kg. per ha. gives best results. The selection and breeding of wheats is being undertaken in conjunction with variety trial work. The objectives are (1) securing productive kinds, (2) shortening the vegetative period and (3) improving quality. The best spring wheats from the Stende station thus far are 216, 26, 28 and 3.—*L. R. Waldron.*

16931. **GASSER, E. The utilisation of refuse.** *Internat. Rev. Agric. Pt. 1 Mo. Bull. Agric. Sci. & Pract.* 21(1): 22-32. 5 fig. 1930.—Difficulties in utilisation of refuse lie in its bulk and in the variability of its composition. Green refuse, such as undecomposed straw, far from producing a beneficial or fertilizing action, may even have a definitely harmful effect. Fermentation produces the right degree of decomposition of the more resistant substances, disintegrates straw and other refuse, forming the complex humus on which a large part of the fertilizing capacity of a manure depends. This treatment of refuse also renders the fertilizing elements—N, P, K—assimilable. This form of manure may be superior to others in that, in addition to the direct action of its nutritive elements, it has an indirect action in favoring the assimilation of the nutritive elements already in the soil or applied as chemical fertilizer; moreover, it has a beneficial action on the physical, chemical and biological properties of the soil.—*From author's summary.*

16933. **GÓRSKI, M., i J. KROTOWICZÓWNA. Działanie obornika i nawozów mineralnych na plon machorki i zawartość nikotyny. [Effect of stable manures and mineral fertilizers on yield and nicotine content of Nicotiana rustica.]** [German summary.] *Roczniki Nauk Rolniczych i Leśnych [Poznań]* 24(1): 1-15. 1930.—Field experiments carried on for 3 yr. led to the following conclusions: *N. rustica* requires large amounts of nitrogenous fertilizers, hence it is advisable to apply well rotted stable manure in early winter. For heavy yields it is necessary to apply additional N. With a medium application of stable manure additional N is necessary but no K and P fertilizers are required. N fertilizers have a marked effect on the nicotine content of the leaves. During 3 yr. the nicotine content was much higher on plots receiving complete fertilizers than on plots without N. Lack of K also lowers the nicotine content but to a lesser degree. Lack of P however increased the nicotine content slightly.—*F. F. Halma.*

16944. **KOCK, H. Ertragssteigerung im Zuckerrübenbau durch frühe Aussaat and spätere Ernte.** *Zuckerrübenbau* 12(5): 73-77. 1930.—Experimental results show that early seeding and delaying of harvest time raises the raw sugar yield (from beets) without increasing the cost of production.

16945. **KRÄNZLIN, G., und A. MARCUS. Baumwolle. [Cotton.]** (*Wohltmann-Bücher Bd.* 9.) 169p. 24 fig. Deutscher Auslandverlag Walter Bangert: Berlin-Charlottenburg und Leipzig, 1931.

16946. **LIEB, PERCY. Der Kalkphosphorsäurefaktor der gelben Lupine (Lupinus luteus) und seine Beziehungen zum Ertrag dieser Pflanze.** *Wissenschaftl. Arch. Landw. Abt. A. Pflanzenbau.* 3(1): 124-160. 1930.—The effect of the lime-phosphoric acid factor on the yellow lupin is not definite. The phosphoric acid and lime content of the plant is not influenced by the P of the soil as determined by Neubauer's method or by the lime soluble in HCl. Nor is the plant content of these elements affected appreciably by variations in the phosphates and lime applied to the soil. The ash content of the plant varies with the physical characteristics of the soil, together with the climatic conditions. Analyses of plants and the soil in which they are grown suggest no general conclusions, although in extreme cases some relationships may exist.—*From author's summary (transl. by O. Owen).*

16947. **LIEBER, und H. MÜLLER. Die Trocknung von Saat- und Körnermais. [Drying seed and grain corn.] Ergebnis mehrjähriger Untersuchungen im Auftrage des Reichsministeriums für Ernährung und Landwirtschaft, der Deutschen Landwirtschafts-Gesellschaft und des Reichskuratoriums für Technik der Landwirtschaft.** *Mitteil. Deutsch. Landw.-Ges.* 45(37): 777-779; (38): 806-808. 5 fig. 1930.—Temp. up to 50° C. may be used in drying maize for seed without lessening the germinating ability. In natural drying sheds the main factor is the vertical depth of the layer of corn, 0.7 m. appearing satisfactory.—*F. Foulds.*

16948. **LUNDEN, AKSEL P. Forsøk med tidligpoteter på forsøksgården Vollebekk og på endel spredte felter i årene 1922-27. [Field experiments with early potatoes during 1922-27.]** [With English summary.] *Meld. Norges Landbrukshøiskole* 10(3/4): 145-180. 1930.—The performance of varieties with respect to earliness, yield, tuber size, shape, weight and resistance to dry rot are given. The length of the growing period is considered secondary to yielding power and size. Seed potatoes of different size, but presumably of the same maturity, showed great differences. The number of stems and harvested tubers decreased with decreasing tuber weight, while the size of harvested tubers increased. The net yield is highest for the medium sets (50 gm.).
